ANNEX  
Dict.

0021

TO THE RIGHT HONOURABLE

**SIR JOSEPH BANKS, BART.**

KNIGHT OF THE BATH,

PRESIDENT OF THE ROYAL SOCIETY.

SIR,

YOUR kind permission of addressing these volumes to you, as it affords me an opportunity of acknowledging the many obligations you have conferred, I received with the greatest satisfaction. A work, nearly approaching in its object that department of science in which you are so eminent; which rests on the observation of Nature in all her varied forms as her securest foundation;—in fact, THE NATURAL HISTORY OF THE BODY AND MIND, cannot, I trust, to you be unacceptable. Should it appear to be executed in a manner worthy the approbation of yourself and the public, my highest ambition will be gratified.

I have the honour to be, SIR,

Your very obliged and faithful

Humble servant,

**BARTHOLOMEW PARR.**

*Exeter, November, 1808.*

## P R E F A C E.

---

**I**F a dictionary be sometimes the refuge of indolence, it is an useful resource in circumstances of emergency. It offers a collection of opinions, at one view, and within moderate limits, suggests hints from sources beyond the reach of common acquirements, beyond the extent of a common library, and leads the inquiring mind into paths of which he might not have suspected the existence, or been unable to pursue the intricacies. If these be the general advantages of a dictionary, this form is peculiarly applicable to a science where emergencies frequently occur, where the time for reflection is short, and the practitioner, from anxiety and distress, unfitted for cool consideration. A man of sensibility is, in such circumstances, obliged to conceal his pangs under the appearance of composure, and to cover doubt and hesitation by a seeming calmness and confident decision. His situation, also, is often little adapted for deriving assistance from numerous authors, in different languages; nor is his mind always so carefully regulated by education as to pursue a chain of reasoning strictly inductive, or to detect error, under the semblance of plausible improvement. To bring before him, therefore, the opinions of distant eras and countries, to offer what the ablest professors have thought, to describe how they have acted, must be a valuable acquisition to one class, while, to the intelligent and experienced, it may be no useless remembrancer—an index to those sources of information which may be more minutely, and, therefore, more advantageously followed. It is not the least of the advantages of the following pages, that they detect many reputed discoveries of modern times, in the neglected authors of former periods; and the sanguine admirer of what is new may learn, from the reception which any proposal has formerly experienced, to appreciate with greater accuracy its value.

To attain these objects has been the anxious wish of the author; and, with these in view, he can scarcely have entirely failed. This work is not the design of a moment: projected in the eagerness of youth, it is completed in the maturity of experience; constantly kept in his sight; a deposit of the accumulated stores of reading and observation.

To excel former works, under this title, at least such as had appeared when the plan was first laid, seemed no very difficult task. They chiefly consisted of definitions and short explanations, or were diffuse collections, from different authors, in the same form, frequently in the same words. He who consulted the latter work might well exclaim, *inopem me copia fecit*; while those who applied to the former caught the shadow, instead of the substance—learnt the etymology of a title, when they wanted a remedy for the disease.

The lexicon of EROTIAN (perhaps HERODIAN), the Voces Græcæ of JULIUS POLLUX, the lexicon of HERODOTUS LYCIUS, and others, published by HENRY STEPHENS, with the Œconomia of FÆSIUS, appended to his edition of Hippocrates, are scarcely more than elucidations of the terms used in the ancient authors. DE GORRIS (Gorræus) was more full in his explanations, and more extensive in his views. The Definitiones Medicæ, first published in 1564, afterwards, by his grandson, in 1622, contain a satisfactory view of medicine, as it was left by the ancients, and no imperfect account of the medicinal plants described by Theophrastus and Dioscorides. BLANCHARD seems chiefly to have copied Gorræus, and scarcely advances beyond the definitions of his predecessor. CASTELLUS is equally unsatisfactory; but the edition of *Bruno*, published at Geneva, in large quarto, and the still more extensive one which appeared at Naples, in 1761, are valuable, though unequal collections. The former contains the Arabic, the Hebrew, the Greek, French, and Italian appellations, added by Bruno, under the title of *Mantissa Tetraglotta*, and the latter many of the modern improvements.

Our own countrymen received, early in the last century, the assistance of QUINCY, who has transcribed and abridged the definitions of his predecessors, adding the principal doctrines of the mechanical philosophy, and their application to medicine. Indeed the latter seems to have been his chief object; and, when Newton had, with the assistance of mathematics, expanded our view, and found the solar system subservient to one principle, gravity, it was supposed that the same success would follow their introduction into every science; and nothing but demonstration was talked of and expected. This work has been lately published, with numerous improvements, by Dr. Hooper; but within limits which necessarily preclude any very extensive disquisitions.

About the middle of this century, DR. JAMES offered a vast work of this kind to the public, in three ponderous folios. The erudition which he displays is extensive, and his explanations are often satisfactory. He has collected all the learning of his predecessors, preserved their controversies, and added whatever a diligent attention to the works of the ancient physicians could contribute to the former stock. In the more strictly practical part of his dictionary, he has collected, with the same care, and has copied, not always with sufficient discrimination, the opinions of different practical authors. The diffuseness of his

language contributes, however, to lessen the advantages which such a work ought to possess, as a ready resource in cases of difficulty; nor, in the mass of contending opinions, is it always easy to collect those comprehensive views, which will at once lead to a decisive and discriminated practice.

Some later dictionaries in our language are, in general, slight glossaries, with slender claims, which may be fairly allowed. One other work, of a more respectable bulk, and more plausible pretensions, we may be, perhaps, expected to notice; but any observations which we might offer would appear to be dictated rather by the spirit of rivalry than of sound criticism. We wish not to disturb the opinions of those who approve it.

There are numerous collections from authors, sometimes of reference only, but more often copies of detached passages, arranged, in many instances, alphabetically, which, though not properly dictionaries, demand some attention. While the works which have been styled definitions and glossaries preclude disquisitions, these reject mere verbal explanations. They approach nearly to our prototypes, particularly the dictionary of Dr. James; but are different in their pretensions, as well as in their execution, and of unequal value.

MORONUS first published his *Directorium Medico-practicum*, at Leyden, in 1650, professing to give a list of the opinions of the most eminent physicians, who had written either in the form of consultations, epistles, replies, observations, or histories on different diseases. This Directory was published in octavo, and, thirteen years afterwards, a more enlarged edition, by Sebastian Scheffer, in quarto, appeared. Without impeaching the accuracy of Moronus, we may remark, that his work is very unsatisfactory, from the general objects of his references. Under each disease we find a list of authors, without the slightest hint in whose volumes we are to seek the pathology or cure, by whom the remedies are discriminated and adapted with the most scientific care, or where the greatest number of idle fancies obscure the merit of attentive observation.

The SYLVA MEDICA of J. G. Walther is far more valuable. His references are copious and distinct; his synonyms, including the barbarous and obsolete appellations, numerous; his chemical compositions, in which, however, he could not soar beyond the state of the science at that time, detailed with accuracy. His work was published at Bautzen, in Germany, 1679, in quarto, illustrated by an index of authors and diseases. Had Walther fulfilled the promises of his title, the Sylva would have been highly useful; but his omissions are numerous, and his references so general, that they are often of little real value. A similar work was published at Frankfort, previously to the former publication, by M. MARTIANUS LIPENIUS, in folio, 1759, with a copious index, which we have been unable to procure.

Walther was followed by MANGETUS, a most voluminous collector, who published his *BIBLIOTHECA MEDICO-PRACTICA* at Geneva, in 1698, &c. in four thick folio volumes; and, twenty-six years afterwards, the *BIBLIOTHECA CHIRURGICA*, in volumes equally numerous and bulky. Each collection is a tedious cento, from different authors, without a scientific arrangement, almost without any apparent design. From many vast collections, the observations are selected, without a reference to the volume, and the editions are seldom so carefully distinguished as to ascertain the real merit of the passage transcribed. Yet Mangetus was not merely a tasteless compiler, but a man of sound judgment and accurate discrimination, as he has evinced by his critical remarks in his *BIBLIOTHECA SCRIPTORUM MEDICORUM*.

BONETUS was a collector almost equally indiscriminate, and his *POLYALTHES*, a posthumous work, was published at Geneva, in 1691. The title is derived from the name of a supposed daughter of Æsculapius, who appears to have received it from her extensive powers of healing. This work, however, scarcely belongs to the present subject, since it consists of a close, but extensive commentary on the syntagma of J. JOHNSON, the *IDEA MEDICINÆ UNIVERSÆ*. A former work, entitled *MERCURIUS COMPILATIVUS*, denominated from the statues of Hermes, placed in the highways, to point out the road, was more professedly a compilation, in an alphabetical order, but without a nice selection of authorities. In the following year, the same author's *MEDICINA SEPTENTRIONALIS COLLATITIA* appeared, containing the discoveries of the Germans, the English, and the Danes, chiefly from their transactions, in an order not alphabetical.

The *ENCYCLOPEDIÆ* of DOLÆUS are similar collections, arranged according to the subjects: the *Encyclopedia Chirurgica* was an early work, published in 1659; the *Encyclopedia Medica* only in 1691.

This inundation of compilations, at the end of the seventeenth century, appears to have exhausted the spirits and the industry of collectors, since several years elapsed before a similar attempt was published. The first work of this kind seems to have been the *SYNOPSIS* of DR. ALLEN, a physician at Bridgewater, in octavo, which, though not in alphabetical order, contained the opinions of different physicians on the principal diseases, and it was one of the first English publications in which the opinions of Boerhaave were popularly detailed. A third volume appeared, in English, in 1756.

The *LEXICON PHYSICO-CHEMICUM REALE* of G. H. BEHR was published in 1738, in quarto, and followed by a smaller work, entitled *BIBLIOTHECA MEDICA*, by CHRISTOPHER WILLIAM KESTNER. Neither of these have we been able to procure.

A French work, PLANQUE'S *BIBLIOTHEQUE CHOISIE DE MEDECINE*, appeared at Paris, in

1738, and eight successive volumes were published, at different periods. It contains, however, extracts only from the periodical works of France, and other countries, but chiefly from the former, with little selection or discrimination. It is, in every respect, a trifling collection.

The most important publication, in this form, is the *BIBLIOTHECA CHIRURGICA* of *JEROME DE VIGILIIS VON CREUTZENFELD*, in two volumes quarto, published at Vienna in 1781. This is an excellent collection, and more valuable, since the *Bibliotheca Chirurgica* of Haller is, in so many respects, imperfect and erroneous.

The last compilation of this kind is the most valuable, the *INITIA BIBLIOTHECÆ PRAC- TICÆ*, by *PLOUQUET*, published at Tubingen, in eight volumes, small quarto, to which two supplementary volumes were afterwards added. It includes a catalogue of the best authors, under the different diseases, each arranged alphabetically, distinguishing those who have treated generally on the complaint—the causes and remedies assigned and recommended. The references are particular, accurate, and numerous; perhaps more numerous than select. The author has collected from every source, and seems to possess a most accommodating belief in all the tales of wonder, from *Schenkius*, the authors of the *Ephemerides Naturæ Curiosorum*, and those whose narratives rather excite contempt than confidence. The remedies, too, are frequently the most trifling and ridiculous. But, on the whole, this collection is full, correct, and instructive.

A Dictionary of Medicine was, some time since, published by *Dr. Motherby*, and continued, in successive editions, by him and *Dr. Wallis*. When a new work of this kind was required by the public, it was supposed that it was requisite only to add the modern improvements to the ancient structure; nor was it suspected that what had received the sanction of the public, in five successive editions, could be wholly contemptible. It was, however, soon discovered that the substance was no less erroneous, than the form was unpleasing; that, to render it instructive, without offending the reader of taste and education, required more attentive care than was necessary for a simple revisal. The discovery was not, however, made before a part of the first volume had been printed, which has occasioned some of the unconnected sentences of the former work, and some of the disgraceful references, to remain. When the defects appeared, in their fullest view, the whole was examined with a severer scrutiny, and the subjects investigated in the original authors; nor was a single opinion allowed to remain, which had not the support of authority or experience. The work is, consequently, to be considered as original, and the names of *Motherby* and *Wallis* are consigned to the oblivion, from which they had, for a time, escaped, though their labours have been lately copied, often servilely, in publications professedly original.

If the necessary extent of a work of this nature be considered, it will be at once obvious

that the bulk should not be unreasonable, and it has been consequently limited to two quartos. The requisite additions were supposed sufficient to supply the rejected parts of the folio. But absurdity mocks calculation, and numerous observations and disquisitions, at first studiously retrenched, might, we found, have been retained, since much space was gained by the smallness of the type, and the size of the page; more, by avoiding controversies, employing a concise, comprehensive style, increased vigilance in detecting absurdity and error. Though the utmost care was exerted to avoid its necessity, an Appendix thus became expedient; and, when once admitted, every means of increasing its utility was adopted. The words suppressed were few; but it soon appeared that numerous additions and corrections might be useful. In a long period, destined to the study and practice of a profession, under circumstances which brought every new production before his eyes, and called for his decision, the author thought that the principal questions were decided in his mind, and had little doubt of rendering his work consistent. After the lapse of several years, however, subjects must assume a different hue; and the medical questions are too numerous for constant recurrence. When, therefore, the subjects were again reviewed, some facts appeared in a different light, and it was by no means proper that truth should be sacrificed to consistency. The change of opinion was, however, pointed out in the concluding article; and, by the assistance of the Appendix, the references were not only better compacted, but the inconvenience from these variations was avoided. The minuter errors, which inadvertently crept in, before the imperfections of Dr. Motherby were fully discovered, are by this means also corrected, and the whole work is rendered more regular and consistent. It is not, therefore, an appendix, but amendments, that might make a part of another edition. The author becomes a critic on himself, and, he thinks, has sometimes proved a severe one. For this reason, he has changed the title of the additional part, and styled it, "Second Thoughts," *CURÆ POSTERIORES*.

A new work of this kind, from the peculiar circumstances of the era, was required. Since the last publication of any tolerable compendium of medicine, no inconsiderable progress had been made in every branch. Every quarter of the globe, and the new continent, if Australasia merits this name, have been visited, with anxious care, by the eager votaries of natural knowledge; and the highest Andes have not escaped the researches of Humbolt and his coadjutors. From these investigations medicine and natural history have gained considerable advantages; and if new remedies have not added to the length of lists already crowded, we have ascertained, in many instances, the true botanical relations of those formerly known; and, from the improvement of the natural system, in the hands of Ventenat, the successor and pupil of Jussieu, the first of the French botanists, we can, in many instances, supply what accidents, or the chances of war, may for a time deny.

Chemistry, during this interval, has become a new science, and the refinement of its analysis has been applied to the most important purposes of medicine. We now know, with

the most minute accuracy, the nature of the blood, and the *greater number* of animal fluids; we know, too, that the circulating mass is scarcely changed by diseases, once supposed to reside exclusively in it. The natural and morbid states of the secreted fluids are also, by the application of this science, more easily understood, and we are thus taught to disregard many imaginary sources of terror.

The difference between the animal and vegetable mixed, and again, between vegetables and minerals, is now, also, more clearly defined: the limits of each are ascertained; and, though, in the progress of our knowledge, we find nature, as usual, passing, by almost undistinguishable shades, from one to the other, we can assert, with some confidence, from what points they diverge, and where they coincide. If we find the fibrin in bran, and the prussic acid in bitter almonds, we cannot, for a moment, mistake them for animal substances: if we discover the phosphoric acid in the human body, and the kali in the leucite, we shall not mistake one for a mineral, nor the other for a vegetable.

In the analysis of the vegetable substances used in medicine, and in ascertaining the real chemical nature of mineral preparations, whose utility has been established by the most extensive experience, the same science has lately become most beneficial to mankind. These acquisitions have improved and simplified our pharmacopœias; nor are our formulæ now crowded with heterogeneous, discordant ingredients, ~~our~~ mineral waters loaded with imaginary and incongruous impregnations, or disgraced by contradictory powers. We approach the era when the vegetable principles will be still more clearly understood, when the gum and the resin will not be the ultimate results of our analysis; but we shall, probably, be able to offer only the rudiments of such investigations, under the additions to the article *Cortex Peruvianus*.

Improvements in *ANATOMY* have been less splendid. Indeed, whatever the minutest accuracy could ascertain, in the investigation of the structure of the human body, was apparently found in the works of Winslow, Haller, Morgagni, Monro, and Hunter. Nature is, however, inexhaustible; and the ample harvest of former anatomists left valuable gleanings for Camper, Walther, Scarpa, Sandifort, Comparetti, Soemering, and Loder. Comparative anatomy has been, in the later periods, cultivated, with equal success, by Spalanzani, Cuvier, and Blumenbach.

If the improvements which have been made in the explanation of the various functions of the human body are examined, the branch of medicine entitled *PHYSIOLOGY*, we shall not have much reason to congratulate ourselves on extraordinary success. The minuter operations of nature are carried on in the first "elements" of our system: the sacred shrine of the goddess is inaccessible. The agents are also the living organs, and we can scarcely

ascertain in what life ultimately consists; the operations of the body are affected by the mind, and we know neither the nature of the latter, nor the medium of the connection. The principal improvements, therefore, in this branch will consist in simplifying our views, in generalizing our facts, and, by strict induction, clearing the subject from erroneous theories. In a few instances, some advances have been made; but, while life itself is mysterious, the laws by which its operations are regulated will remain in equal obscurity.

**PATHOLOGY** will partake of the imperfections of physiology; but it fortunately happens that although the theory may fail, the means of relief are within our reach. In this branch of medicine also our objects are more simple and discriminated. It has been the fashion to ridicule nosology; but, since the publication of Dr. Cullen's system, greater progress has been made in accurately distinguishing diseases than in the five hundred preceding years. The various kinds of asthma, cutaneous diseases, fevers, particularly those of the puerperal state, with many other complaints, confounded even in the best authors, are now clearly distinguished. It is singular, that concussions of the brain have been very imperfectly discriminated from the effects of fracture, of depression, and of extravasation, in works of established reputation.

**THE PRACTICE OF MEDICINE** has received equal improvement in the simplicity of its views, and the distinctness with which the circumstances of diseases are discriminated. It no longer consists of a farrago of medicines, accumulated merely because each has been recommended, nor of general formulæ, without an object; but the views of the practitioner are directed by the changes often suggested by indications, and these are produced by the simplest means. Our medicines also, as their properties are more distinctly known, are selected with juster skill, with more pointed precision, and we trust that something has been added in this work to the distinction of their more peculiarly appropriated virtues. New medicines glitter for a time, like meteors; and the power of every new remedy is, during the prevalence of the fashion, undoubted. The scepticism of advanced life distrusts the fallacious glare, calmly inquires, and cautiously tries, before it decides. Conscious of the various sources of error, the resolution is at last adopted with doubt and hesitation. Yet no one is wholly free from the temptation of novelty: each is apt to trust with confidence to his own plans; and, in the hands of a discoverer, we always find a medicine infallible.

**SURGERY** is still more improved by the general discrimination and boldness of modern practitioners, and by the happy daring of distinguished characters in this department. If it has been our lot sometimes to detract from the civic wreath, by sullyng the gloss of novelty, we mean not to lessen their fame. In them it may have been the first suggestions of bold decision, tempered by judgment, by experience, and a confidence in their own powers; nor should the

occurrence of the same ideas in a forgotten author lessen the credit which such improvements claim. While surgery is thus more distinct in its views, and more decisive in its conduct, it has equally succeeded in shortening the sufferings of the patient, by hastening the cure. The operations of surgery are now performed with equal intrepidity and skill.

In the pursuit, however, of novelty, it must not be forgotten that our ancestors were neither blind zealots nor deliberate homicides. They must not be blamed because they were unable to anticipate the discoveries of future eras; and their merit must rather be appreciated by the situations in which they were placed, or the means in their power. They observed diseases individually, but spoke of them collectively: they did not always distinguish accidental from pathognomonic symptoms; and, from the farrago of medicines which they employed, it was difficult often to determine whence the advantages arose. Yet their attention and fidelity deserve our regard; their judgment often claims our respect, and their sagacity our praise; nor will the practitioner recur to even their loosest narratives without interest and advantage. In the conduct of this work we have often repaired to the original authors, and been sometimes amply repaid. Boasted discoveries have been detected in their germ, and infallible remedies in the forgotten pharmacopœias of the middle ages.

A dictionary, though it apparently consist of scattered limbs, often incongruous, should, however, be rendered as much as possible a whole: one spirit should pervade it, and system should collect its diverging rays into a focus. Systems, indeed, are often employed to distort facts for their support, or to conceal those which should oppose them; and the numerous idle theories which, like passing spectres, have glared and vanished, at once, rendered the word suspicious. To be aware of each abuse is the best means of avoiding it; but by the term system we rather mean the reduction of facts to general principles, which may connect and unite them, should the principle itself be erroneous. Thus, if in every instance we find spasm and convulsions connected with debilitating causes, it is no injury to science to consider them as arising from debility; and they evidently consist in irregular action. Debility, thus connected with irregular action, is a bond of union of the most extensive influence, and brings into one view observations widely scattered. Should the principle be erroneous, it will be at once discovered, when brought to the test of observation and experience; and if these oppose it we shall be soon led to sounder views. It cannot be injurious but from suggesting inert practice, useless innovations, or dangerous refinements. Such generalizations, in the hands of Bacon, Newton, and Herschell, have been highly beneficial to science; nor can these weapons be wholly ineffectual, if wielded by inferior powers. In the present circumstances, no facts have been distorted to support a theory: where the principle can only be carried to a certain extent; where, in some of its bearings, the security fails; and where facts are apparently discordant, the reader is at once apprised.

The advantages of such connected views must be obvious. In the scattered practical observations, opinions have differed as widely as the statures and complexions of the authors. Each can only be with justice appreciated on its own foundation; and the motley character, a work compiled with little discrimination, must soon render it disgusting. If, in the course of the inquiry, any general connection, any link, which will connect the apparently discordant facts to one principle, be discovered; if this link be furnished, as has often happened, by the author's own limitation of his plan or remedy, these facts will at once combine with the others, and form a dependant part of the whole. It will thus be more easily retained, and contribute to illustrate the collateral subjects.

Were a work of this kind a mere compilation, even the same article would not be consistent; for it is not easy to find the author from whom the pathology, and the whole of the practice, could be properly taken. Should the talents of each be equally exerted in every part, new views and new plans must in many instances have arisen. If, then, the plagiarist cannot find the whole in any work, he must constantly submit, like many of our predecessors, to inconsistencies. He may detail the pathology with ability; but his practice will be at variance. He may explain the structure of a part; but it will have little connection with the elucidation of its functions. Were the practice of Burserius, for instance, appended to the pathology of Cullen, without those explanations which the different views and designs of each author would suggest, the reader might suspect that two distant parts of a work had by accident joined; or, if the theory of Darwin were followed by the solemn indications and the judicious practical remarks of Van Swieten, they would appear the "*ægri somnia*," and might justly be styled "*vanæ species*."

---

IN THE CONDUCT OF THIS WORK it has been the great object to collect information the most extensively useful within the shortest compass: a concise and comprehensive language has been, consequently, adopted. In detailing the sentiments of other authors, their opinions, rather than their words, have been preserved; we thus not only avoid the tautology and diffuseness too common among the greater number of medical writers, but connect the subject with other parts of the work, and point out its influence on other branches of the science. A fertile source of prolixity, in medical publications, is the detail of cases, which, though sometimes useful in illustrating the author's doctrine, more frequently shows its weakness. As these cases are crowded with circumstances, often uninteresting, the general result, and those portions of the narrative which limit or influence the consequences, are alone preserved. Controversies have been, for the same reason, avoided. Of these it is sufficient to point out the existence, and the works in which they may be most advantageously examined; and if a little dogmatism in decision sometimes appears, this tone has not been adopted without the most attentive consideration of the different and opposite arguments.

As the form is that of a dictionary, and the object to afford a ready resource in emergencies, each article is designed to be in itself satisfactory, that, in the moment of necessity, it may not be requisite to turn over two quartos. For this reason, in each will be found an abridged view of the subject, with an immediate reference to those pages where it is treated more satisfactorily. The references are, indeed, the bond of union between the distinct portions of the work, and the connection has, by their means, been kept up with peculiar care. Though sometimes numerous, they are select, and, we trust, satisfactory.

ANATOMY is the foundation of the whole science, and the structure of the different organs is essential in the explanation of their functions; while, in the practice of surgery, the minutest investigation of the course of the arteries, and the exact situation of the more important organs, can alone insure success. In a work of this kind, however, extreme minuteness is unnecessary; for dissection alone can convey those accurate and vivid ideas which must direct the surgeon's hand. The descriptions are chiefly designed to convey general instruction, or, in the more important parts, to assist the recollection of what dissection had, at an earlier period, taught. The great difficulty was, therefore, to steer between accounts, uselessly vague, or unnecessarily minute; nor is it to be expected that every reader will concur with the author in his determinations in these respects.

In PHYSIOLOGY the latest opinions have been detailed, and these have been carefully connected with former theories, sometimes showing that modern philosophers have not always those considerable claims to originality which have been so liberally allowed. PATHOLOGY, in modern medical publications, is almost a new science; but the facts which illustrate the natural history of the human body, in a morbid state, connected with the appearances on dissection, have been collected with great diligence, often from the almost forgotten pages of Morgagni, or the neglected ones of Bonetus; assisted by numerous instructive narratives from the different collections of "Essays," "Observations and Inquiries," and "Transactions," in our own language. This part of our labour teaches one melancholy lesson, that many diseases are beyond the reach of human art, whether the changes be considered as causes or effects. But it also represses overweening confidence, prevents disappointment, and, by a sagacious prognostic, secures the credit of the science and the practitioner. The general pathology is that of Gaubius, with the judicious retrenchments and additions of Cullen, farther improved by the new discoveries of the chemical nature of the animal fluids; for, no work has been copied through the whole article, except where the quotation is distinguished, in the usual way, by inverted commas, or where the general substance is acknowledged.

The PRACTICE OF MEDICINE has been detailed with unusual care. The plans of the most approved and scientific authors have been carefully considered, and, whatever science or empiricism has at different eras suggested, is carefully noticed, with those distinctions which

may render the discovery more useful and effectual. To accumulate every medicine which has been recommended, in the manner of Lieutaud, would not be difficult; but to discriminate the circumstances, in which alone each plan will be effectual, is not equally easy, though such discrimination can only render the directions valuable or salutary. A real dogmatic practice, viz. pursuing indications, arising from the knowledge of a proximate cause, would gratify the pride of science, and be most advantageous to the patient. The expectation is, however, vain; for in very few instances can an immediate cause be established. Though this, however, be beyond our attainment, we can, in many cases, ascertain general principles, which will assist our practice. Whatever be the cause of fever, for instance, the balance of the circulation is evidently disturbed; and to restore the equilibrium contributes very essentially to the cure. It has been a great object, through the whole work, to ascertain such principles; but they often fail, and the physician must then pursue, under proper regulations, the *juvantia* and *lædientia* which observation has ascertained. When the medicine is determined, the form is easily adjusted; but, except in a very few instances, what are styled formulæ are omitted. These are the refuge of ignorance, indolence, or quackery. Every one can transcribe what is printed, and every old woman will eagerly affix a name to a disease: few will venture, from a class of medicines, to select the particular remedy or the dose. If it were possible always to discriminate the circumstances in which the different plans are advisable, formulæ might be added; but, to those who can distinguish, they are useless, and to others furnish a weapon, which may be fatal, rather than salutary. The alternative is too dangerous; and, while the disposition to quackery pervades every individual, from the highest ranks to the meanest, while those who claim distinction, in other sciences, arrogate it in this also, what may prove mischievous must be concealed.

SURGERY has many advantages, when compared with the practice of medicine. The objects are often before the eyes of the surgeon; the changes daily conspicuous, and show not only the state of the organ, but often of the constitution. If the object be beyond his sight, the touch will assist; and, in the most doubtful cases, the inductions are fewer, the conclusion more certain. When an operation is to be performed, as the situation of every part is known, he is ready, in every emergency; and, having obtained, by experience, a steady command of his hand, his eye, and his mind, he can meet every difficulty unruffled. Yet, as in anatomy, description cannot go far. The eye must witness the conduct of some more experienced practitioner; and operations on the dead subject must assist in giving a steadiness and a command of minute muscular exertion. As practical surgery is viewed in different lights, the directions may appear too general or too minute; but, where description could best avail, it has been most full and particular.

There is one step between the practice of medicine, and the particular remedies, too cursorily passed over by the authors on the *materia medica*, viz. the THERAPEUTICS, or those

general doctrines respecting medicines nearly related, which may facilitate our judgment in the selection. As a subdivision of the theoretical course in universities, it has not generally obtained a sufficient share of attention; in Dr. Cullen's *Materia Medica* it has had an unusual portion; but it is there subservient to his own system, and not so general in its views as the importance of the subject demands. It may be added also, that the extensive associations, usually styled classes of medicine, are too indiscriminate to direct the practice. Subordinate groups are necessary, and these, in imitation of Dr. Duncan, have been added; but the orders are in a great measure new, and are carefully connected, on one hand, with the particular remedies, and, on the other, with the indications of cure.

THE MEANS EMPLOYED FOR THE CURE OF DISEASES are either *natural* or *chemical*. By the former are meant those productions of nature which require no preparation, or only the separation of the more active from the more inert portions; chiefly the vegetable or animal substances, since there are few mineral productions which do not require some process to adapt them for use. The vegetable kingdom offers numerous remedies, of very unequal value, uncertain origin, or variously mixed and adulterated. To attain the desired purpose, or to avoid injury, it is first necessary to ascertain the real plant from which the medicinal portion is procured; a circumstance not easy, in a kingdom supposed to consist of more than 60,000 species. The investigations, however, of Linnæus himself, of his pupils Bergius, Murray, and Thunberg, have greatly facilitated the task; and the lacunæ have been, in a great measure, filled up by the labours of Sir Joseph Banks, Mutis, Loureiro, Des Fontaines, Bruce, La Marck Cavanilles, and Roxburgh. Few now remain, whose parent plant has not been accurately and scientifically distinguished. To refer, then, to the Linnæan system, especially in its most improved form, lately published by Wildenow, is sufficient to identify the plant. As, however, the system from the pen of Wildenow is uncommon, and not yet complete, a reference to the *Species Plantarum*, a work in every hand, has been preferred, and Wildenow, or later observers, have only been referred to, when it did not appear in the earlier work of Linnæus himself. No modern naturalist of credit has escaped attention in this department. The system of Linnæus is not only useful, in identifying the plant, but on account of its numerous references, to each observer who has treated of it: among the rest, to Caspar Bauhiné. This author is the link between ancient and modern naturalists; and, under the appellation which he assigns to each plant, we may discover its name in the works, not only of the ancient physicians, but of the ancient botanists, at least so far as the identity of the plant can be ascertained. It has been usual to transcribe the specific character; but, without the generic, it would be of little value, and to add, also, the synonyms of C. Bauhine would make every trifling article disproportionally long; so that the *species plantarum* is only noticed. As the botanical relations of plants are supposed to be connected with their medical powers, the natural orders have been particularly attended to.

Prejudice, superstition, and fancy, have greatly extended the list of vegetable remedies; but, in a work of this kind, though every absurdity has not a claim to considerable attention, yet the most ridiculous medicines only should be wholly omitted. There are, therefore, very few which have not shared some notice. In enumerating their virtues, it was difficult to avoid the exaggerated commendations of some authors, or the sceptical, contemptuous tone of others. In many instances, therefore, the praises of the former have been adopted, with marks of hesitation, doubt, or disbelief, sufficiently pointed; and those who have not travelled over the dreary waste of forgotten authors, would be surprised at the number of supposed properties omitted.

The animal substances are few, and their sources sufficiently known. It is sufficient, therefore, to have referred, in general, to the *Systema Naturæ*, and, in the lower orders of animated nature, to Sonnini's Continuation of Buffon's *Natural History*, or the minuter French naturalists, in the *Memoirs of the Institute*, the *Annals of the National Museum*, and the numerous tribe of monographists. Natural history has, indeed, of late, approached more nearly the confines of medicine. The latter is strictly the history of the human body and mind, in their natural and morbid state, and comparative anatomy, with its physiology, is the link which unites man to the lower orders, whose structure and whose functions are often beyond the reach of our investigation. The deficiencies are those of our knowledge; for, when this is extended, the chain is less broken, the connections more obvious. The natural history of the lower orders has, however, been little cultivated in this kingdom. It is singular that an animal, so extensively useful as the leech, has never been scientifically described in our language, except in these pages, and the *hydatis*, so common a source of disease, is by no means generally known to be an animal.

To identify the few mineral bodies which are used without preparation, we have referred to the system of the judicious and accurate Haüy, which well merits an English dress; but the greater number, which form a valuable part of the *materia medica*, require a careful, and often an operose, preparation. Medicine, in these cases, calls in CHEMISTRY to her aid; nor is the assistance confined to the mineral kingdom. It has been hinted that, in vegetable bodies, different means are employed to separate the more active from the ineter portions, often to change the form, or to concentrate their virtues. This art has been employed from the time of Galen, and has been styled *Galenical*, in opposition to *chemical*, PHARMACY; which treats of the necessary operations in preparing medicines, more strictly chemical. On the latter subject we greatly want a system co-extensive with the present state of chemical knowledge. Dr. Duncan's *New Dispensatory* is a most valuable work in this line; but as its subjects are so numerous, he is often compelled to be more concise than we could wish. The lacunæ, in this part of the subject, have therefore been filled up from the works of the latest and best chemists, particularly from that valuable collection, the *Annales de Chimie*.

The utility of chemistry, however, is not confined to the preparation of remedies. Its light has illuminated the most obscure recesses of the medical science. The nature of the animal fluids, in a state of health and disease, has been illustrated by the more refined analysis of modern chemistry, and, by its assistance in the practice of medicine, we guard against those mixtures which might weaken or destroy the virtues of the different ingredients in a formula. It may appear that this part of our subject has been expanded to an extent, which the real connection of chemistry with medicine will scarcely justify, and that chemical disquisitions occasionally trench on medical ones. In the progress of the work, in the moment of writing, the connection, however, became daily more striking; and as this, we trust, is not the ephemera of a day, it was necessary to give the younger reader every advantage of which he might, at a future period, avail himself. Till near the conclusion of these pages, there was, however, no chemical system to which we could refer. Dr. Thomson's Chemistry, a very valuable work, embraced a most extensive outline, and Dr. Aikin's Chemical Dictionary had not appeared. Neither, however, was applicable to medical inquiries, and it was necessary, not only to explain the chemical relations, but to apply them, so far as they would admit, to the principal object.

When we spoke with disrespect of the mechanical physicians, it was not with a design of depreciating the utility of NATURAL PHILOSOPHY. Though we do not calculate, with Borelli, the momentum of muscular action; with Sanctorius and Keil, the proportion of the surface of the lungs to that of the whole body; with Bellini, the acceleration or retardation of the motions of fluids, circulating through vessels passing off at different angles; yet this science will be found highly useful. The human body, though an animated machine, is constructed on the justest and most nicely balanced mechanical principles: of these the surgeon, in reducing luxations and fractures, will require a minute knowledge. The eye is a most curious optical, the ear an exquisite acoustic, machine; and the human voice, both in compass, variety, and clearness of tone, excels every musical instrument. At present, indeed, our attention is chiefly directed to the evolution and communication of heat, to the effects of the electrical and Galvanic fluids, if they really differ, and their very striking relations to that principle with whose mobility our life is most intimately connected. Indeed the relation of Galvanism to the minuter component parts of bodies has rendered it an agent of peculiar power, in the hands of the analytical inquirer; and we are indebted to Mr. Davy for one of the most important steps, in this branch of science, which has added lustre to any era. Yet all these are accessory sciences, and only of value, in the present work, so far as they assist the explanation of diseases, or direct the practice of medicine. We do not offer these volumes as a dictionary of physics, or of natural history, although they contain a larger share of each than is to be found in many works, which have been distinguished by this title. We do not offer it as a continuation of Dr. Motherby's Dictionary, which, with all its faults, has been unmercifully pillaged, without acknowledgment.

To have retained so many useless synonyms may, perhaps, require an apology. In fact, they were found in the pages of the work last mentioned, and had been introduced before its glaring defects showed that it was an unfaithful guide. Many could not be traced to an adequate authority; but it would have been improper to have rejected what others might, perhaps, find useful, and for which there might have been authorities, though we had not discovered them. Numerous, however, as they seem, more have been rejected than retained.

The references may appear, also, unreasonably numerous, and almost ostentatiously confined to foreign authors. The medical writings of our own country have not, however, been neglected; but these are, in general, within the reach of every practitioner: these only are pillaged, in every modern dictionary, while of many authors of credit the names are often unknown. We have too fastidiously arrogated exclusive merit to ourselves, and it appeared proper to point out the valuable observations of Senac, of Quarin, of Stoll, De Haen, Colin, Sarcone, &c. as well as of many Swedish and Danish physicians. Even Morgagni, as we have said, has been, of late, neglected. To lessen the extent, the Roman numbers relate to the larger portions of the work referred to—the Arabic numerals to the lesser.

In the *CURÆ POSTERIORES* many additions have been made, some of which, in the progress, had escaped attention, and others were designedly omitted, lest they might render the volumes too bulky. Various observations had also occurred in different publications and different collections since the articles were printed, and it was the author's ambition to render the work complete to the moment of publication. Somewhat may still have escaped him; but those who feel inclined to censure omissions, should look with candour on what has been done. The additions are referred to some convenient portion of the article; but they do not relate exclusively to that part, and are generally to be considered as a commentary on the whole, to avoid breaking them into too many detached parts.

To point out what is new, in these volumes, would be a tedious task: almost every article, at least every article of importance, may be styled original, scarcely in any instance copied from former authors, and usually connected with the collateral subjects. As already observed, it was designed to render the work one consistent whole, and the general principles will be found to pervade every portion; nor are the doctrines which limited the distinction of *CONCUSSIO*, forgotten under the article *ULCUS*.

Of the *PLATES* we shall add only a short account. The subjects have been chosen with great care; but the objects of the choice we must now explain. It is not necessary to say why the different *VIEWS OF THE SKELETON* have been selected: these have always formed a portion of similar representations; and, as the basis of the whole, are highly necessary. The *LIGAMENTS* have been imperfectly represented, in every English publication, and the value of

the present work is greatly enhanced by the elegant and accurate views of these connecting substances, from the superb volume of Caldani.

VIEWS OF THE MUSCLES have usually followed; but would have required many plates, without an adequate advantage. In the general practice of physic and surgery little could be gained by such representations, and we have already remarked, that it is impossible to teach the minutiae of anatomy by verbal instruction or engraved copies. If the osteology is well understood, descriptions will convey ideas sufficiently accurate for general purposes.

The course of the larger ARTERIES is of more importance, and these have been represented, with care, from the works of Haller, not separately, but as related to the adjoining parts; and they recur in different plates, which contain the lymphatics and the viscera. The volumes of Mr. Hewson, and Mr. Cruickshanks, and the elegant engravings of Mascagni, have supplied the LYMPHATICS; Loder, Haller, and Sandifort, the INTERNAL VISCERA. As the situation of these is often of considerable importance, in ascertaining the seat of a complaint, they have been represented in every view, and with great care, as the English works have been unusually deficient in this part.

The separate portions have been also supplied from the best anatomists. The elegant plates of Soemering have furnished REPRESENTATIONS OF THE EYE; Mr. C. Bell's Anatomy those of the EAR. We could not find a more accurate view of the STOMACH than in Cowper; and on again examining it, we perceive the constriction, mentioned by Mr. Home, as dividing the cardiac from the pyloric portions. Mr. Cooper has also supplied a good representation of the UNIMPREGNATED UTERUS, and its appendages; while, for the GRAVID UTERUS, and the natural situation of the FÆTUS IN UTERO, we have been indebted to the classical work of Dr. W. Hunter. Some other detached parts of less importance are represented in the plates of the arteries and the lymphatics.

A VIEW OF THE BRAIN has been supplied by Loder; and, when we reflected that, in very few circumstances, the course of the different nerves, in their progress, was of importance, and that, in these, the minute accuracy, acquired only by dissection, was requisite, we avoided enhancing the price of our work, by plates not generally useful. The SURGICAL INSTRUMENTS represented are those most commonly employed, in the more improved practice of the art.

# A NEW MEDICAL DICTIONARY.

---

## A B A

**A**. The letter a, with a line above it, thus, *ā*, is used in medical prescriptions for *ana*, of each; sometimes it is written thus, *āā*; e. gr. *℞* Mel. sacchar. et man. *ā* vel *āā*, *℥j*. i. e. Take of honey, sugar, and manna, of each one ounce.

*A*, in composition, implies a negative, as in *A'CHYLUS*—from *α* priv. and *χυλος*, *chylus*—deficient in chyle.

*A'AVORA*, a species of palm found in Africa, and the American Islands. The nucleus of the fruit resembles an almond; it is mild and nutritious, and is used by the natives as an astringent, particularly in cases of diarrhœa. The parenchyma which surrounds the kernel is eaten by cows and other animals: by maceration it affords an oil which is used as a condiment, and to burn. The plant is figured in La Marck's Illustrations of Natural History, Pl. 896, but has not been arranged in the botanical systems. It has been transplanted to Guiana, and often confounded with the cocoa-nut tree.

*A'BACTUS*, (*driven away*.) It is applied to abortions, procured by medicine.

*A'BACUS*, (from a Hebrew word *ABAK*, *dust*.) A table used for preparations; so named, because mathematicians used to draw their figures on tables sprinkled with dust. It generally means an instrument very anciently employed to facilitate arithmetical operations.

*A'BACUS MAJOR*. A trough used in the mines, wherein the ore is washed.

*ABALIENA'TUS*, *corrupted*. Celsus. In English, we use only the word *alienated*, which is applied to injuries of the mental powers.

*A'BANET*. See *BANDAGE*.

*A'BANGA*. See *ADY*.

*ABAPT'ISTON*, or *ABAPTISTA*, (from *α* priv. and *βαπτίζω*, *immergo*, to sink under.) The perforating part and shoulder of the instrument called a *TREPAN*, to prevent its sinking suddenly upon the membranes of the brain, when the operator perforates the skull: the present practice renders this precaution need-

VOL. I.

## A B D

less, by having substituted a much more manageable instrument. See *TREPANUM*.

*ABAR'TAMEN*. See *PLUMBUM*.

*ABARTICUL'ATIO*, (from *ab*, and *articulus*, a joint.) See *DIARTHROSIS*.

*A'BAS*. Dr. Turton has made *A'bas* a synonyme with *Tænia*, or Tape-worm; a mistake, we presume, for *Tinea*, the Moth-worm. See *Castelli Lexicon Medicum*. See *TINEA*—*ACHOR*—*EPILEPSIA*.

*ABA'SIR*. See *SPIDIUM ARABUM*.

*ABBA'ISSEUR*, a term given by Winslow to one of the muscles of the eye, depressor oculi of Albinus.

*ABD'OMEN*, the *BELLY*, from *abdo*, to hide; as its contents lie hid in it. The last syllable is only a termination; as from *lego*, *legumen*. It is also called *Imus Venter*. *Abvus*. *Gaster*. *Katocelia*. Fæsius calls it *Dertron*; *Nedys*; and the viscera contained within, *Nedya*.

The body is generally divided into three cavities, called, by anatomists, *venters*: viz. the head, or *upper venter*; the breast, or *middle venter*; and the abdomen, or *lower venter*.

The belly is divided, on its outer surface, into four regions, called the *epigastric*, the *umbilical*, the *hypogastric*, and the *lumbar*. See *EPIGASTRIUM*, *UMBILICALIS REGIO*, *HYPOGASTRIUM*, and *LUMBARIS REGIO*. These are all contained betwixt the circumference of the false ribs, and the bottom of the *ossa innominata*.

The belly is separated from the breast externally, by the extremities of the ribs, and internally by the diaphragm; and it is terminated below by the *musculi levatores ani*.

The bottom of the belly, named *Neiera*, on its fore part, is called the *puenda*; and on its back part, the buttocks, and anus; and underneath, betwixt the anus and the pubes, the *perinæum*; indeed, the name of *perinæum* is given to the whole space from the *os coccygis*: that part which lies between the anus and pubes is distinguished, according to Dr. Hunter, by the term

B

fore perinæum, and that from the coccyx to the anus the hind or back perinæum.

The cavity of the belly, formed by the above-named parts, all which are covered with the *membrana adiposa* and the skin, is lined on the inside by the peritonæum. This cavity contains the stomach, intestines, mesentery, mesocolon, liver, gall-bladder, spleen, pancreas, glands of the mesentery, *vasa lactea*, receptaculum chyli, kidneys, renal glands, ureters, bladder, and the internal parts of generation.

Though we have employed common language, in the expression of the cavity of the belly, in reality there is no cavity. The peritonæum may be compared to a flaccid bladder, behind and on the outside of which the intestines and other supposed contents are placed. This membrane is then folded around them, and the two sides of the bladder, after enfolding the intestines, are brought together, forming the mesentery: within these folds of the mesentery the lacteals pass towards the blood vessels. The peritonæum is therefore contiguous on its internal surfaces, or only separated by a vapour called an *halitus*, which, after death, condenses into a watery fluid; this fluid in drops is greatly augmented, and is said by the more correct authors to be contained in the cavity of the *peritonæum*.

The principal arteries of the belly are, the *epigastric*, which are the lowest portion of the internal mammary artery, the *inferior aorta*, the *celiac*, the *upper mesenteric*, the *hemorrhoidal artery*, the *renal*, called *emulgent*, the *spermatic artery*, the *lower mesenteric artery*, the *lumbar*, the *iliac*, the *lower epigastric arteries*, and the *pubicæ*.

The principal nerves of the belly are, the stomachic, formed by the extremity of the eighth pair; the lower portion of the great sympathetic nerves, the two semi-lunar or plexiform ganglions, the hepatic, splenic, renal, upper and lower mesenteric plexus, the nerves of the loins and sacrum, also the origin of the crural and sciatic nerves.

The appendix ensiformis, the lower pointed extremity of the sternum, the cartilaginous portions of the last pair of true ribs, those of the first four pairs of false ribs, all the fifth pair, the five lumbar vertebræ, the *ossa inominata*, the *os sacrum*, the *os coccygis*, form the bony sides of the cavity of the belly.

The diaphragm, the muscles called, particularly, *musculi abdominis*, the *quadrati lumborum*, the *psoæ*, the *iliaci*, the muscles of the coccyx, and of the *intestinum rectum*, form the greatest part of the circumference of this cavity. As auxiliary parts, some portions of the *sacro lumbares*, *longissimi dorsi*, &c. might be added.

The muscles belonging to the belly are five pair; viz. the *obliqui externi*, the *obliqui interni*, the *transversales*, the *recti*, and the *pyramidales*. Their action is necessary to expiration, as they pull down the thorax, and they are very useful in efforts to speak loud: they assist also in the expulsion of the *fæces* and urine. Some people, who find a difficulty in going to stool, or have a suppression of urine, are said to relieve themselves by pressing the abdomen with their hand: the expulsion of the *fœtus* also is greatly assisted by the abdominal muscles. Mr. Pott was of this opinion. He said, that he had seen a child, which lived nearly three weeks,

though it had no abdominal muscles; that this child could not either propel or expel the *fæces* nor urine perfectly, without artificial aid. Mr. Haighton also found that the most violent stimuli, when applied to the stomach either externally or internally, were in his experiments insufficient to produce an evacuation of its contents, without the concurring efforts of the diaphragm, and muscles of the abdomen.

There is a sinus on each side of the *cartilago xiphoïdes*, between the *transversalis* and *recti* muscles, into which, on the left side, the stomach is sometimes pushed by violent vomiting; a disease called *GASTROCELE*. This tumor is in the upper part of the *linea alba*. The disorder is attended with excessive pain, which is greater when the person is up, and gradually goes off when he lies in a horizontal posture, a circumstance which distinguishes the disease. There is a continual vomiting; every thing taken in is immediately rejected; and hence succeeds an atrophy. All hernias of the *linea alba* require the same management; but this of the stomach demands particular attention. They are easily reduced, and should be kept up by a truss: if the rupture does not recede, the stricture must be enlarged and reduced in the same manner as in other ruptures. Happily this case is very rare; when it occurs, little more can be done than to alleviate general symptoms: if it cannot be returned by the hand, any operation will be a doubtful aid, as inflammation soon comes on, and the admission of air into the cavity of the abdomen immediately increases it.

Pain and other disorders of the belly sometimes happen from keeping it too cool. The circulation of the blood from the viscera in the belly, by the *vena portæ* to the liver, and afterwards in the liver, is greatly promoted by the alternate compression, which the contents of the belly receive from its muscles and the diaphragm: and it is of service in dissecting living animals, that, when the viscera of the belly are exposed to the air, this circulation of the blood towards the liver, by the *portæ*, is much impeded, or totally stopped. Hence it follows, that in proportion as the action of the muscles of the belly is impaired, and the cavity laid open, this circulation, so necessary to the animal economy, must be obstructed.

The muscles of the belly and peritonæum are subject to inflammations, which have been mistaken for inflammation in the liver or the intestines: to distinguish them, see *HEPATITIS*; *INFLAMMATIO MUSCULORUM ABDOMINIS*, et *PERITONITIS*.

The rheumatism sometimes affects the muscles of the belly, which has been mistaken for a colic, or for an inflammation of some of the viscera within: in this case, however, the usual symptoms of inflamed viscera are absent, and the medicines which are useful in the colic are without effect in this complaint.

For the management of wounds in the belly, see the article *VULNUS*.

**ABDO'MINAL Ring.** An opening in the abdomen, formed by the tendinous fibres of the external oblique near the *os pubis*, through which the round ligaments of the uterus, and the spermatic vessels in the other sex, pass. Through this ring portions of the intestine sometimes come down, forming ruptures. See *HERNIA*.

**ABDUCE'NTES NERVI**, part of the sixth pair; so

called because they are lost on the abductores oculi.

**ABDU'CTIO**, (from *ab* and *duco*, to draw,) a species of fracture, when a bone near the joint is so divided transversely, that the extremities recede from each other. Cælius Aurelianus uses this word for a strain. Abductio properly signifies leading from or drawing away, and it is from the action of the muscles that the divided ends of fractured bones recede. *Abruptio* is used in the same sense, as are also *Apoclasma*, and *Apagma*.

**ABDU'CTOR**, (from *abducere*, to draw from.) Those muscles are called abductors which draw backwards the moveable parts into which they are inserted; of which there are several in the human body, viz.

1. **ABDUCTOR AURIS**, called also *triceps auris*, and *retrahens auriculam*, *bicaudalis muscularis*, *intricatus musculus*, *detractor auris*; a muscle of the external ear, called by Winslow the *posterior musculus auris*. It is called *triceps*, because it has sometimes three beginnings. It is composed of a few fleshy fibres, which arise from the superior and fore part of the apophysis mastoideus, and descend obliquely to their insertion, in the middle of the concha auriculæ. It covers the posterior ligament. Dr. Hunter thinks the ear has only two muscles belonging to its external parts that the *retrahens auriculam* arises from the mammillary process of the temporal bone, and is inserted into the lower external part of the ear, to pull it backward.

2. **ABDUCTOR DIGITI MINIMI MANUS**. Riolan calls it *kypothénar*. It rises from the os pisiforme of the carpus, runs upward on the inside of the hand, and is inserted into the external side of the little finger, or its first joint. It helps to separate the little finger from the rest, and also to bend it. It is the *flexor parvus minimi digiti* of Albinus.

3. **ABDUCTOR DIGITI MINIMI PEDIS**. It rises fleshy and tendinous from the semicircular edge of a cavity on the outside of the inferior protuberance of the os calcis; it has another tendinous beginning from the os cuboides, and a third from the upper part of the os metatarsi minimi digiti. It is inserted into the upper part of the first bone of the little toe externally and laterally. It draws the little toe outwards from that next to it.

4. **ABDUCTOR INDICIS**. It arises fleshy by two heads from the metacarpal bone of the fore finger, and the first bone of the thumb, and is inserted by its tendon into the basis, or first joint of the fore-finger, laterally next the thumb. It brings the fore-finger from the middle-finger, and near to the thumb. Cowper calls it *adductor pollicis*. Douglas says, its use is to bring the index towards the thumb; whence, in respect of this, it may be styled *adductor*; and, in respect of that, *abductor*.

5. **ABDUCTOR OCULI**, called also *indignatorius*, or the scornful muscle; *musculus exterior*; also, *abducens*, *iracundus*, and *rectus externus*. It rises tendinous and fleshy from the foramen lacerum, without the orbit. It is inserted by a thin tendon into the sclerotis, on that side next the nose. It moves the eye towards the little angle.

6. **ABDUCTOR POLLICIS MANUS**, called also *thenar* by Riolan; and *abductor brevis pollicis manus*, by Albinus. It rises by a broad, tendinous, and fleshy be-

ginning, from the inner part of the transversa ligament of the carpus, and from one of its bones which articulates with the thumb, and is inserted tendinous into the second joint of the thumb. It draws the thumb from the fingers.

7. **ABDUCTOR POLLICIS PEDIS**, called also *thenar*. It rises fleshy from the inside of the os calcis, and tendinous from the os naviculare, and forms a strong tendon, which is inserted at the inner part of the first bone of the great toe, upon its sesamoid bone. It pulls the great toe from the rest. It often has a tendinous origin from the edge of the os cymbiforme, receiving near this bone some tendinous filaments from the tibialis anticus. These two muscles, No. 6, 7, are called *Thenar*, because they make part of the *Thenar*.

**ABELICE'A**, (from *α* priv. and *βελος*, a dart; i. e. without thorns.) See **BRASILIIUM LIGNUM**.

**ABELMO'SCHUS**. (*A-bel-mosch*, ARAB. or *Granum Moschi Rumph.* *hirsuta Margr.* Brazil, *Moschus Arabum*. Also, *Alcea Indica*, *Alcea*, *Abrette*.) The seed of a plant which has the flavour of musk, called the MUSK MALLOW. The plant is the *HIBISCUS ABEL-MOSCHUS* Lin. Sp. Pl. 980, indigenous in Ægypt, and many parts of both the Indies. The seeds are flat, kidney-shaped, the size of a pin-head, grey or brownish without, and white within. They are very fragrant, and their scent is like a mixture of amber and of musk; to the taste they are of a slightish aromatic bitter. The Arabs mix them with their coffee; though their chief use is as a perfume; but, from their peculiar flavour, as well as other sensible qualities, they seem to merit more attention than has hitherto been paid to them as a medicinal substance. The best comes from Martinico. Those which appear new, plump, dry, and well scented, are preferable.

**ABERRA'TIO**, (from *aberro*, to wander.) In medical writings it expresses Nature's deviating from her usual progress. *A Lusur Naturæ*. See also **LUXATIO**.

**ABE'SAMUM**, DIRT or CLAY.

**ABE'SSI**. See **REBIS**.

**ABEVACU'ATIO**, or **ABVACUATIO**, (from *ab* dim, and *evacuo*, to pour out,) a partial or incomplete evacuation of the faulty humours, whether by nature or art, called *Apocenos*, partial fluxes, as watery eye, gonorrhœa, &c.

**A'BHEL**, one of the appellations of savine. Q. V.

**A'BIES**, (probably from *απιος*, a wild pear, the fruit of which the cones of the fir resemble.) **FIR**, called also *Elate Theleia*.

The fir-tree is an evergreen, and coniferous, with numerous, narrow, stiff leaves, standing solitary, or unconnected at their bases with one another.

Six species afford materials for medical use. Linæus includes the *abies* in the genus of *pinus*.

1. **ABIES**, *Pinus sylvestris* Lin. Sp. Pl. 1418.

2. **ABIES**, the YEW-LEAVED or SILVER FIR. *Pinus alba* Lin. Sp. Pl. 1418.

These two species are natives of the northern regions; the second grows on dry mountainous places; the first in lower and moister grounds. Norway, Switzerland, and some parts of Germany, afford great quantities of them. They are indigenous in some parts of Britain; but are chiefly to be met with in plantations. The branches, and the fruit gathered in autumn, abound

with resinous matter, and yield, on distillation, an essential oil, and a liquor impregnated with a peculiar acid, called ACIDUM ABIETIS; and, when added to water, is thought to communicate to it both the flavour and other properties of tar-water. This acid resembles the acetous, differing only by the addition of the turpentine which comes over with it; and the famous tar-water was not very different: it contained only a larger portion of the essential oil. This acid and the tar-water have produced good effects in some obstinate coughs, particularly in that chronic catarrh which is benefited by warm diuretics. Decoctions of the wood and tops promote perspiration and urine; are sometimes useful in rheumatic cases; and been considered as serviceable in healing internal ulcerations, particularly of the urinary passages. They are injurious if any fever attends; but may be useful where the circulation of the fluids is too languid.

3. ABIES CANADENSIS, *vel* VIRGINIANA, the CANADA or VIRGINIA FIR; *pinus Canadensis* of Linnæus, Sp. Pl. 1421.

4. ABIES BALSAMEA, BALM OF GILEAD FIR; so called from the fragrance of the leaves when rubbed. PINUS PINES Lin. 1418. PINUS LARIX Lin. 1420. It is the *pinus balsamea* of Linnæus, 1421.

All the parts of these trees contain a bitterish, pungent, essential oil, which by exposure to the air becomes a resin: turpentine is obtained by making incisions in their trunks at a proper season. For the different kinds of turpentine, see TEREBINTHINA.

The common red fir affords the greatest quantity of turpentine; and from the turpentine is obtained white resin, see RESINA; tar, see PIX LIQUIDA; pitch, see PIX NIGRA; and Burgundy pitch, see PIX BURGUNDICA.

The silver fir produces the Strasburg turpentine; it is far more grateful than the common sort, and called liquid resin, to distinguish it from the dry resin, which resembles frankincense.

From the Canada fir is obtained a still finer and more grateful turpentine, called *Bals. Canadense*; it is discharged, during the summer heats, through incisions made in the trees, transparent, and almost colourless. It is a good substitute for the bals. capivi. See CAPIVI BALSAMUM.

The balm of Gilead fir emits from its cones in large quantities a turpentine with a fragrance resembling the balm of Gilead. Spirit of wine extracts a resin both from the cones and the leaves of a similar quality. See BALSAMUM.

Rectified spirit of wine, digested on fir, extracts all its active parts, with some of its mucilage. The cones of all the sorts yield the most agreeable tincture.

Water dissolves a portion of the oil by the assistance of the gum combined with it. The wood and the cones are taken at the latter end of Autumn, for their oil; and in distillation with water a large quantity of essential oil arises. The oil drawn from the wood is nearly similar to the oil of turpentine. That obtained from the fresh cones is superior in subtilty and fragrance to all the oils of turpentine usually met with. NEUMANN.

The tops and the cones of the fir-tree are moderately warm, promote perspiration, and increase the discharge by urine. Four ounces of the fresh tops are put to a gallon of diet-drink. Fermented with beer,

they impart to it a very salutary warmth, highly useful in cutaneous complaints, scurvy, &c.

A spirit distilled from the young leaves is a succedaneum for the aq. Hungarica.

The *Ess. Abietis Pharmacop. August.* is the balsam of the fir-tree, joined with scurvy-grass: the fir-cones, while young, tender, and of a red colour, are bruised and digested two days in four times their quantity of spirit of scurvy-grass, then the tincture is pressed out.

The tops and leaves of the silver fir are used in making BRUNSWICK MUM.

A'BIES CEMBRA, Lin. 1419, affords the *balsam of Libanus*, or the *Carpathian balsam*.

A'BIES MUNGHOS SCOPOLI, an alpine tree of Hungary, which produces the *oleum templinum*, or *Krumholze oil*.

ABIETA'NUM OLEUM. See TEREBINTHINA ARGENTORATENSIS.

A'BIGA HERBA, *chamæphytis*, or ground-pine. It is probably so called from *abigo*, to *expel*, as it is said to promote delivery. Blancard thinks its name is derived from its leaves resembling those of the abies.

ABLACTA'TIO, (from *a priv.* and *lacto*, to *suckle*.)

ABLACTATION, or WEANING a child from the breast. Also called *Apogalactismus*. When the mother wants health, or strength; is affected with any constitutional disease, or the milk is in small quantity; has too small nipples, or ill-formed ones; when the infant will not take the breast;—it is adviseable to wean the child; indeed, often absolutely necessary. It can never be useful to continue the breast more than eight or nine months; but generally, if a child is favoured with a good supply by sucking, during its first three or four months, and is healthy, it will rarely be the worse for weaning at a more early period. If it feeds well with the spoon, and is free from disorders in its bowels, a tendency to convulsions, &c. weaning may be attempted at any time. But, if the child refuses to feed; or, though the diet be changed to gravy and beef tea, the bowels should be disordered, another nurse should be sought for, and weaning must be deferred until more favourable circumstances attend. In general, the sooner a child is weaned, the more easily it parts with the breast. Prudence directs to accustom a child to early feeding with the spoon, and to continue it until the breast may be wholly omitted. In general, children should be fed during the first months three or four times a day; and, if not suckled in the night, once at least, if not twice, during that period. Suckling in the night should, if possible, be avoided; for the mother, especially in the higher ranks of life, wants some hours of respite. If the child is early brought to regular hours of feeding, it will soon give little trouble.

The food should be simple and light; without wine, or spices. Well fermented bread, baked hard, and reduced to powder, will make a proper food, when boiled smooth in water. Should the stomach be flatulent, a few caraway seeds may be added. If this food turn sour, beef or mutton tea (prepared by infusion only) may be occasionally substituted, or a little beef gravy may be given. A child will in feeding always first endeavour to drink. He may be allowed to do so with moderation. A little time should be suffered to elapse, and the soaked bread should then be offered. If refused, he may drink again, but in less quantity; and

should he still refuse the bread, it is a sign that he does not require any solid food. In feeding, he should be in a sitting posture, or, if recumbent, should be occasionally raised, gently moved, and amused. After feeding, he will soon sleep; but a child should never be awakened, unless the sleep be uneasy or morbidly continued.—Moss, CADOGAN, and ARMSTRONG. See TEETHING.

ABLE'PSIA, ABLEPSY, ( $\alpha$  priv. and  $\beta\lambda\epsilon\pi\omega$ , *video*.) Blindness, want of sight, rashness, indiscretion.

ABLU'ENTIA MEDICAMENTA, (from *abluo*, to wash off.) Medicines suited to wash off from the external or internal surfaces of the body any matters improperly adhering to them.

ABLU'TIO, (from *abluo*, to wash away,) ABLUTION. A washing or cleansing either of the body or intestines. In chemistry, it signifies the purifying of a body by repeated effusions of a proper liquor: this is done various ways, by cohobation, circulation, &c. See COHOBATIO.

ABO'MASUM, (from *ab*, dim. and *omasum*, the stomach of a beast.) The name of the fourth stomach of a beast that chews the cud. The first is called *venter*, or rather *ventriculus*, the word used for it in Aristotle being  $\chi\omicron\iota\lambda\iota\alpha$ ; the second *reticulum*, or *cecryphalos*; the third *omasum*, or *omasus*; the fourth *enystroon*, the same as *abomasum*, which completes the digestion, according to GORRÆUS. ARISTOTLE says it is the second ventricle, or thick part of the stomach of ruminating animals, in which the food is concocted.

ABO'RTUS, ABO'RSUS, ABO'RTIO; (from *ab*, defect, and *orior*, to arise.) Aboriri quasi intempestive oriri. ABORTION or MISCARRIAGE. The birth of a child before its due time; or, the destroying a child in the womb: termed also *convulsio uteri*, *deperditio*, *diaphthora*, *ectrosis*, *exambloma*, *examblosis*, *amblosis*, *apophallesis*, *apophalsis*, *apophthora*.

Miscarriages happen at any period of pregnancy, and from innumerable causes; most frequently in the third and beginning of the fourth month: but those which happen in the sixth, or later, are more difficult and dangerous.

Women who are very fat, who have miscarried before, and who easily or without any particular inconvenience, during the time of miscarriage, or soon after, part with their burden, are most subject to this accident.

The causes are various; *violent emotions*, *frights*, *passions*, *violent purges*, *immoderate exercise*, particularly in riding or dancing, an *obstinate diarrhœa*, the *small-pox*, and other acute diseases; *too much blood*, *great loss of blood*, and not unfrequently an *incautious use of the lancet*. See Dr. Wallis's Essay on Injudicious Bleeding in Pregnancy. Habitual miscarriages happening at stated periods, without manifest cause, are very common among women of fashion, from the more general causes of weakness, viz. *indolence*, *sitting up late at night*, *fear*, *grief*, &c. In general, the causes may be reduced to what immediately affects the child, the placenta, the membranes, or the mother. Thus, the death of the child; membranes too weak; the funis too short; the placenta separated or diseased, are causes of abortion.

As to the mother, besides the causes above enumerated, the two following are very common ones. The first is *too great a stricture of the uterus*; in which case it is not capable of a dilatation sufficient to make room

for the fœtus as it increases in bulk: this is known by *violent pains*, *a great tension and hardness of the belly*. Bleeding, and whatever relaxes, are indicated in this case. The second is a *relaxation of the uterus*, which renders it unable to support the inosculation of the vessels of the placenta into itself, after the fœtus and placenta, &c. are grown to a certain weight; and of all others, this is the most frequent. In these two cases, the miscarriage always happens about a stated time of the woman's pregnancy.

An approaching miscarriage, or the death of the child, is to be apprehended by the *breasts growing suddenly flabby*; *a painful weight in the loins*, which reaches to the thighs; *pains about the navel, head, and eyes*; *coldness in the extremities*: when violent means have been used to expel the fœtus, *convulsions occasionally come on*; *pains in the belly*, like a cholick, and sometimes more like labour pains; *shiverings*; *fainting*; and after the time of quickening, *the motion of the fœtus is more languid, and less frequent than usual*: as the miscarriage draws nearer, *the pains of the loins increase, extending to the hips*; *the orifice of the womb begins to be dilated*; *a watery discharge is perceived, which becomes bloody*; at length blood, pure or clotted, comes away. The most certain sign is THE DISCHARGE OF A FLESH-COLOURED FLAKY SUBSTANCE, WHICH COMES AWAY WITH THE WATERS; this is the tunica decidua, or spongy chorion; and when it peels off from the womb, and appears with the waters, a miscarriage is unavoidable.

Healthy women, who have naturally a loose belly, a moist uterus, and have brought forth large infants with easy labour, who are lean, but not very sanguine, bear miscarriages more easily; but in general, they are ever to be considered as more dangerous than natural labours; for more violence is necessary to discharge the imperfect fœtus than when it has arrived at its full maturity; the placenta is also more firmly attached during the growth of the fœtus than when it is full grown; and besides the danger of a fatal hæmorrhage from the adhesion of the placenta, the os tincæ does not so easily dilate before the full period of gestation. If a part of the placenta is separated before the burden is delivered, the uterus cannot contract sufficiently to close the bleeding vessels. These hæmorrhages are extremely dangerous, and often fatal.

In constitutions subject to this misfortune, be careful to avoid whatever has been formerly suspected to cause it, and also guard against every known cause that may possibly endanger the patient. In the first months keep the belly gently open with laxatives; and avoid all exertions, even the most moderate. If violent pains come on, at the third month, in a robust habit, some blood may be taken; and if symptoms of plethora should be strong, this may be done, though nervous weakness may be otherwise evident.

If pains come on after bleeding, *tinct. opii camphorata*, or *tinct. opii cum infus. cinchonæ*, is necessary.

In very relaxed habits, the bark is useful; but in general, the tincture of opium, or the pulvis opiatum with nitre, are the best remedies. The bowels must however be kept open with castor oil or moderate doses of salts; and should a tenesmus keep up local irritation, it may be quieted by an opiate or a starch clyster with from 80 to 100 drops of the tinctur. opii. Rest.

with opiates, cool drinks, gentle laxatives, and moderate but not violent astringents, are the best remedies. Should miscarriage be connected with any other general disease, this must be the chief object of attention.

As precautions to prevent miscarriages during pregnancy are not so efficacious as those used betwixt a miscarriage and the next impregnation, the advantage of this interval should be embraced, the particular disorders should be attended to and removed, and the general vigour restored so far as possible: to this end cold-bathing will greatly contribute, if it is used near bed-time, or after the dinner is well digested. The chalybeate waters are excellent in this case; they should be drank at the spring, early in the morning, to the quantity of three or four half pints; their use must be continued two or three months, and exercise within the strength should be used at the same time.

*Lime-water* has been supposed to be singularly useful both in curing a disposition to, and preventing threatened miscarriages, in those who have often miscarried before. If in these cases the water was made fresh when used, and drank before the heat excited by the ebullition on quenching the lime was gone off, the efficacy has been thought to be the greater. This plan, however, wants the sanction of extensive experience.

*Convulsions* and *Floodings* coming on pregnant women demand immediate help from art, to extricate the fœtus from the womb; and though properly belonging to the article of midwifery, yet very naturally fall under this of *Abortion*. These cases admit of no delay. Labour must be brought on, and the child turned, if necessary.

A cure is uncertain when convulsions come on in time of labour, except you can deliver the child; and as in some cases delivery is impracticable, on account of the length of the neck of the womb, if the woman cannot be relieved by medicines, death must inevitably be the consequence. If then the convulsions come on in the beginning of labour, bleed freely, and repeat the operation according to the strength of the woman and the violence of the disease. Empty the bowels with a clyster; if time admits, apply a blister on the nape of the neck and on the extremities. If the fits go soon off, if in the intervals the senses are entire, and there is no fever, wait the event; but if there is vomiting, the pulse be low, the patient comatose, the child must be taken off. If the patient is convulsed three, four, or five hours together, foams at the mouth, and the pulse is disordered, delivery must be hastened.

If convulsions come on after the labour is in some measure advanced, they will have the same effect as labour-pains, and the child will be delivered by them. If they have not this effect, if the head of the child is low enough for the forceps, these may be employed. If not, by giving opiates largely by the mouth, or by clyster, dashing cold water in the face, according to the plan of Denman, or giving the fox-glove, as recommended by Dr. Hamilton, the convulsions may be checked till weakness occasions the dilatation of the os tincæ.

After labour comes on, the convulsions lessen, and during every pain cease; which shows that the irritation is on some of the nerves above the os internum. They rarely continue after delivery, and a large opiate, with a mild nourishing diet, is only requisite. They

sometimes come on after delivery; either from the irritation of after-pains or some other cause. In these cases, the bowels must be emptied by a clyster, and opium given freely either by the rectum or the mouth. Convulsions, after delivery, are seldom fatal: before delivery, about six or seven in ten will elude the most active and best concerted measures.

*Floodings.*] Floodings happening to pregnant women are very different in their effects, so are as differently to be regarded. Pregnant women have the menses sometimes to the last; but they are pale, thin, and do no harm. Those floodings which do not require delivery come on gradually, but generally with the usual pains of menstruation: they are not continual; and, with due care, they cease. Those which cause miscarriage or death, appear suddenly, and in large quantities; they flow with slight occasional intermissions only. In the first case, the os tincæ is not affected; in the latter it opens.

In the early months, the causes are, violent shocks, sudden or great frights, &c.; but in the latter months, the separation of the placenta, in whole or in part, is always the cause: the uterine arteries pour their blood into the cellular part of the placenta; hence, when any of these cells are torn, all the blood carried by them must be discharged by the os internum. The placenta adhering to the os internum may be the cause of flooding; in which case the discharge increases as the os internum dilates.

The signs of an approaching flooding are, *restless pains like labour, pain in the eye-balls, troublesome dreams*: if the flooding is internal, *the os tincæ will be stopp'd with clotted blood, the belly will swell, the pulse fail and flutter, and faintness, with giddiness, come on*. Floodings are more or less dangerous, according as pregnancy is advanced, because the diameters of the vessels are proportionably enlarged. Flooding preceding delivery is, for the most part, followed with a dead child: and, generally, a flooding in the first months is followed by a miscarriage.

*If the flooding threatens speedy danger*, attempt nothing till the patient's friends are apprised of it, and insist on your endeavours. It is seldom that any manual assistance is given in the first five months, for till this time the os tincæ is but little altered, and indeed the pregnancy is often somewhat uncertain; but afterwards the os tincæ opens, so that the fœtus can be brought away by force. In the latter months, if a flooding comes on, if at the same time the pulse is tolerably firm, the colour remains, the loss of blood not very considerable, and if no pains which will assist delivery come on, we must wait their effects. If the discharge abates on the rupture of the membranes, pains come on, and all seems well, a little patience is only necessary; but, if the flooding continues, if the pulse is low and unequal, if the strength fails, the face grows pale, fainting and cold sweats come on, the delivery must be hastened as fast as can be done with safety.

*If death is not so near*, take as much time as symptoms will permit: if the flooding is just come on, the strength and spirits not yet failing, the os tincæ will be softened by the continued discharge; it will more easily dilate, and the birth will be less difficult. A little delay will be consequently advantageous.

*If the violence of the symptoms demand immediate help*,

proceed without waiting for pains, for they seldom return after the flooding is so violent as to cause fainting or convulsions; nor must we wait for a considerable dilatation of the os tinea, which without pains is not to be expected: indeed the pains are the less necessary, as the hæmorrhage assists in relaxing it.

*If flooding happens during the first six months*, bleed according to the state of the pulse, keep the patient still in bed; and though she is faint, cold, or low, give no warm cordials, for they increase the discharge in proportion as they raise the spirits. If a vomiting attends, the neutral mixture, and such light food as passes soon into the circulation, such as broths, salep, milk, &c. may be given in very small quantities, lest vomiting should be excited; but let the supplies be frequent. Relieve costiveness by clysters that are barely laxative. If anxiety and wakefulness are distressing, let opiates be repeated, at due distances, in small doses. The bark joined with opiates, and sometimes with nitre, is very effectual. The pulv. stypt. Ph. Ed. above named, is also not to be omitted; and cloths dipped in cold water may be applied to the region of the uterus.

*If this disaster happens in the seventh or eighth month*, the danger is far greater than in the former months; for the diameter of the vessels is enlarged, and the neck of the uterus is rigid; so that if the flooding is violent, the woman may be lost before the best helps can be of any use. In this case, as in the former months, it is the best not to attempt delivery till a laxity of the parts is come on; for were we to attempt it in their rigid state, we should increase the flooding, tire ourselves, and exhaust the woman, and this without being able to deliver her.

*The most dangerous time is the last month of pregnancy*, for then the diameters of the vessels are at their greatest dimensions. If in this case the blood runs off in a full stream, introduce the hand, break the membranes, and, taking the advantage of the waters, turn the child, and bring it footing. If at this period a flooding happens, or in the time of labour, and the patient loses not a great quantity in a short space of time, she may bear it, and in the course of labour-pains it will stop, and the labour go on well. If the woman is plethoric, and not much weakened by the discharge, if the child presents fair, break the membranes to restrain it, and allow time for the labour to come on afterwards.

*If, during labour, a flooding is caused by a laceration of the placenta in delivering the first of twins*, immediately introduce the hand, turn the remaining child, and bring it away by the feet; then the uterus will contract, and the diameters of the vessels will be lessened: but if the flooding precedes the delivery of a twin, and then abates, let the other remain a little, and recruit the woman with caudle or jelly; for in twin cases the belly is vastly distended, and the vessels are very much dilated and full, and a sudden emptying of them may cause a syncope, or even death.

The placenta is not only sometimes loose, but also is sometimes fixed over the os tinea, in which case delivery must be effected with all convenient speed. To deliver with safety when thus circumstanced, introduce one finger into the os tinea; then two, and gradually the rest, until the whole hand is introduced; dilate the parts by degrees; then, if the membranes first offer,

break them, and get the feet of the child, by which bring it away, and deliver the rest at discretion. But if the placenta presents at the os uteri; 1st, you will know by the touch; for, on introducing the finger, neither the membrane nor the naked head is perceived; on the contrary, thick and soft flesh is felt, distinguished from that of a child by being softer, and also without form. 2dly, This case is always joined with a flux of blood, to the danger of both the mother and the child; therefore the birth must be hastened without waiting for pains; a finger must be introduced into the os tinea, and the placenta removed until the membranes can be reached; which done, tear them to come at the feet of the child: if you cannot push the placenta from the os tinea, force your finger through its middle, and make way by dilating your fingers for the membranes to descend; this done, break them, and, by the running off of the waters, the uterus will contract, and gradually lessen the flooding: if, on the waters being discharged, the head presents, endeavour to remove the placenta, so as to give way to the head, then the pains may bring forth the child; but if it is in a preternatural posture, bring it away by the feet.

*If the flooding happens from a blow, and there is a great discharge in a little time*, delivery must be hastened as speedily as possible; and if the hæmorrhage abates not on the child being brought away, the placenta must be hastened too. Remember, that during delivery an assistant should gently press the belly of the woman, and continue the pressure a little while after the placenta is delivered; the woman must be supported by frequent small quantities of caudle.

The floodings which happen after delivery are sometimes very dangerous; this kind is generally owing to the womb being suddenly emptied, and so not having time to contract the diameters of the vessels, they remain open, and the blood by its own specific gravity pours out. The chief intention here is to contract the uterus: to which end the properest means is the application of cloths dipt in vinegar, or vinegar and water: these should be laid on the back and region of the womb. Also stupes impregnated with a mixture of cold water and vinegar, or cold water alone, and passed up the vagina to the os tinea, have been recommended. A hand may be placed on the belly, to press the uterus towards the pubes. *But the greatest specific in this case is an opiate: it should be given in large doses; for if the woman can be once composed, if it be but for a few minutes, the flooding will almost certainly cease; and when it once ceases, it rarely returns.*

To deliver a woman without pains, or to force labour, the subsequent directions should be pursued: lay her on her back, with her heels upon the bed, having assistants to keep her steady. The operator may be in any position that he finds most convenient; in the course of one labour he will generally find occasion to sit, stand, and kneel; the elbow of the introduced arm should be supported by the knee, to give additional strength, and to prevent the arm from being wearied. The hand of the operator being well smeared with hog's lard, or unsalted butter, he must gradually dilate the external parts by introducing the fingers one after another, moving them in a rotary manner; then begin to dilate the os internum, proceeding gently and gradually, resting at intervals both for his own and the wo-

man's case: when the hand has passed into the uterus, he must break the membranes, but permit not the waters to run off before he has found the feet, and the child is properly turned; the feet secured, proceed as in delivering by the feet. When the child is delivered, if the placenta adheres, but the flooding is not so violent as to render the bringing it away immediately necessary, opiates are the most likely means of promoting the separation and exclusion of it, by relaxing the parts concerned, and removing the stricture which always accompanies the pain: give the tinct. opii gutt. xxx. vel opii gr. ij.

Though many later authors have written well on *abortion*, and some moderns have added many improvements, yet Hippocrates deserves to be read on this subject.

See Dr. Leake's Medical Instructions, edit. 6. and also his Practical Observations. Denman's Aphorisms on Uterine Hæmorrhages. Smith's Letters to Married Women. On the Management of Children, &c. by William Moss, Surgeon. On Uterine Hæmorrhages, by M. Leroux, Surgeon. London Med. Journal, i. 59.

**ABORTIVE MEDICINES.** Medicines designed to procure abortion; with which were we acquainted, we should be cautious of describing. This effect is, however, difficult to be produced; and the most decisive plans have been only effectual by the destruction of the woman. Such medicines have been styled *Ec-bolica* and *Amblotica*.

**A'BRETTE.** See ABELMOSECHUS.

**ABRO'MA**, (from *a* neg. and *βρωμα*, food, i. e. not fit to be eaten.) A tree of New South Wales, which yields a gum.

**ABRO'TANUM**, SOUTHERNWOOD. *A. Mas Caspar Bauhine Artemisia Abrotanum L. Sp. Pl. 1185.—Abr. Fœmina C. Bauh. Santolina Chamæ Cytharissus L. 1179, fœl.*

The leaves of these plants are slightly tonic and diuretic. One species, the "Rupestris," is said by Haller to be warm and stimulant, and employed by the Alpine shepherdesses as an emmenagogue. The female southernwood is supposed to be also an anthelmintic and an antispasmodic. Both are, however, confined to external use, but are not very commonly employed. They are chiefly used as antiseptics, and the female is, as usual, the weaker species. Their appropriate menstruum is alcohol; and, in substance, they may be given from a drachm to any quantity the stomach can bear: in decoction, the proportion may be regulated by the taste, as the power is inconsiderable. Six pounds of the fresh tops afford about a drachm of essential oil, of a bright yellow colour, and of an odour resembling that of the plant.

**ABROTONI'TES**, (from *ἀβροτονον*, southernwood,) a wine impregnated with abrotanum. About one hundred ounces of one, to seven gallons of the other, are put together; and after standing a few days, the wine is fit for use.

**A'BRUM.** See SUCCINUM.

**A'BRUS.** This seems to be the *Glycine Abrus* of Linnaeus, Sp. Pl. 1025, though removed in some of the later systems to a separate genus. It is a plant of both the Indies; and resembling the liquorice in its botanical relations and qualities, has obtained this name, par-

ticularly in Jamaica. This is the plant, whose perforated seeds are employed in forming necklaces.

**ABSCE'DE** and **ABSCEDEN'TIA**, (from *abscedo*, to depart from.) Decayed parts of the body, which, in a morbid state, are separated, *absceded*, from the sound.

**ABSCE'SSIO**, } an ABSCESS; (from *abscedo*, to de-  
**ABSCE'SSUS**, } part;) or from *abs* and *cedo*, to retire.) A cavity containing pus, or a collection of matter in a part. So called, because the parts which were joined are now separated; one part recedes from another, to make way for the collected matter. Termed also *Diaphyema*; *dubletus*, an Arabic term; and *exitura*.

*Αποστήμα* and *αποστασις*, used by Hippocrates, are translated by Celsus, *abscessus*, and sometimes *vomica*. Paulus Ægineta seems to limit the signification of *abscessus* to suppuration, by defining *αποστήμα* to be an *abscess*, or a corruption of the fleshy parts, muscles, veins, and arteries.

The words *αφίσταμαι* and *αφίστημι*, which signify to recede or retire, are used by Hippocrates with great latitude. He means by them any critical removal of offending humours, however discharged; also the change of one disease into another, as a quincy into a peripneumony, &c. See *Apostasis*. But the present practice seems universally to consider an *abscess* as that tumour which follows an inflammation, for almost every abscess is the consequence of inflammation.

The proper seat of *abscesses* is the cellular membrane.

The source of the purulent matter in abscesses is not yet determined. It has been supposed, with some appearance of reason, to be derived from a solution of the solid parts in the exuding serum; and experiments, made by digesting animal substances in serum, have been adduced as supporting this opinion. On the other hand, it has been contended, particularly by De Haën, that purulent matter may be formed without suppuration, without a destruction of the solid parts, or previous inflammation; and it is certain that membranes will, at times, assume a purulent appearance, where little or no previous inflammation has taken place: in such cases, the appearance of pus has been attributed to a change in the state of the extreme vessels, by which they have become secretory organs separating a peculiar fluid. It is also certain, that purulent matter may be distinguished, chemically, from other fluids of the body; and microscopical observations show it to be composed of spheroidal particles, swimming in a fluid. It is, however, evident, that pus is in very few instances, if ever, produced without destruction of the solid parts, which are lost in the fluid discharged; and that new granulations of flesh are formed under its protection. If it destroys the animal substance, it contributes to its reproduction: it regenerates instead of corroding. In this place, however, we speak of mild purulent matter; in the language of surgery, *laudable pus*; the formation of which we shall afterwards attempt to explain. See INFLAMMATION, MALIGNANT ULCER, CANCER, and HECTIC.

The inflammatory heat continuing to increase, in opposition to the usual means, a suppuration will certainly follow. If the patient feels frequent shiverings, a formation of pus is probably commenced. This shivering is pro-

duced by the absorption of some of the pus, or its thinner parts; but when the matter is enclosed in a cyst, or surrounded by an inflamed surface, this absorption rarely or never happens. Whatever be the source of the pus, as it must be derived from the vessels, their tension is removed, the many blood-vessels which before were compressed are freed, the blood circulates freely, the heat abates, and the part is less red, but gradually becomes more soft.

In the progress of an *abscess* on the external parts, the tumour increases, as well as its heat, pain, and redness; a pulsation is perceivable in the tumour, and an evening hectic comes on. The pain and tension then cease, the hardness of the part at length yields to the touch, and the skin bursting, gives a vent to the contained matter.

An *abscess* should be carefully distinguished from a *hernia*, an *aneurism*, and from a *varicous tumour*.

A *hernia*, as will appear hereafter from its seat, its effects, and the absence of pulsation, cannot easily be mistaken for an *abscess*: and a *varicous vein*, as it is neither attended with heat, with pulsation, nor fever, can scarcely ever lead the practitioner into error. An *aneurism* may be supposed to be an *abscess*; or, on the other hand, an *abscess* may be mistaken for an *aneurism*, as each may be attended with inflammation or pulsation. The practitioner, however, who finds a painful tumour beating strongly, if in the course of a large artery, will carefully attend to the previous symptoms. Has much fever preceded? has no violent strain occasioned it? can the finger be passed between the tumour and the artery? It is then an *abscess*. Has the tumour increased slowly, without fever, come on from strong exertion; and does the pulsation, on pressing between it and the artery, appear more evident? It is then *aneurism*: but to this subject we shall return. See ANEURISM.

If, during the treatment of an *abscess*, the patient is sleepless and feverish; if he breathes with difficulty and loathes his food; if the pus when discharged, is ill-coloured, fetid, and sanious; if blood or spongy flesh appears in the cavity of the ulcer; if faintings come on during or after the times of dressing; the prognostic is unfavourable: on the contrary, if these symptoms are absent, or but in a moderate degree, a favourable issue may be expected. By improper treatment an *abscess* is easily converted into a mortification. Deep-seated *abscesses* are sometimes difficultly discovered by the touch; but as no considerable suppuration can happen in the body without being soon after accompanied with a hectic fever, the slightest appearance of this fever at once determines the case.

*Abscesses* from their seat and their consequences are often highly dangerous; and it is of the greatest importance to prevent or discuss them. The *abscess*, for instance, in the *psoas muscle*, is generally fatal. We can, however, seldom succeed in the attempt to discuss them. The *psoas abscess* has, indeed, in the opinion of many practitioners, been prevented by active bleeding; yet, in the early stages, it is with great difficulty discriminated; and to use so violent a remedy for every slight strain would be highly improper. Active emetics have also contributed to dissipate the congested fluids of inflamed parts, and these have at times removed the inflammation of the testicle; but neither remedy can

be employed with the necessary violence in internal inflammations. If we bleed too copiously in pneumonia, we check the expectoration, and the patient dies: if we give emetics in hepatitis, we aggravate inflammation, or burst an *abscess*, if any has formed.

When suppuration is to be promoted, endeavour,  
1st. To convert into pus the congested fluids.

2dly. To assist the discharge of the matter when it is duly digested.

3dly. To heal up the opening, or *ulcer*; for thus the *abscess* is denominated when the matter is discharged.

In order to the accomplishment of the first intention, in strong habits, avoid every stimulant, apply warm and moist applications, which will long retain their heat and not grow hard. The bread and milk poultice, occasionally with the roots of the white lily, united with a little oil, or the meal of lintseed made into a poultice, which contains already an oily matter, are only necessary. Even leeches, which lessen inflammation, will occasionally relieve the vessels, and increase the salutary effusion. If the *abscess* is deep, or the suppuration does not rapidly increase, a little of the digestive ointment may be added to the poultice, a stimulating fomentation may be employed, or a gum plaster laid on the part.

While externals are applied, the state of the constitution is not to be neglected; too much heat endangers a mortification, and with too little every attempt will be abortive. If the heat runs high, reduce it nearly to a state of health by bleeding and a cooling regimen. If costiveness incommodes, gentle laxatives or a clyster may be used. If a defective heat retards the suppuration, warming medicines, and a cordial diet, are required.

For a due fulfilling the second intention, the whole of the tumour, or nearly so, must be converted into pus, before a discharge can be admitted; otherwise all that remains unsuppurated will digest slowly and with difficulty. To this, however, there are some exceptions:—the *abscesses* which are critical in malignant fevers must be opened soon: nature cannot finish the operation; she must be relieved, and the discharge afterwards regulated or corrected. Again, if a due discharge is not obtained as soon as the pus is perfected, it putrifies, and forms an unfavourable opening; or it will be absorbed, and cause a fatal hectic fever. The time of opening is generally to be known by the prominence observed being very thin, the matter fluctuating on the lightest pressure, and an abatement of the pain, heat, and pulsation in the part.

*Abscesses* are opened either with a knife, lancet, or the caustic; but in general the first is to be preferred, for it is less painful than the caustic. The opening may be as far as the skin is discoloured; or a circular piece may be taken out if the discoloration spreads. The opening must be, if possible, in a depending part; or as near to it as nature points. When the bad quality of an *abscess* is likely to retard its future incarnation, an opening made by a caustic best prevents the lips of the wound from growing callous. Venereal buboes, and some indolent or scrofulous tumours, if not in the face or neck, are soonest healed after opening with a caustic; and such of these as neither will give way to suppurating nor discutient medicines are effectually de-

stroyed by caustics, and the eschar soon is cicatrised. See the article *ESCHAROTICA*.

Many advise not to open critical *abscesses* before they are digested. Sharpe says, that "very little of the morbid matter is deposited in them before they are fully ripe, therefore till then they should not be opened." It is certain that, by a premature discharge, the ulcer becomes foul, and heals with difficulty.

When the knife is used, if a nerve, vein, or artery, is in danger, let a director guide the incision, which is best begun on the lower side, for then the matter is discharged most freely, and the operator least incommoded by it. If possible, its course should be according to that of the fibres of the subjacent parts: thus, if the skin is very near a nerve, the use of the part will not be injured by cutting it across.

In some cases, particularly in abscesses of the breast, the abdomen, and in very large abscesses of other parts, where the discharge of the matter *at once* would be injurious from the debility it would occasion, or where the admission of air would be dangerous, a seton is passed, from above, below; (see *SETON*). The matter is then discharged slowly, the access of air prevented, and the irritation occasioned by the motion of the cotton contributes to the diminution of the sac, in consequence of the inflammation excited, which produces adhesion. The length of the upper part of the cotton should be considerable, that it may be drawn down, and the purulent part be occasionally cut off. When the matter of a psoas abscess passing along the fibres of the muscles appears at the surface near the groin, or, penetrating through them, at the back, the matter has been evacuated slowly by using a small trocar, which admits but of a little, if any, air. When the wound closes, the perforation is repeated. We have not, however, found this plan very efficacious.

*As to the third intention*, it may be observed, in general, that, when the opening and discharge are made, the case is considered as a common wound, and the treatment is as directed in the article *VULNUS*. The first dressing may be dry lint, covered with pledgets of soft tow. Afterwards, if the part is tender, and the matter good, when the applications are removed, be content without wiping it very clean, as it is thus irritated. Pledgets that are spread with ointments need not be warmed, except the patient complains of their coldness, and then hold them to the fire, but not so long as that their surfaces melt. Observe a proper posture, which will favour the discharge. Repeat the dressings once or twice a day, as the quantity or the quality of the discharge requires; the seldomer they need a repetition, the sooner will the cure be perfected; and as the air offends not, except by long exposure to it, all hurry is unnecessary. Bell on Ulcers, edit. iii. p. 54. 93. Kirkland's Medical Surgery, vol. ii. 49. 62.

1. *ABSCESSUS ABDOMINIS*. *An abscess of the Belly*. See *INFLAMMATIO MUSC. ABDOM.* N° 10.

2. *ABSCESSUS ANI*. *An abscess of the Anus*. A large quantity of fat fills up the cavity on each side of the anus, and is the seat of this disorder. The causes are various; as *contusions, wounds, inflammations, difficult labour, hard riding, a dysentery, the venereal disease, &c.* Abscesses sometimes are suddenly formed in this part; at others they advance very slowly. *In the first*

*case* the appearances are in the beginning no other than those of a common boil; but the symptoms soon increase, quickly proceeding to a more formidable state. *In the latter*, though the suppuration makes but little progress, the pain and tumour sufficiently determine the nature of the complaint. The pus, whether it makes its way through the skin or through the intestines, is frequently so tedious in its passage, that the adjacent fat is more or less corroded, and sinuses are formed of different shapes and sizes. Sometimes the maturation is extended on every side, rendering the cure both difficult and uncertain. When *abscesses* in this part are left to themselves, they rarely fail to degenerate into fistulas, and occasion troublesome callosities.

As soon as the tumour is formed, endeavour with all possible speed to bring on suppuration; and, when this is in some degree advanced, procure a speedy discharge. To this end, let the patient stand on the ground with his feet asunder, and lean over a table upon his belly; then the operator, introducing a finger into the anus, will perceive the matter in a fluctuating state; in which case, without waiting for the external signs of suppuration, he will make an opening into it with a knife: by pressing the finger in the anus on the *abscess*, and another on the external part, a judgment may be formed where to make the puncture; for, by the finger in the rectum, the pus may be pressed externally, so as to be perceived by the finger there. When the opening is made, endeavour to enlarge the wound as you withdraw the knife; and, for the better application of proper dressings to the bottom, another incision may be made transversely. If the rectum is laid bare, an incision must be made in it also, as far as the accident extends, in order to its reunion with the adjacent parts, for the regeneration of flesh is obtained with great difficulty on the surface of this intestine. When the matter surrounds the anus, the cure is hardly to be performed without cutting off all that is bare. See an extraordinary instance of this kind in the *Med. Mus.* vol. iii. p. 251. 257.

A proper opening being made, the dressings, &c. are as in *abscesses* in general. Though Aetius observes, that when this disorder extends round the anus, while the wound is filling up, a constriction of the circumjacent parts, and an obstruction of the passage of the anus occur; to prevent it he advises introducing a canula there, and continuing it till the cure is finished. But how far a good habit of body, with other favourable circumstances, may encourage our hope of success this way, the practitioner can only judge by the circumstances, and his own experience. When the cause is venereal, these tumours suppurate slowly; and without a gentle mercurial ptyalism a cure is hardly to be effected. See *FISTULA*. See Kirkland's *Med. Surgery*, vol. ii. 201.

3. *ABSCESSUS ARTHRITICUS*. See *ABSCESSUS INTESTINORUM*, N° 17.

4. *ABSCESSUS AURIS*. *An abscess in the Ear*. The symptoms attending an *abscess* in this part have nothing peculiar, except that the pain is very exquisite.—See *OTAGLIA*.

5. *ABSCESSUS AXILLÆ*. *An abscess in the Arm-pit*. Abscesses are often formed by injuries in the arm, hand, or fingers; and sometimes by a fever. When the fever is of a malignant kind, these tumours sup-

purate but slowly; and when ripe, an opening should be made with the caustic; or, if great debility prevails, it must be opened more early with the knife. This disorder when it terminates the plague is usually called a bubo, *g. v.* See also *ABSCCESSUS IN GUINIS*, No. 16.

6. *ABSCCESSUS CA'LEIS.* *An abscess of the Heel.* The common causes of an *abscess* may produce it, but generally it is from scrofula. If there is a caries, the best method is to pass an actual cautery through a canula. Wiseman says it saves much time, and that thus the caries seldom separates in the form of a scale, but moulders away insensibly with the matter.

7. *ABSCCESSUS CA'PITIS.* *An abscess on the Head.* Wounds on the head generally are the most speedily healed; when an *abscess* is brought to the state of a wound, the same advantages attend it, and the common methods suffice for the cure. When *abscesses* are seated on the sutures, they may be troublesome by inflaming the dura mater which passes through them, and is continued to the pericranium. Every where on the scalp, a caustic is the best method of opening *abscesses*, especially if the long confinement of the matter hath rendered the skull carious, for it makes some way for the respiratory, which is always used, except on the sutures: exfoliation here is very slow, therefore rasping is used, and then incarnation can immediately proceed. *Abscesses* over the forehead are best opened by incision; but care should be taken that the direction of the muscular fibres may be followed, for a transverse wound may cause the eye-lids to fall over the eye. *Abscesses* on the head are sometimes owing to a diseased bone from a venereal affection, and are then most troublesome, since in these small vessels the action of mercury is for a long time weak and almost imperceptible.

8. *ABSCCESSUS OE'REBRI.* *An abscess in the Brain.* Instances of this kind have occurred; and if the trepan is used early enough, the case ends well; but it seldom happens that the situation of the abscess can be determined with sufficient accuracy to enable us to employ that instrument, except it is in consequence of external violence. *Abscesses*, from internal causes, are generally seated in the external parts of the brain.

9. *ABSCCESSUS CO'LLI.* *An abscess of the Neck.* This part is affected with tumours of every kind, but generally the scrofulous and encysted occupy it. *Abscesses* here are apt to become fistulous; but by a proper compress and bandage this consequence is often prevented. An opening in this part is best made with a lancet; but if the jugular vein is near, some care is required not to wound it.

10. *ABSCCESSUS DIAPHRA'GMATIS.* *An abscess of the Diaphragm.* See *PARAPHRENITIS*.

11. *ABSCCESSUS DIGITO'RUM MA'NUUM, et PE'DUM.* *Abscesses of the Fingers and Toes.* See *PARONYCHIA*.

12. *ABSCCESSUS DO'RSI et LUMBO'RUM.* *An abscess in the Back and Loins.* For a particular account of this complaint, see *PSOAS, seu LUMBORUM ABSCCESSUS, et ARTHROPOUSIS*.

13. *ABSCCESSUS GINGIVA'RUM.* *An abscess of the Gums, also called Parulis, a Gum Boil.* These tumours are very painful, the inflammation is often more diffused than in other parts, and more or less attended with a swelling in the cheek, or perhaps the whole face.

The tooth-ache, the general causes of inflammation, a carious tooth, &c. induce this complaint. Mr. John Hunter observes, that gum-boils seldom arise from any other cause than inflammation in the cavity of a tooth, the effect of which extends all over the face, but more particularly to the gums; that sometimes this complaint originates from a disease in the socket of the tooth; or in the jaw, without any connection with the tooth. Through bad management, or neglect, they are apt to degenerate into fistulous ulcers. During the inflammation, to assuage the pain, let the patient hold any warm fluid constantly in his mouth, spitting it out, and taking fresh quantities, as may be needful to keep up an equal degree of heat for a considerable time. If the suppuration cannot be avoided, let figs be split and held in the mouth upon the boil, and white bread poultices, wrapped in thin linen cloths, applied externally upon the cheek of the affected side; and as speedily as is convenient let the *abscess* be opened, for the contained matter soon corrodes the adjacent parts, and affects the bone. After the discharge, the poultice may be continued a little longer, and the mouth washed three or four times a day with warm wine and honey of roses. If a bad tooth is the cause, it must be extracted before any attempts are made by medicines, or, at least, as soon as the discharge of the *abscess* will permit. If the ulcer degenerates into a fistula, inject warm wine and honey of roses into it; and if it is suspected that the bone is carious, add to this injection a little of the tinct. myrrh. or of the vin. aloes. If these methods fail, proceed as for the exfoliation of a carious bone. On this subject, see Mr. John Hunter's Natural History of the Human Teeth, part ii. Bell's Surgery, iv. 203.

14. *ABSCCESSUS GLA'NDULÆ LACHRYMA' LIS.* *Abscess in the Lachrymal Glands.* The supposed causes of these *abscesses* seem not to have any such effect. To prevent their usual termination, an opening must be made into them, for the performance of which Mr. Sharpe hath given very ample instructions in his Treatise of the Operations of Surgery. See also Ware on the Fistula Lachrymalis, and Wallis's Nosologia Methodica Oculorum.

15. *ABSCCESSUS HE'PATIS.* *An abscess of the Liver.* A suppuration is prognosticated if an inflammation continues in the liver several days; if the pain remits, and is followed by a pulsation in the same place, and if shiverings come on, with a countenance of a yellowish colour; soon after which a tumour and a sense of weight are perceived in the region of the liver: a hectic fever follows, with thirst, and an extreme feebleness. Aretæus observes, that a pain generally extends to the throat, and to the extremity of the shoulder, and a dry, but not very frequent, cough afflicts the patient. He further remarks, that this disorder is sometimes mistaken for a tumour of the peritonæum; but that the latter is more irregular, and is not circumscribed by the limits of the hypochondrium.

The consequences of an *abscess* in this viscus are:

1st, The liver is corroded and consumed. In this case, after a tedious icterical wasting, a slow fever, great anxiety, a sanious and fœtid diarrhœa, &c. the patient dies.

2dly, The *abscess* breaks inwardly, and discharges a sanious pus into the belly: thus the rest of the viscera

are affected, a consumption of the whole body hastily advances, and an ascites, &c. usher in death.

3dly, The pus sometimes passes by the biliary ducts into the intestines, and, regurgitating into the stomach, causes dark, offensive vomitings; or passing downwards, produces a violent diarrhœa. Acid and acescent substances may palliate for a time, but the end is always fatal.

4thly, The tumour may adhere to the peritonæum, and form an external *abscess*, evident both to the sight, and touch. *Here alone is any hope to perfect a cure*: a caustic may be applied and left to suppurate; or, if the pulsation be evident, an opening may be made with the knife. If the pus is well conditioned, and the symptoms soon subside, the patient will recover; but, otherwise, this case is also fatal in its end.

5thly, Aretæus informs us, that if the tumour does not suppurate, the excrements have an offensive and putrid odour; the food passes crude and undigested, because of the weakness of the stomach and of the intestines; for the liver, so disordered, sends forth bile too defective to assist the digestion; whence some are afflicted with a sharp corroding heat, are daily worse, and death is soon their delivery. Some recover from both the dysentery and the *abscess*, but a dropsy terminates the scene. If, however, these symptoms remit, and the pus in the stools becomes white and of a good consistence, and the patient can again digest his food, we may still hope. As the best crisis, he notes that by urine, for thus the least offence is given. See Bell's Surgery, v. 387. Kirkland's Med. Surgery, ii. 185. London Med. Journal, vii. 22.

16. *ABCESSUS IN GUINIS.* *An abscess in the Groin*, is sometimes occasioned by injuries done to the parts below, as in the knees, legs, or toes; a pestilential fever may be the cause, in which an *abscess* in the groin is often critical, but the venereal disease is the most frequent. See Bubo. If opened with a knife, be careful not to wound the inguinal artery. In venereal cases a caustic is preferable, as it dissolves part of the induration which too often remains after the greatest part is suppurated, and assists in digesting the remainder. If *abscesses* in the groin, or in the arm-pit, are from the crisis of a fever, the caustic should be employed, and the discharge kept up, till all danger from the fever is over. In glandular parts all that is hardened should be perfectly dissolved; for instances have occurred of cancers proceeding from the remaining indurations.

17. *ABCESSUS INTESTINO'RUM.* *An abscess in the Intestines.* When an *abscess* in the intestines is discharged, the case is sometimes mistaken for a dysentery; indeed, if the ulceration continues long, its treatment will be the same as in the dysentery, though at first the methods are far from similar. Before an *abscess* is formed in these parts, there is always a throbbing pain felt near the part affected. At the beginning of the suppuration there are unequal shiverings, which increase and remit; and a fever, with exacerbation of the symptoms in the evening. When this accident follows an inflammation in the bowels, it begins in about four days after the attack of the inflammation, at which time a shivering comes on, which extends through the whole body; and an obtuse pain, with a sense of weight, is perceived in the part affected. After the pus is formed, the symptoms abate, and the pain nearly

ceases, till the time of breaking approaches, and then the pain is renewed; but it is of a different kind, not pulsatory and shooting, but tensive, with a sense of weight. Sometimes the belly is violently constipated; and, after the discharge, a quantity of aqueous pus is thrown out by stool. See Aetius Tetrabib. iii. serm. i. cap. 42. In about fourteen days the pus makes its way into the cavity of the belly, and produces inconveniences similar to those arising from a discharge of the like kind from the liver: or, passing into the intestines, it runs off by stool. In this case, entire membranes are discharged, and a consumption often follows.

If, on the first attack, the means recommended against an inflammation of the intestines fail, little more is to be done than to supply the patient with emollient and gently detergent broths, to support his strength by bark, and sheath the suppurated parts by a mixture of wax and soap. Opiates should be given, to relieve pain, and, by lessening the action of the intestines, to allow the pus to thicken, under which new granulations may form. If, by the continuance of the excretions, the dysenteric state is produced, the same means are to be employed as in a dysentery.

Musgrave, in treating of the irregular gout, observes, that sometimes a gouty dysentery degenerates into an *abscess* in the bowels; hence properly called *ARTHRITICUS*. Celsus indeed observes, that large *abscesses* in these parts are sometimes the consequence of fevers and pains, especially of pains in the belly. If the purulent discharges are excessive, moderate them with small doses of the tinct. opii; in case of faintness, a glass or two of wine may now and then be allowed; avoid all acids, acrids, and high cordials, and let the diet chiefly consist of jellies, agglutinating broths, &c.: at last, when all appearances of purulency have vanished, the myrrh, or the bals. Peruv. in a decoction of bark, may be used, both to restore and to prevent a relapse. Warner on the Gout.

18. *ABCESSUS PERITONÆI.* There are some instances of apparent inflammation of the intestines, where the peritonæum is only affected. The disease we shall particularly notice under this title, when we shall add the methods of distinguishing it, and the remedies adapted for it: at present we shall only remark, that *abscess* is its common termination; and, as the whole membrane is affected, even when the existence of the disease is certain, the cure is hopeless. The patient often lives for a long time, but sinks, at last, in an incurable hectic. See PERITONITIS. An *abscess* rarely occurs in the muscular parts of the abdomen, without an affection of the peritonæum. Should it happen, it must be rapidly brought forward, though there is little hazard of its penetrating inwards.

19. *ABCESSUS ISCHIA'TICUS.* *An abscess in the Hip*, a species of *Arthrophuosis*. When an *abscess* forms itself in the socket, or the head of the thigh-bone, there are usually a great swelling and lameness in the hip, and in time matter collects in this cavity. Instances have also occurred in which it hath passed through the bottom of the acetabulum into the belly; and in these cases, when the patient went to stool, the matter, by straining, was forced back, and through the external wound. Mr. Pott observes, that this disease originates in the hip-joint; yet, in this case, the leg of the affected side is shorter than the other, the pain begins where the disease

originates, i. e. about the great trochanter. "It is (he says) a distemper of the joints and ligaments that surround it." He further adds, that, "if we see scrofulous affections of any kind, in the beginning, if there is any remedy in art, I believe it to be issues; therefore, in scrofulous hips, apply a large caustic on the part, large enough to admit of five or six peas, and keep up the discharge as long as it appears to be necessary." Alas! though this method, if early used, is much to be depended on, like many other valuable means, it is usually applied too late. It is distinguished from a relaxation of the hip-joint by a painful tumour, hectic fever, &c. Issues may be useful in both; but the Bath waters, recommended in cases of relaxation, would be fatal in cases of abscess.

20. **ABCESSUS LUMBO'RUM.** See Psoas, seu Lumborum Abcessus.

21. **ABCESSUS MANUUM.** *Abscesses on the Hands.* For the most part they are strumous; when not, the common methods suffice for their removal.

22. **ABCESSUS PROPE MAXILLAS.** *Abscesses about the Jaws.* Besides the common causes, a carious tooth, the tooth-ache, an injury done to the socket of the jaw in extracting a tooth, &c. may produce an *abscess* in these parts. *Abscesses* under the chin are frequently found in children, but they easily give way to the common methods. The conglobate glands under the jaws are very subject to suppuration, and are often mistaken for strumous swellings, but they differ greatly from them. The strumous kind are contained in a cyst, which requires to be destroyed by escharotics after the matter is discharged; but these are managed and cured with ease by the ordinary methods of digestion.

23. **ABCESSUS MEDIASTINI.** *An abscess of the Mediastinum.* In such situations there is but little to be done for the relief of the patient: however, it is observed by several practitioners, that in the venereal disease this disorder is peculiar and frequent. The use of the trepan has been recommended to give an opening to the matter, through an aperture in the sternum. The attempt would, however, be rash and injudicious. The presence of matter, in the mediastinum, is always uncertain, and its situation more so. The admission of air also into this cavity must be highly dangerous: yet it has been attempted with apparent success by Mr. Blair (London Medical Review, vol. iv). A paper on this case occurs in the xvth volume of the same work. The cavity of the chest has certainly been opened with advantage to discharge water, pus, and wind. See Kirkland's Med. Surgery, ii. 183.

24. **ABCESSUS MESENTERII.** *An abscess of the Mesentery.* Suppurations in this part are not suspected, because neither heat nor pain is to be perceived in it; but these symptoms, though common, yet are not essential to inflammation and suppuration, as they depend on the sensibility of the parts. It may be observed, that pus is no where more readily formed than in parts where the texture is loose; and *abscesses* in the mesentery are far from being rare, and are generally to be discovered by a continual hectic fever, an oppressive uneasiness in the belly, a discharge of a sanious matter by stool, and sometimes pain and heat in the intestines. The sanious matter is also not unfrequently absorbed by the lacteals, mixed with the blood, and conveyed to the glands of the trachea, the kidneys, &c.

Hence large imposthumes of the mesentery are often accompanied with discharges of purulent urine, or a spitting of purulent matter, though at the same time no injury hath happened either to the lungs or to the kidneys. If the *abscess* is seated in a place less fit for the excretion of its contents, very troublesome pains, resembling a colic, are produced: if the matter is discharged into a cavity of the belly, it soon produces a gangrene. Horstius, Bartholine, and Tulpius, give instances of the pus being emptied into the cavity of the intestines, and discharged by stool; but, notwithstanding all these circumstances, for the most part the diagnostics are very obscure; nay, these *abscesses* have been unsuspected, and dissection after death hath alone discovered them. If these tumours are suspected, they must be distinguished both from an inflammation and a scirrhus. In general, the prognostic is doubtful; for if the *abscess* breaks, and discharges a putrid matter into the belly, sudden death follows: if after the rupture the ulcer is not speedily cured, it induces a gangrene, a dropsy, or a consumption. If this complaint is manifest, and the tumour can be perceived, emollients may be applied externally, and internally may be administered aperient and gentle purgative medicines, and remedies used in obstructions of the liver and spleen, &c. These suppurations are generally in the glands of the mesentery, and are then symptoms of scrofula. These glands are often found after death in a scirrhus state, and thus are frequently the companions of a cancer here, or in some other glandular part. Riverius speaks largely and well on this subject. See his Prax. Med. lib. xiii.

25. **ABCESSUS NARIIUM.** *An abscess in the Nostril.* *Ozana.* This, from the pain it occasions, is exceedingly troublesome. If in the inflammatory state it can be removed by bleeding, purging, blistering the back, &c. much trouble to the patient will be saved; if, in spite of all, suppuration advances, emollient injections may be thrown up the affected nostril, and a warm cataplasm laid upon the nose. Wiseman observes, that the matter, when digested, is very tough. See Bell's Surgery, iv. 76. Pearson's Principles of Surgery, i. 255. White's Surgery, 265.

26. **ABCESSUS NYMPHÆ.** *An abscess in the Nymphæ.* See ALÆ.

27. **ABCESSUS O'CULI.** *An abscess in the Eye.* From the small-pox most frequently, though from other causes this accident sometimes happens. When the seat is in the transparent part of the cornea, it is discovered by the peculiar whiteness of its appearance. When it is in the opaque part of the cornea, the eye is swelled, but more particularly so where the *abscess* is seated. If its seat is deeper, the first evidence of its existence is generally the extravasation of its contents in the aqueous humour. Those on the transparent cornea are generally cured by cautiously opening them with the point of a lancet, carefully avoiding the pellicles of this coat which lay beneath. In the other two kinds there is great danger of losing the sight, for they discharge themselves into the anterior chamber of the eye; though sometimes a cure is effected without any remaining inconvenience. When the matter of these diffuses itself so as to spread over all the pupil of the eye, then is formed the hypopyon; if only a part of the pupil is covered, the matter forming itself into a speck

like those at the bottom of our nails, is called an onyx. Heister, in his Surgery, gives a different account of the hypopyon and the onyx. In the cure of the chemosis, first use remedies to resolve the inflammation; if these fail, proceed as follows. While the contents of the *abscess* are not yet dispersed, but extend into the hole of the pupil, place the patient fronting a good light, with his head laid on the back of an easy chair, then make an incision into the transparent part of the cornea, under the hole of the pupil, taking care that the point of the lancet does not touch the iris, which lies behind the pus; make the aperture long enough to give a free vent, then gently inject a little warm water therein. Afterwards apply a compress, wetted in a collyrium of rose-water, well mixed with a little of the white of an egg: keep the compress constantly moist with this fluid by sprinkling it from time to time, and drop some of it three or four times in the day in the orifice on the cornea. Some days after the first discharge, a fresh collection of pus sometimes presents itself, which is discharged by introducing a fine stilet into the incision. See on these subjects Wallis's *Nosologia Methodica Oculorum*.

27. *ABSCCESSUS OSS'IIUM.* *An abscess of the Bones.* Observations in practice prove, that not only in the cellular parts near the joints, but also in the middle cavities of the large bones, inflammations have degenerated into *abscesses*. The observation of Ruysch, in which he says, "that he found, in the middle cavities of the large bones, round bony pipes, separate from the rest of the bones in which he saw them," may be referred to this article. See *ABSCCESSUS PERIO'STEI*. 35.

28. *ABSCCESSUS PALPEBRÆ.* *An abscess in the Eye-lid,* when externally situated, requires no peculiar management different from *abscesses* in general, except that in opening it, when situated near the cilia, great care is required not to enter the lancet any deeper than is barely necessary to evacuate the *abscess*; if the edge of the eye-lid is cut, an incurable wateriness is endangered. The direction of the incision is safest in the course of the orbicular muscle. An *abscess* situated on the inside of the eye-lids may be opened with a lancet, and then washed with brine, or other proper collyria.

29. *ABSCCESSUS PANCREA'TIS.* *An abscess of the Pancreas.* This complaint is the most common in scorbutic habits. Riolan says, that its presence is properly guessed at by a sense of weight in the region of the stomach, no hardness nor tumour being manifest in the hypochondria, particularly if there are other marks of latent obstructions in the abdominal viscera; a difficulty of breathing from the compression of the diaphragm also occurs; and sometimes by pressing near the side of the stomach a tumour is perceptible, and then the pressure causes pain. *Though the diagnostics are generally very obscure or uncertain, yet it may be observed that a hectic fever, long watchings, short sleeps followed by a sense of weariness, fainting, and cold sweats, are certain attendants of this disease:* Yet the same symptoms attend *abscesses*, and even infractions of the other viscera; and no peculiar plan of treatment is applicable to the *abscess* of the pancreas. See Riverius's *Prax. Med. lib. xiii. cap. 4.*

30. *ABSCCESSUS PARO'TIDIS.* *An abscess of the Parotid Glands,* also called *Parotis*. The parotid glands suppurate with difficulty; the less so when the general

habit is disordered, when a venereal, scorbutic, pestilential, or other affection attends. They are apt to become fistulous; though, when they arise in children, unattended by any other disease, there is no danger of ill consequences; and in such circumstances the best remedies are purgatives, mixed with small doses of calomel, frequently repeated. In more advanced life, Trillian lays it down as a rule, that the cure must begin with bleeding: and Celsus, with great judgment, proposes, that, "when the parotis is unattended with any other disorder, the cure may begin with repellents and discutients; but, on the contrary, if any other complaint hath preceded or attends, suppuration must be immediately promoted." The management under suppuration is the same as in other similar cases, viz. the *Bubo*, q. v. and Kirkland's *Med. Surgery*, ii. 142. In some instances, it begins without any fever, like a swelling of a conglobate gland. It enlarges considerably, suppurates in one minute point; and the whole soon becomes a ragged foul ulcer. A hectic, with considerable emaciation, terminates the complaint. We are seldom aware of its nature soon enough to employ medicine: and from its event this has been styled a malignant parotid.

31. *ABSCCESSUS PEC'TORIS et MA'MMÆ.* *An abscess of the Breast.* For the former, see *VOMICA*. The latter is an external disorder, which happens, for the most part, to women. Bruises sometimes are the cause; but, generally, a too active separation of the milk, or taking cold while the woman continues to suckle. Inflammation of the lungs and pleura often produce *abscesses* in the breast, externally, and upon the ribs, which, in bad constitutions, prove fistulous, and render the bones underneath carious. A frequent cause is from not letting the child suck until two or three days after its birth. An early application of the child to the breast, or otherwise emptying the breasts before they are turgid with the milk, would in general prevent this complaint. Another cause is the use of astringents, to repel the milk. When an *abscess* arises from the milk, it is called *sparganosis*. If these *abscesses* burst at the top, sinous ulcers are sometimes the consequence; and this happens, too, from laxity in the habit, and a debility in the constitution. When inflammatory tumours happen in the breasts of pregnant women, or of those who are nurses, we ought to be very cautious in the use of repellents; in sanguine habits, bleeding and opening medicines are necessary, with a cooling regimen. If such tumours do not very easily and speedily give way, suppuration should be promoted, for this is the best way of preventing its increase, but the supposed bad consequences have no real foundation, for a cancer is never the consequence of a milk-sore. The common white bread poultice, for neatness and efficacy, equals, if not excels, all other applications, as a suppurant in these cases; it should be applied, and renewed as frequently as is necessary for keeping up an equal warmth, which will be every two or three hours, and continued till the *abscess* breaks of itself; and then we have only to enlarge the opening a little, if it be too small, or alter its direction if not sufficiently low. A small opening is generally preferable to a large one, as it heals both sooner and more kindly; some advise to make an opening during the state of inflammation, because of the pain which attends these tumours; but

by these premature discharges fresh collections will be formed, and thus may the whole breast be wasted. An *abscess* here should be opened by incision, never by a caustic: only if the lancet passes near the nipple, if possible, it should be directed semicircularly, both to avoid cutting it, or the areola, for thus the beauty of the part is best preserved, and future suckling not prevented. It sometimes happens that, in order to heal a present *abscess*, or to prevent the formation of new ones, it is absolutely necessary to wean the child, and gradually divert the milk from the breasts. See Bell's Surgery, v. 396. Kirkland's Med. Surgery, ii. 160—175. Pearson's Principles of Surgery, i. 73, &c. White's Surgery, 441.

32. *ABSCUSSUS PE'DUM.* *Abscesses in the Feet.* Of all the sorts that affect these parts, the strumous, which are most common, are the worst, for in these instances the bones are usually affected; but *abscesses* of every kind are bad, as they are apt to form sinuous ulcers, and produce caries in the bones. The applications and general management are here as in other cases.

33. *ABSCUSSUS PERICA'RDI.* *An abscess of the Pericardium.* Little has been said by authors concerning this subject, any further than dissections have proved that such a disease exists, and that it has sometimes come on independent of any symptoms indicative of pneumonic affections, with which the state preceding suppuration is often joined. If these have preceded, the usual methods of checking inflammation must be attempted.

34. *ABSCUSSUS PERINÆ'I.* *An abscess in the Perinæum.* An *abscess*, if suspected to be forming in this part, should be prevented, because of its troublesome effects; it retards, or totally prevents, the discharge of urine. In other circumstances it may penetrate into the bladder, or rectum, and produce a troublesome or incurable fistulous opening. It may happen from any cause, but the most common origin is a venereal affection; and we have seen it from a misplaced gouty inflammation. It requires no peculiar treatment, except particular care to keep the abscess clean; and as the part is seldom susceptible of very active inflammation, the applications should be warm and antiseptic. The original cause will require minute attention according to its nature. See a singular case in Le Dran's Observations. See Kirkland's Med. Surgery, ii. 253. and Pott's Works.

35. *ABSCUSSUS PERIO'STEI.* *An abscess of the Periosteum.* This case is known by evident inflammation, swelling, and pulsation in the part, and irregular shiverings. As the suppuration approaches and proceeds, all the symptoms are augmented; but the principal sign is the irregular horripilation. Sometimes the diagnostics are obscure, because the quantity of matter collected, though productive of violent symptoms, is too small to raise a sensible tumour, and in such cases the pain does not remit, though the pus is formed; besides, the matter gradually increasing in quantity, unless it corrodes the periosteum, passes between it and the subjacent bone, and thus, by gradually separating them, keeps up a most violent pain. An accident of this kind soon lays the bone bare, and corrupts by destroying the vessels which nourish it. If the pus corrodes the periosteum, and spreads through the softer parts, it produces fistulous ulcers. When this disorder is manifest,

a speedy discharge is to be aimed at, and the bone must be treated in the same manner as the skull when denuded. First make an incision through the teguments only; for when the periosteum is corroded, the matter generally soon makes a way betwixt the muscles, in which case it is a guide to the operator in piercing to the bone, which, when laid bare, the remaining procedure will be as in deep *abscesses*, and when the skull is deprived of its pericranium.

36. *ABSCUSSUS PLE'URÆ.* *An abscess of the Pleura.* When this is suspected, an opening must be made into it as early as possible, lest it burst into the cavity of the breast, and form an empyema. As it seldom happens, however, that the pleura is affected, without some previous inflammation of the lungs, and as the lungs more readily suppurate than the denser membrane, we scarcely, in any instance, find this abscess unmixed. When it does occur, and shows its real seat, by a slight external tumour, it may be opened with a small trocar, or more safely by a caustic, fixing the caustic rather below the part where the tumour is most full. In this way, if the strength be supported, we have more than once preserved the patient's life, though the lungs were affected. When the case is more clear, as where it happens from an accident, and the pleura is alone affected, a blister (rendered perpetual) or a seton, will only be necessary; and these will effectually prevent its opening into the cavity of the breast. See many satisfactory remarks on this subject in Sharpe's Critical Enquiry, and in Le Dran's Observations and Operations.

37. *ABSCUSSUS PUDE'NDÆ.* *An abscess of the Pudenda.* See *ALÆ.*

38. *ABSCUSSUS PULMO'NUM.* *An abscess of the Lungs.* See above *ABSCUSSUS PLEURÆ*, et *VOMICA.*

39. *ABSCUSSUS RENIS.* *An abscess in the Kidney.* When an inflammation in the kidney suppurates, it is known by the following signs; viz. a remission of the pain, which is succeeded by a pulsation, a frequently returning horror, a weight and stupor in the part, with a heat and tension; the urine is purulent and fetid sometimes, and, at others, a whitish pus is discharged with it, in which is nothing offensive. If this suppuration continues some time, the whole kidney being consumed, it forms a kind of bag of no use; and in this case, a *tabes renalis* is frequently present; but if a small quantity of the inflammatory matter remains coagulated in the minute folliculæ of the urine, it forms a basis to which the sabulous matter, which continually is passing by it, will adhere, and gradually form a stone, and which, also, by the same means will be augmented. When the *abscess* is burst, the urine becomes purulent: and though in these cases the discharge ceases, the kidney shrinks into a withered state, and all complaints are ended at some certain period; yet, to hasten this relief, diluting and gently diuretic liquors may be used, gentle laxatives and balsamics also, and probably the bark may much conduce to expediting a cure. An *abscess* of the kidney is, however, more frequently of a chronic nature, without previous observable inflammation, as the part is not acutely sensible, and the seat of pain in deep parts not to be referred with accuracy to one spot. Stone in the kidneys, from a nucleus of pus, is in these cases very uncommon, and indeed rare in every other.

40. *ABSCCESSUS SINUS MAXILLA'RIS.* *An abscess in the Maxillary Sinus, called the Antrum Highmorianum.* Drake mentions this as a species of ozaena. It is known by a pain which is deep seated in the nose, eyes, and cheek, and a tumour on the outer and upper part of the latter; a discharge of offensive matter from the nostril of the affected side, especially on inclining the head to the side that is sound; sometimes the breath is rendered very disagreeable by the caries produced in the teeth by this disorder. Mr. John Hunter observes, in his Natural History of the Human Teeth, part ii. that, "The pain in this disease is at first taken for the tooth-ache; however, in these cases, the nose is more affected than is observed in a tooth-ache. The eye is also affected; and it is very common for people with such a disease to have a severe pain in the forehead, where the frontal sinuses are placed; but still these symptoms are not sufficient to distinguish the disease. Time must disclose the true cause of the pain, for it will commonly continue longer than that which arises from a diseased tooth, and will become more and more severe; after which, a redness will be observed on the fore part of the cheek, somewhat higher than the roots of the teeth, and a hardness in the same place, which will be considerably circumscribed; this hardness may be felt rather highly situated on the inside of the lip." The method of cure by drawing one of the dentes molares from the affected side was first proposed and practised by Drake, and his improvement hath been continued with the happiest success. Draw the last tooth but one; and, if rotten, draw the next on each side of it, then through their sockets make a perforation into the antrum with a large awl; the matter being discharged, the cure may be finished by injecting a mixture of aq. calcis, tinct. myrrh, and mel rosæ, twice a day into the cavity, and retaining it with a tent. See Gooch's Cases and Remarks, in which an extraordinary instance is related, with the subsequent ingenious and successful management. Mr. John Hunter proposes to effect the cure as follows: 1st, if the disease is known before the destruction of the fore part of the bone, make an opening through the partition between the antrum and the nose; or, 2dly, by drawing a tooth, as above: the latter method he prefers. Bell's Surgery, iv. 209. Kirkland's Med. Surgery, ii. 150.

41. *ABSCCESSUS SPIRITUO'SUS.* See ANEURISMA.

42. *ABSCCESSUS SPLE'NIS.* *An abscess of the Spleen.* This viscus is rarely the seat of *abscess*; but when it is, and the suppuration is completed, for the most part it is easily perceived by the pressure of a finger; when this tumour is ready to break, the nausea and anxiety are very great. Sometimes, indeed, an *abscess* is formed on this part, and escapes all observation, on account of its exciting no uneasy symptoms. Lommius says, in his Medical Observations, that "an *abscess* in the spleen is attended with nearly the same signs as the same complaint in the liver:" and Aretæus observes, that a dropical kind of swelling attends the patient, his skin is of a blackish and greenish colour, he is restless, breathes with difficulty, his belly is tumid with vapours, and there is a sort of cough, by which little is discharged." When this kind of *abscess* bursts, there is no pure digested pus, but an ash-coloured, or a brown or livid matter; and if it is deep, a blackish sort of humour,

with some of the juice of the tabid spleen, is evacuated. If the fæces are watery, and become more so, the disorder ends well; but if the ulcer continues long, a loss of appetite comes on with a general bad habit of body, livid coloured and foul ulcers break out, particularly on the legs, and, in short, a stop is put to affliction only by death's approach. Endeavours to prevent suppuration should not be neglected as soon as the complaint is perceived; if those fail, cataplasms of the briony root are preferred, as the most effectual digestive. See Oribas. De Morb. Curat. lib. iii. cap. 43. Paulus Ægineta, lib. iv. cap. 18. Asiatic Researches, vol. vii. for the Indian method of cure.

43. *ABSCCESSUS TEMPORA'LI'S MU'SCULI.* *An abscess of the temporal Muscle.* The violent pain occasioned by an inflammation and suppuration in this part is from the confinement of the matter under the tendinous sheath which covers it. If not evacuated, it passes under the zygomatic process on the outside of the dentes molares, and from a tumour there it may be discharged. Dr. Hunter observes that when the pain hath been violent, and the fever thus excited considerable, he hath with advantage made an incision along the muscles; and he advises, when an inflammation is considerable, that we open the part without delay, for we never can perceive any fluctuation there, as the fascia is so tight. See Kirkland's Medical Surgery, ii. 133.

44. *ABSCCESSUS TE'STIUM.* *Abscess of the Testicles.* See HERNIA HUMORALIS.

45. *ABSCCESSUS TONSILLA'RUM.* *An abscess of the Tonsils.* *Abscesses* in this part endanger suffocation. If bleeding, purging, or blistering behind the ears do not succeed, and a suppuration should take place, incisions may be made with a lancet into the body of the tumour. Thus, by discharging some of the blood and humours before they are formed into pus, the dangerous degree of swelling is prevented. It is never prudent to leave the matter till it is formed into perfect pus; but, at the latest, the puncture should be made as soon as the appearance of digested matter can be perceived. It happens sometimes, that when the patient is on the point of suffocation, a sudden spontaneous discharge gives instant relief; as soon as the tonsils have emptied themselves, they contract, and by the assistance of a gargle, made with the decoct. cort. Peruviani et mel rosæ, a cure is completed in a few days.

46. *ABSCCESSUS U'TERI.* *An abscess in the Womb.* When the inflammation begins to suppurate, bladders of warm water should be applied over the part; and sitting frequently over the steams of warm water should be advised. Oribasius observes, that these *abscesses* sometimes discharge themselves into the cavity of the uterus, at others into the intestinum rectum, or into the bladder. Forestus says, that if the discharge is into the cavity of the womb, and is whitish, the patient may recover; but if the *abscess* continues long, the discharge becomes greenish or dark-coloured, and offensive with lancinating pains, the greatest danger is to be apprehended.

47. *ABSCCESSUS VE'SICÆ URINA'RIÆ.* *An abscess in the Urinary Bladder.* An inflammation in the bladder is sometimes followed by an *abscess*. When this happens, it is known by an exacerbation of the symptoms, and a sense of weight in the parts about the perinæum and pubes. Emollient fluids, mixed with

warm milk, may be injected into the bladder very frequently, to hasten the suppuration, and to solicit the discharge into its cavity. Besides injections, warm emollient clysters, with powdered opium in substance, should be given and often repeated; with gentle laxatives either of castor oil or soap interposed. Warm poultices may be applied to the perinæum or pubes, according to the seat of the pain. When the pus is formed, the bladder may be frequently washed according to the plan recommended by Jesse Foot. If the pus is not soon evacuated, it acquires an acrimony, and corrodes the adjacent parts, produces fistulas, and other inconveniences. If the injections fail, there is no resource but that of an operation; and, though rarely required, two examples of it are recorded in Boneti Sepulch. lib. iii.

An ulcer of the bladder or of the kidneys is, however, an uncommon complaint. We sometimes find an apparently purulent deposition in the urine, which consists of a light mucus only, from a disease to be afterwards noticed, Catarrhus Vesicæ. Previous painful affections of the bladder, with fever, and an offensive smell, chiefly point out the existence of the abscess. Without these, the disease is probably only a catarrh. In a long and extensive practice, we have seen only two cases of inflammation of the bladder from an internal cause, neither of which had the slightest tendency to suppuration.

Authors to be consulted on *abscesses* are Hippocrates, Aretæus, Celsus, Paulus Ægineta, Oribasius, Aetius, Actuarius, Hildanus, &c.; and among those of later date, Boerhaave, Wiseman, Turner, Heister, Sharpe, Dease, and Bell.

ABSCIS'SIO, an ABSCISSION, or cutting away one part from another, (from *ab*, and *scindo*, to cut); called also APOCOPE.

This word is used in many senses, but mostly to express the cutting away an unsound part, and that a soft one; for the cutting away of bones is called amputation; though, when small fragments only are to be separated, the word *abscissio* is sometimes used. This word also expresses the sudden termination of a disease in death, before it arrives at its decline. Celsus, to express a loss of voice, frequently uses the term *abscissa vox*.

ABSCO'NSIO, (from *abscondo*, to hide). A sinus, or cavity of a bone, which receives and conceals the head of another bone.

ABSINTHI'TES, (from *absinthium*, wormwood). A wine impregnated with wormwood. This has been considered as a wholesome drink, preventing indigestion, obviating the effects of drunkenness, and a preventive of venery. Others have accused it of affecting the head. It is, however, little more than a pleasing form of the wormwood. q. v.

ABSINTHI'UM. WORMWOOD.

Αψινθιον, *unpleasant*, (from *a* neg. and *ψινθιον*, *pleasant*). But authors vary much in the account of the etymology of this word. However, the English name is originally an Anglo-Saxon one. "It is one amongst the most famous of the bitter plants, (says Dr. Cullen,) and has been used with much commendation for every purpose of bitters; the leaves of the *absinthium* vulgare are the best."

VOL. I.

Botanists enumerate no less than thirty-two different species.

The sorts in use are as follow:

1. ABSINTHIUM VULGA'RE, Absynthium Caspar Bauhine. ARTEMISIA ABSINTHIUM, Lin. Sp. Pl. 1188. Natural order, compositæ discoideæ. Menstruum, water and rectified spirit. Mat. Med. 386.

COMMON WORMWOOD. Leaves—dose ʒi to ʒi.

2. ABSINTHIUM ROMA'NUM, *absinthium* minus. It is the ARTEMISIA PONTICA, Lin. Sp. Pl. 1187. A. Ponticum tenuifolium incanum, C. B.

ROMAN WORMWOOD. A native of Hungary and Thrace.

3. ABSINTHIUM MA'RITIMUM, Artemisia Maritima, Lin. 1186; A. Seriphium Belgicum, C. B.

SEA WORMWOOD.

This is also called Roman wormwood, but very improperly. It grows in our salt marshes, and on the sea coasts, is a strong bitter, and was formerly much used in medicated ales and wines, as a stomachic and corroborant.

All the species have nearly the same properties. The *absinthium maritim.* is less unpleasant than the *absinthium vulg.*; even its essential oil is more agreeable than the oil distilled from the other. This species is not so antiseptic as the common sort, but it is a better stomachic; and in this it differs but little from the Roman. The *absinthium Romanum* is less disagreeable than either the common or the sea wormwood, and is the most eligible of the three as a stomachic and corroborant; it agrees with the abrotanum femin. and with the flores chamæmel. better than with the *absinthium com.* being less stimulating; the *absinthium maritimum* is often substituted for it.

The common wormwood hath a strong smell, and is intensely bitter to the taste. These qualities are most remarkable in the leaves, which lose part of their ill smell by drying. The flowers are nearly as bitter as the leaves, but less nauseous; the roots are warm and aromatic, without the bitterness of the other parts of the plant.

The whole plant powerfully resists putrefaction, and is a principal ingredient in antiseptic fomentations. It is a warm stomachic; its extract, made with water, is a very agreeable and simple bitter, and is the best mode of giving this medicine. Taken in vinegar, it is said to remove the oppression occasioned by eating mushrooms, and to be an antidote against the poison of hemlock.

The herb gives out all its virtues by maceration, either to water, or to spirit; but the watery infusion without heat is the most grateful. Bergius considers this plant as an antiputrescent, antacid, anthelmintic, resolvent, tonic, and stomachic. It is, however, only a grateful stomachic, slightly tonic, and in an inconsiderable degree diuretic. Its chief use is in dyspepsia, gouty debility of the stomach; and, like all other bitters, it has been of service in calculous complaints. It is an ingredient in the duke of Portland's powder for the gout, and suspected, from thence, to have a narcotic power.

The preparations of wormwood are deservedly rejected from the British and Irish pharmacopœias, and indeed they require no peculiar management. The

D

essential oil is recommended by Hoffman as an antispasmodic and anodyne, and by Boerhaave in tertians; but modern Dispensatories reject the preparation, and modern practice supplies more effectual remedies. The name of the salt of wormwood remains, and some have thought that saline draughts, made with it, sat more easily on the stomach; but the salt itself is no where to be found.

**ABSENTHIUM SANTON. INDIC.** See **SANTONICUM**.

**ABSORBENTS.** **ABSORBENT MEDICINES**, (from *absorbo, to suck up*). This was formerly an important class of medicines, at present it is reduced below its proper level; and it will be useful to appreciate the real value and object of absorbents.

In a general sense these medicines are such as will absorb acrimony; in a more limited one they are styled *Antacids*, *Antalkalines*, and sometimes *Antacrids*. The simplest view that we can take of their operation, is in the application of dry flour to the skin, in cases of erysipelas: flour, in this case, truly absorbs the acrid matter flowing under the cuticle, and occasionally passing through it, thus extending the inflammation. Its action is consequently mechanical; and dry flour absorbing the blood in slight hæmorrhages, and forming an artificial thrombus, a support to a wounded artery, is equally a mechanical effect. We can proceed further: when the mucilage of gum arabic, an unleavened biscuit, or a similar substance, prevents heartburn, each acts by absorbing the acrid matter which before came in contact with the upper orifice of the stomach. In a way, not very different, demulcents sheath the inflamed or abraded surfaces of the alimentary canal, bladder, or epiglottis. See **DEMULGENTS**.

Their action has, however, been extended further; and acids, alkalines, or other acrids, have been combated by absorbents acting as chemical bodies. The former are neutralized by alkalis, calcareous and magnesian earths; the latter by acids of every kind: the acrids, if their nature is known, by their appropriate antagonists. Ancient physicians have fancifully adopted different earths to different acids. We now employ but two kinds, magnesia and calcareous earths: the former, with an acid, is slightly laxative; the latter, when neutralized, probably an astringent. Chalk or lime water are the two forms, in which this last earth is employed; for crabs' claws, crabs' eyes, egg and oyster shells, coral, and burnt hartshorn, have no other power than chalk, and are less active as absorbents. Of late, bitters have been employed with the same view; and they seem to succeed, though they probably prevent the formation of acid by strengthening the tone of the stomach, rather than correct it when formed. Yet we cannot deny some antacid power to bitters.

Alkalies act more powerfully as absorbents of acids, and they are now employed either in the common form of carbonates; in their pure state; or joined with oil in the form of soap. The pure alkali is now generally preferred.

Alkalis in the stomach are opposed by acids, and the mineral acids, as they are also tonic, are preferred. There are few instances where this state of the stomach occurs. In the advanced periods of putrid fevers, when the bile regurgitates; or, when absorbed, in jaundice, it

again mixes with every secreted fluid; and in scurvy we usually find acids necessary. In the first case, mineral acids are preferable; in the last two, the vegetable. Of the mineral acids we see no ground for preference; the oxygenated muriatic acid has not been employed freely; and oxygen, in the stomach, is certainly not salutary.

Of other acrids we have no evidence; when poisonous effluvia, particularly in cases where the infection of putrid fever has been received, and a bad taste has been perceived in the mouth, the evacuation of the stomach is the only certain remedy. Viscid phlegm sometimes loads the stomach, and medicines have been employed to "incide" and dissolve it. We know, however, no medicine that has any such power; and from its weight it cannot be very successfully carried downward, since the orifice of the pylorus is above the greater curvature of the stomach. The only remedy is to evacuate it occasionally by emetics; and, by strengthening the stomach, to prevent, at least to retard, its accumulation.

A more difficult part of the subject remains. Acids have been supposed to contaminate the blood and produce numerous diseases; for which alkalis and absorbents have been employed. Acids, however, except in children, do not extend to the alimentary canal; and we take this early opportunity of declaring, that there is not the slightest evidence of acid or any injurious substance in the vital fluid. In no instance, not even in the venereal disease, will the blood convey infection; and though what is discovered in the excreted fluids must exist in the blood, yet it is there involved, concealed, and soon separated. In short, we cannot correct acrimony in the blood; for the same power that involves it, equally involves the medicines intended to oppose it; each may again appear in the secretions.

In many diseases we perceive an acid thrown off as an offensive and injurious substance. Berthollet found it in the perspiration of gouty persons. It is more obvious in gouty chalk stones, and in the calculus vesicæ. This acid probably arises from the stomach; for, by the use of absorbents and bitters, the diseases are mitigated. They correct the forms of the disease in the first passages; and we think that they offer an instance of their power after having passed through the circulatory system, when they are again evolved in the glands. See **ANTACIDS**, **ANTALKALINES**, and **LITHONTRIPTICS**.

**ABSORBENTIA VASA, ABSORBENT VESSELS.** These are vessels which take up any fluid from the surface or any cavity of the body, and carry it into the blood. They are denominated, according to the liquids they convey, **LACTEALS** and **LYMPHATICS**; the former conveying the chyle, a milky liquid, from the intestines; the latter lymph, or a thin pellucid liquor, from the places from whence they take their origin; or any fluids that are extravasated, and convey them into the circulating blood: venal ramifications form no part of the absorbent system. See **LACTEA VASA**, and **LYMPHÆ DUCTUS**. The following kinds of absorption take place in our bodies, *viz.* the nutritious particles are absorbed from the intestines by the lacteals, which are the same *absorbents* as are in every other part; secondly, by bibulous orifices over the external parts of our bodies; thirdly, by the same kind on the internal

surfaces of all cavities, as is evident from an ascites being carried off by this absorption.

After rubbing the hand well, it hath in a quarter of an hour imbibed the ounce and a half of warm water; at the same rate, then, the whole body would have received six or seven pounds. As Dr. Hunter hath observed, this matter is demonstrated beyond a doubt by the following experiment made on a living dog: an opening was made into the cavity of his belly, and three quarts of warm water were injected and secured; in about six hours after he was examined, and not above four ounces of the water were remaining there. De Haen, who drowned dogs in coloured fluids, could find no fluid in the lungs, though the colour which it had conveyed was left.

The power of the external vessels to absorb fluids has, however, been denied by several modern authors, and positive experiments adduced where the result was very different, no diminution of the water having been found. It was supposed by the elder Monro (we ought now to say the *first* Monro,) that the power of absorption lessened with our strength. Though this may be, the fact is more certain that it increases with the wants of the system. Dr. Simson, of St. Andrew's, adduces a strong instance of a rapid decrease of the water in which the legs were bathed in a phrenitic case: and sailors, who in distress put on shirts wetted with salt water, find their thirst greatly lessened. In many cases, however, no absorption from the skin does take place. There is another power in the absorbent vessels which seems not to have been sufficiently attended to; *viz.* a selection of the substances they absorb. In general, they do not absorb gases, nor effluvia of any kind. Fluids of a narcotic nature, and almost all poisonous fluids, except the venereal poison, may be applied to a sound skin with little danger: yet we have good authority (that of Dr. Alexander) for supposing that bark and nitre may be occasionally absorbed; and we think that we have seen in a putrid sore throat, where the power of swallowing was lost, a bath made of a strong decoction of bark highly salutary. The effects of nourishing clysters are well known.

Further satisfaction on this subject may be received from what is said on the power of the external absorption of the human body by Dr. Wilkinson, in the Medical Museum, vol. ii. p. 117, &c. And with respect to absorption in the internal parts, see Dr. Hunter's Medical Commentaries; with the Observations by Dr. Garner, in the Med. Mus. vol. ii. p. 229, &c.

ABSORPTIO, ABSORPTION. See the different kinds under ABSORBENTIA VASA.

Though we are convinced by the most undoubted evidence that fluids are absorbed, we have little knowledge of the power by which this is effected. The absorption of capillary tubes is the only analogous fact, which very imperfectly assists us in the explanation. The power, however, by whatever means it is exercised, is very general: it takes place in every part of the body, and is not influenced by the weight of the atmosphere or any other evident cause: it takes place under the earth, for plants absorb their nutriment in the same way. The fetus in utero is nourished by absorption, nor is it clear that the blood from the arteries is not conveyed to the veins by a similar process.

If the power of attraction of the sides of a vessel of a minute diameter is greater than the attraction between its particles, the latter will arrange themselves round its internal surface, leaving a space in the middle which the subjacent fluids will fill. In other words, the fluid will rise in the vessel. Yet the extent of this power is limited: if in the absorbent it extends beyond the first valve, the problem is solved; for every pressure will urge the fluid onward since the valve impedes its return. In this view we dare not deny that the red veins sometimes absorb, since it is probable that they do not form continuous vessels with the arteries; that their extremities are open in cavities; that these are minute, and abundantly provided with valves. This idea is, however, on the whole, improbable; since, as the absorbent vessels are so generally diffused in the whole body, and probably through the whole of animated nature, it would appear that no other organ is designed to supply their place.

If the opinion of capillary attraction, as just now explained, be well founded, it must follow that liquids only can be absorbed: yet we find solid bones taken up and conveyed into the circulating mass. It is indeed probable that these are dissolved; but it will be obvious, that, if reduced to such a minuteness as to be suspended in a fluid; in other words, if their surfaces be increased in a ratio more than equivalent to their densities, the effects will not greatly differ. We know that in this way flint passes through the minute vessels of some plants, particularly some of the arundinaceæ, and is deposited on the epidermis, or in the cavities.

ABSTERGE'NTIA, (from *abstergeo*, to wipe off,) ABSTERGENTS, OR CLEANSING MEDICINES. Medicines, which not only by their fluidity wash off adhering matters, but such also as are supposed to do it by their power of resolving, and loosening their cohesion: hence they were considered, particularly in the Boerhaavian school, of a saponaceous nature, capable of dissolving concretions formed of earth and oil, &c., which water, simply as an abluent, cannot effect. Dr. Cullen thinks the term too general, because this power of resolving viscid substances, when used with respect to the internal parts, has generally rested upon a false supposition. They are also called DETERGENTIA. See DETERGENS.

ABSTERSIVUS, ABSTERSIVE, cleansing, wiping away; of the same import with DETERSORIUS.

ABSTINE'NTIA, (from *abstineo*, to abstain.) In a limited sense, this regulation implies moderation and temperance; and numerous are the instances in which the happiest effects have resulted from them. The abstinence enjoined by the tenets of different sects have been probably, in part, political institutions for the preservation of health. In monasteries, where active exercise is precluded, it is necessary, and in other situations often prudent. During sleep, we remain many hours without food; and animals that remain torpid for several months require no nourishment. Sedentary persons should therefore be particularly cautious in the quantity and nature of the aliment they take in. Their food should be of a limited quantity, and of a laxative nature; but not too much confined to the vegetable kingdom, as they are subject to flatulencies. Man, however, was made for variety; and the principle which

corrects the deviations from health, styled the vis medicatrix naturæ, loses its power from want of exertion; as the arm, constantly supported in a sling, would become paralytic. Even abstinence should not therefore be constantly practised; and though it should not alternate with excess, greater freedom may be occasionally allowed. The stomach, however, at times, requires rest, and it should be often many hours empty. Weak stomachs by this means recover strength, and are enabled to assimilate or discharge their crudities. Thus those who feel the immediate bad effects of excess seldom ultimately suffer: he who boasts of "never being sick or sorry" after it, finds at an early period that his constitution required some intervals of repose. The practice recommended of eating little and often is highly injurious, except in particular diseases; for food must be retained in the stomach to be digested, and, unless it is in some measure filled, the contents soon pass off. Many instances of long-continued abstinence are recorded, but generally in persons whose state resembled that of torpid animals: there is one instance of a man who employed abstinence to cure a painful disease, and he succeeded; but he felt little desire of food, and, as he had passed through the most difficult part of the attempt, obstinately refused all nourishment.

**ABSTRACTI'VIUS**, vel **ABSTRACTI'VUS**, (from *abs*, and *traho*, to draw away,) **ABSTRACTITI'OUS**. Thus the *native spirits* of aromatic vegetables were called, to distinguish them from *spirits produced by fermentation*, and are from preference drawn from those plants which abound with much volatile salt, as abstractitious spirit of scurvy-grass is better than that prepared by fermentation.

**A'BSUS**. The **EGYPTIAN LOTUS**. See **Raii Hist.**

**ABU'TILON**, (from the Arabic word **BUTILON**, yellow). An Arabic name for the **YELLOW MALLOW**. See **ALTHÆA THEOPHRASTI**, &c.

**ABYS'SUS**, **ABYS**, (*a* priv. and *βυττος*, vel *βυθος*, *gurgies profundus*, a deep whirlpool or gulf). It was a mystic term of the followers of **PARACELSUS**.

**ACA'CIA**, (from *ακαζω*, to sharpen). The **EGYPTIAN THORN**, or **BINDING BEAN-TREE**.

Several species are enumerated by botanists; but the two sorts used in medicine are,

1. *Acacia Vera*; called, by Caspar Bauhine, *acacia foliis scorpioidis leguminosæ*; and, by others, *acacia veravcl, spina Egyptiaca*. It is the *mimosa Nilotica*. Sp. Pl. L. 1506.

The **TRUE ACACIA**, or **EGYPTIAN THORN**, produces the true *gum arabic*. See **GUMMI ARABICUM**. It is remarkable that the leaves and flowers of the black thorn are purgative, though the juice from the other part is astringent.

The *acacia* used in medicine, and brought from Egypt, is a mild, subastringent, gummy substance. We receive it in roundish pieces, wrapped up in bladders; and it is of a blackish brown colour outwardly, but of a tan colour inwardly; of a hardish consistence, but not quite dry. Lemery says, that "it is made by expression out of the fruit of the Egyptian thorn, either ripe or unripe: from the ripe fruit there is a black juice, from the unripe a red or yellow one, and of a sweet scent; and that this last is what is intended by Dioscorides." It hath no smell: applied to the tongue it soon softens; is of a moderately rough but an agree-

able taste, which is followed by a sweetishness: it totally dissolves in water; so that any fraudulent addition may be discovered: rectified spirit dissolves but a small proportion, though vegetable astringents generally give out their virtue to spirit of wine as well as to water.

The **EGYPTIAN ACACIA** is now seldom used as a medicine, but is superseded by the **TERRA JAPONICA**, the production of a similar plant belonging to the same genus, whose appellation, **KATE** or **KATAA**, is not very different from that of the substance we are now considering. It was used in all cases of laxity and excessive discharges; indeed in every disease where astringents are indicated.

2. **ACA'CIA GERMA'NICA**, called also *Prunus Sylvestris*, Lin. Sp. Pl. 681. It is the **PRUNUS SPINOSA**; or **PRUNUS SYLVESTRIS SPINOSA**, foliis lanceolatis pedunculis solitariis of **LINNEUS**. **GERMAN ACACIA**, or the **GERMAN BLACK-THORN**, or **SLOE-TREE**.

The **German acacia** is the inspissated juice of the **German wild sloes**; it is of the same nature as the true sort; but in England the inspissated juice of unripe sloes of our own growth is the general substitute: it is harder, heavier, darker coloured, being almost black, and sharper tasted than the true sort. Dose ʒss.

**ACA'CIA AL'TERA TRI'FOLIA**, see **CYTISUS SPINOSUS**; for that called *gloriosa*, see **BONDUCH INDORUM**; *acacia gummi*, see **GUMMI ARABICUM**.

**ACA'CIA INDICA**. See **TAMARINDUS**.

**ACA'CIA MALABARICA GLOBOSA**. See **INTSIA**.

**ACA'CIA ORBIS AMERICANI**. See **POINCIANA**.

**ACA'CIA ZEYLOICA**. See **CAMPECHENSE LIGNUM**.

**ACA'JA**, also called *prunus Brasiliensis*. It is a large tree growing in Brasil. It produces clusters of yellowish white flowers, which are followed by yellow plums, with a large stone in them. The leaves are acid and astringent, and are an agreeable sauce with meat; the wood is light as cork, and of a red colour; the buds and tops are used as pickles. Raii Hist.

**ACAJA'IBA**, or **ACAIA'IBA**. *Arbor pomifera et prunifera Indica*. It is also called *cajum*, *cassu*, *catee*, *cajou*, *acajou*, and *kapa mata*. Sp. Pl. 548.

The **CAJOU** or **CASSU-TREE**.

There is but one species yet known, and this is the **CAJOU**, or **CASHEW-NUT**, so common in America, and in the West Indian islands. It produces its fruit in August and September; except in Brasil, where it is a native, and there it flowers in these months, and bears its fruit in December, which, when roasted, is as agreeable as an almond. If you bite the whole fruit when raw, it excoriates the mouth; therefore it must be first cut open, dipped in water, and sprinkled with salt.

The acrid oil in the shell destroys tetters, ringworms, chiques, &c. The painters use it to make their black colouring durable.

The tree, when wounded, yields a gum, which resembles the gum arabic. Raii Hist.

**ACA'JOU**. See **ACAJAIBA**.

**ACALE'PHE**, a **NETTLE**, (from *a*, negative, *καλη*, agreeable, and *αφη*, a touch), because the touch, as it hurts, is not agreeable. See **URTICA**.

There is also a fish and sea-fowl thus named.

**ACA'NOR**, a chemical furnace.

**ACA'NTHA**, (from *ακνη*, a point,) any sort of

thorn; any thing prickly, or with sharp points; also the shin or spine of the tibia; and sometimes the spina dorsa.

ACANTHA'BOLUS, (from *ακανθα*, a thorn, and *βαλλω*, to cast, or cast out). It is an instrument, described by Paulus Aegineta, for taking out thorns when stuck into the flesh. It resembles the instrument styled Volsella, for extracting bones from the Æsophagus, and any foreign matter from wounds. Celsus, viii. 30.

ACANTHA'CEOUS, (from *ακανθα*, a thorn,) ACANTHACEOUS, a botanic term applied to the plants of the thistle kind, which are prickly; also to any other prickly or pointed substance.

ACANTHA'LEUCE, (from *ακανθα*, a thorn, and *λευκος*, white). WHITE-THORN.

ACA'NTHALRUCA. See ECHINOPUS.

ACA'NTHE. The name of the artichoke in ancient authors.

ACA'NTHICE, *ακανθικη*, supposed to be the product of the carline thistle.

ACA'NTHINA MAS'TICHE. See CARDUUS PINEA.

ACA'NTHINUM (gum). See GUM ARABIC.

ACANTHINUM LIGNUM, Brasil wood.

ACA'NTHION, the HEDGE-HOG. See ECHINUS.

ACANTHUS, (from *ακανθα*, a thorn). A. Mollis, Lin. Sp. Pl. 891. Branca-ursina of the shops.

BEAR'S BREECH, or BRANK URSINE. Nat. Order *Personatae*. It is a native of the southern parts of Europe, cultivated in our gardens, flowers in June and July, and is perennial.

The roots are very mucilaginous, and the leaves are so in a lesser degree. This mucilage is demulcent, and a good substitute for the marsh-mallow. See PLICA POLONICA.

The herb-women too often sell the leaves of helleboraster, or bear's-foot, and of sphondylium, or cow's-parsnep, for the bear's breech.

ACAPA'TLI. See PIPER LONGUM. De Laet. Ind. Occid. 231.

ACA'PNON. See ORIGANUM ANGLICUM. (From *α*, neg. and *καπνος*, smoke). Applied also to honey taken from the hive without smoke.

ACA'RUS, (from *ακαρης*, small). A small insect which is said to breed in wax; also an insect in the skin like a louse. Vide PHTHIRIASIS.

A'CARON, (from *ακαρης*, small,) SMALL MYRTLE. See MYRTUS BRABANTICA.

ACA'RTUM. See PLUMBUM, N° 4.

ACA'TALIS, (from *α* neg. and *χαττω*, to want,) from the abundance of its seed: the juniper is so named. See JUNIPERUS.

ACATA'POSIS, (from *α*, non, and *καταπινω*, deglutio). See DEGLUTITIO.

ACATA'STATÆ, (from *α*, neg. and *καθιστημι*, to determine). Fevers anomalous in their appearance, and irregular in their paroxysms.

ACATH'ARSIA, (from *α*, non, and *καθαίρω*, to purge). The impurity in a diseased body not yet purged off.

ACAULIS, } of *α*, negative, and *καυλος*, caulis,  
ACAULOS, } a stalk or stem, without stem or stalk. A plant is said to be *acaulis* which has no stem, but whose flower rests on the ground, as in the carline thistle.

ACCELERATO'RES URINÆ, ACCELERATORS OF THE URINE, (from *accelero*, to hasten). Called also *urinæ stimulatōres*. They hasten the ejection of the urine and semen.

The *acceleratores urinæ* arise fleshy from the sphincter ani, and superior part of the urethra, and tendinous from the ischium. They are inserted into the corpus cavernosum, from near their beginning to a little below their union. Douglas.

Dr. Hunter observes, that the *acceleratores urinæ* are fixed to and surround the bulbous part of the urethra, meeting in a middle line or tendon at its external posterior part. They are blended, at the end of the bulbous part of the urethra, with the other muscles of the part; when these muscles are put into action, they contract upon the urethra, thereby making it narrower, and expelling the last drops of urine. The semen also meets with a fresh impulse from these muscles contracting upon it, when it is in the bulbous part of the urethra; and this seems the chief reason of its being larger in one part than another, that the semen and urine may meet with a reservoir in their passage, where they found a fresh contracting force or power to forward their expulsion.

ACCE'SSIO, (from *accedo*, to approach,) ACCESSION. The beginning of the paroxysm of an intermittent fever, &c.

ACCESSORIUS, (from *accedo*, to approach towards,) ACCESSORY. So the eighth pair of nerves is named. Willis hath given the same appellation to some branches from the eighth pair of nerves. They arise by several filaments from both sides of the *medulla spinalis* of the neck. Having advanced to the first vertebra, each is fixed to the back side of the *ganglion* of the *nervus suboccipitalis*, or tenth pair; then again run upwards into the *cranium* by the great occipital hole, communicate with the ninth and tenth, return out of the *cranium*, and in their passage join the eighth pair; afterwards turning backward, and perforating the *musculus sterno-mastoideus*, terminate in the *trapezius*, having first sent some branches to the rhomboides.

ACCESSORIUS, (*musculus*). Vide FLEXOR DIGITORUM ACCESSORIUS, and LONGUS PEDIS.

ACCESSORIUS-SACRO-LUMBARIS, vel LUMBALIS. See SACRO LUMBARIS.

ACCIPITER, (from *accipio*, to take,) THE HAWK. In chirurgical language, it is the name of a bandage which was put over the nose; and it was so called because it resembled the claw of the hawk.

ACCIPITRINA, (from *accipiter*, the hawk,) HERB HAWKWEED. Because hawks were said to scratch it, and apply the juice to their eyes to prevent blindness. The flax weed has also the same appellation. See HERACIUM and SOPHIA.

ACCLIVIS, (from *ad*, and *clivis*, an ascent). See OBLIQUUS ASCENDENS ABDOMINIS.

ACCOUCHEMENT, (Fr. *lying in*, delivery,) and hence the practitioners have been styled Accoucheurs.

ACCRETIO, (from *ad*, and *cresco*, to grow to,) ACCRETION, GROWTH, and NUTRITION. See NUTRITATIO; also a growing together, as the fingers or toes to one another.

ACEPHALOS, (from *α*, negative, and *κεφαλη*, a head,) applied to monsters born without heads, in-

stances of which occur in Schenkii Paræus, Wolfius, Mauriceau, &c. These are collected by Wepfer, and modern collections contain similar instances.

A'CER, the MAPLE-TREE, (from *acer*,) because of the sharpness of its juice.

The great maple-tree, falsely called SYCAMORE, is the pseudo platanus. Lin. Sp. Plant. 1495. It is also called *platanus tragi*.

The maple is a large tree, common in England, but a native of Austria and Switzerland.

It is not much in use as a medicine, though its juice, if drunk whilst fresh, is said to be a good antiscorbutic.

All its parts contain a saccharine fluid; and if the root, trunk, or branches, are wounded in the spring, a large quantity of liquor is discharged, which, when inspissated, yields a brown sort of sugar, and a syrup like the molasses. Large quantities of this sugar are obtained from the trees in New England and Canada, and is much used in France, where it is commonly known by the name of *saccharum Canadense*, and *saccharum acernum*, MAPLE-SUGAR. It has been supposed that all Europe might be supplied from the maples of America, but the sugar is coarse and ill-tasted.

A'CERATOS, (from *a*, *non*, and *χεραι*, *to mix*). Hippocrates applies this term to the unmixed, uncorrupted humours of the body.

A'CER VIRGINIANUM, odoratum. LIQUID AMBER. See LIQUID AMBER.

ACERBITAS, (from *acer*, *sharp*,) ACERBITY, SOURNESS.

ACE'RBUS, SOUR, HARSH; or a sourness with aspergency; also bitter.

ACE'RIDES, *Ακνιδες*, (from *a*, negative, and *κνος*, *wax*). Plasters made without wax.

ACERO'SUS, (from *αχυρον*, *chaff*). It is used to signify that sort of brown bread which is made without first separating the bran; and in botany it is applied to a leaf which is surrounded at the base by branny scales.

A'CESCENT, substances which readily run into the acid fermentation; sometimes applied to fluids in which this fermentation has commenced.

ACES'TIDES, (from *ακν*, *a point*). The names of the chimneys of the furnaces where brass was made. They were narrow at the top to receive the fumes of the melting metal, and to collect them, that the cadmia might be produced more abundantly. Also the roof of the furnaces in which copper is fused: they are closed so as to detain the corpuscles which fly off.

ACE'STIS. See BORAX.

ACE'STORIS, (*ακεστορις*, from *ακεσμαι*, *to cure*). It strictly signifies a FEMALE PHYSICIAN, and is used for MIDWIFE. Hence curable diseases are called ACESTÆ.

ACE'STRIDES. MIDWIVES.

ACETA'BULUM, (*κοτυλη, κοτυληδαν, οξυβαφος*,) is a large cavity in a bone, to receive the convex head of another, for the advantage of a circular motion. The large cavity in the os coxendix is thus named, which receives the head of the os femoris. This cavity is called the cup, from its likeness to an ancient vessel in which vinegar was brought to the table, and thence named acetabula, from *acetum*, *vinegar*, and *tabula*, *a table*. This derivation seems very probable, as *οξυβαφος*,

which is the same measure as the ancients called *acetabulum*, seems to be derived from *οξος*, *vinegar*. The *acetabulum*, which receives the head of the thigh-bone, called also *costyle*, is formed by the juncture of the os ilium, ischium, and os pubis; the edge of this cavity is called supercilium, and is very prominent on the upper part; the cavity is deeper on the upper and back part than on the lower and fore part. In the natural state, this cavity is increased by an additional elastic circle, which is united to its edge; it yields easily both ways to any pressure, but recovers itself when the force is removed.

*Acetabulum* also signifies a sort of glandular substance found in the placenta of some animals. See COTYLEDONES.

The ancient measure thus named was about the one-eighth of a pint.

ACETABULUM, scc CRASSULA.

ACETA'BULUM MAR. MIN. See ANDROCASE.

ACETA'R, (from *acetum*, *vinegar*,) a salad of crude vegetables, to be eaten with vinegar, oil, and salt.

ACETARIA, PICKLES. The unripe melons, young cucumbers, the seeds of the nasturtium, are preserved with vinegar and rendered warmer with garlic and shallot, under this name. The East-India mango is a plum highly flavoured with garlic; and, in imitation of this flavour, cabbage shred in slips, broccoli heads, onions, &c. with garlic, and Cayenne pepper, are sold under the title of Pickalella. See CONDIMENTS.

ACETA'RIMUM SCORBU'TICUM. A kind of pickle, in which Dr. Bates advises scorbutic patients to dip their victuals before they eat it. It is thus made: ℞. Fol. cochlear. marin. ℥ iij. sacchar alb. ℥ vj. sal cochlear. ℥ i. bene contund. simul. et adde succ. aurant. ℥ vj.

ACETO'SA. See ACETOSELLA.

ACETO'SELLA, so called from the acidity of its leaves. The plants of this acid nature employed in medicine belong to the genus oxalis L. and are the O. Acetosella Sp. Pl. 620, O. Corniculata 623; O. Cernua Willdenow, vol. ii. p. 717. This genus of plants, by the labours of Jacquin and Thunberg, is considerably augmented; and the last edition of Linnæus, by Willdenow, contains 83 species, the greater number of which are subacid, containing, in modern chemical language, super-oxalate of potash, viz. the alkali more than saturated with the oxalic acid. Some of these species are more acid than others: the common wood sorrel is the least so. Some species of the rumex have had the same appellation, (*Rumex Acetosa* L. Sp. Pl. 481,) as the leaf stalks are sour; and the same acidity occurs in the leaf stalks of the rheum compactum, a plant nearly allied to the docks. The juice of sorrel is sometimes used as an agreeable refrigerating drink in fevers, and sometimes the leaves are boiled in milk, to form a pleasant whey. Externally, they are thought to promote suppuration, particularly in indolent serofulous humours. The seeds are slightly astringent; and indeed we seldom find astringency in any part of a plant, but we discover acidity in some other. The expressed juice is now never used, and the conserve is rejected from the dispensatories: it is pleasing as a conserve, but nearly inert as a medicine. The salt of lemons, as it is called, is only the salt of wood sorrel, and sometimes supposed to be cream of tartar, with

a little sulphuric acid. It is chiefly used for taking out the stains of ink from linen; and, were the muriatic acid added, the salt would be scarcely inferior in this power.

A great part of the acid of sorrel may be obtained in the form of a concrete salt, which is more acid than that of tartar, more easily soluble in water, and less, if at all, purgative; the wood sorrel yields near one-hundredth part of the weight of the fresh leaves.

Different methods have been proposed to separate the mucilage of the expressed juices, which is the great impediment to their crystallization. The method of Stahl, and the elder chemists, consisted in repeated affusions of alcohol. The process of Scheele is now generally adopted: it consists in combining the acid with calcareous earth, which forms a neutral nearly insoluble in water: this neutral may then be repeatedly washed, and the vegetable acid recovered by the addition of the sulphuric. This was the process recommended for the salt of lemons, and is the method by which Mr. Coxwell's concrete salt is prepared. But he wisely, we have been told, directs the chalk to be combined with the acid in the country; and it is imported in the form of the earthy salt; so that the fruit is not liable to injury by packing, and the inconveniencies of a sea voyage.

**ACETUM, VINEGAR.** This is the second state in which the saccharine juices of vegetables appear in consequence of a spontaneous fermentation, in a heat of about 80° of Fahrenheit. In the first it becomes a wine; but a saccharine substance seems to be the principle, from which spirit is mostly formed, and mucilage that of vinegar. In the general subjects of fermentation they are united, and the acetous follows the vinous state. Should gluten predominate in the mixture, ammonia is soon discoverable, and the liquor turns putrid. In the acetous fermentation, much air is absorbed, which is apparently oxygen. See **FERMENTATION**.

Acetous acid may be formed in other ways, independent of fermentation. It is separated from many vegetable substances by distillation. Water and carbonic acid gas are at the same time raised, and charcoal deposited. The action of nitric acid on many vegetable substances, particularly gum and farina, also produces it with the same residuum of charcoal, and exhalation of carbonic acid gas and water. This acid also appears in some changes where putrefaction is apparently going on; as in the animal economy, where the urea is separated from the urine. Acetated lead produced from this acid, and the metal, forms a curious subject of speculation. By means of the lead it appears to regain its original state of a saccharine matter; for this substance may be fermented, again produce a vinous spirit, and ultimately again vinegar. See **Neumann's Chemistry**.

Vegetable liquors, in proportion to the quantity of their saccharine parts, ferment into a weaker or stronger kind of wine; a second fermentation forms vinegar.

When malt liquor becomes acid, it is called *allicar*, **ALLEGAR**. It is not so proper either for medical use, or preserving pickles, as the wine vinegar; for it abounds too much with mucilage, which is productive of many disadvantages; yet this is the only vinegar that we procure in England.

If vinegar be distilled with a heat not exceeding that of

boiling water, it yields first a phlegmatic liquor (which is a spirit slightly vinous); then a slightly acid one, which is succeeded by stronger acids, till the matter remaining becomes thick as honey; if now it is urged with a greater heat, an empyreumatic oil ascends, and a penetrating acid spirit, tainted with the ill smell and yellow colour of the oil; and at last there remains a black coal, which, when burnt into white ashes, yields a considerable proportion of fixed alkaline salt.

By distillation, vinegar is separated from its mucilage, tartar, &c. Its specific gravity is then reduced from 1.0135 or 1.0251 (for it generally varies) to 1.0005. By boiling a few minutes, it keeps a long time with little change.

The stronger and more spiritous the wine, the stronger is the vinegar into which it is converted. Geoffroy says, that vinegars made of the German and French wines saturate from one-fortieth to one-twelfth of their weight of fixed alkaline salt.

Vinegar is mixed with the mineral acids by some fraudulent dealers, and the vitriolic, as the cheapest, is most commonly employed. The slightest portion may be detected, by adding a solution of muriated barytes, or a larger, by a saturated solution of chalk. In either case, a white sediment is deposited. Lead is sometimes accidentally present, and may be discovered by the liquor probatorius. See **LIQUOR PROBATORIUS**.

The fermentation which changes wine into vinegar gives the latter several properties extremely different from those of the former, which are well known. Vinegar is ultimately decomposed by nitric acid, or by fire, when combined with fixed alkali to repress its volatility. It is then found to consist of carbone, hydrogen, and oxygen, but the proportions are not known. It is concentrated by freezing; but the purest acetous acid freezes at about 22° of Fahrenheit, and by distilling it when combined with powdered charcoal. For its affinities, see **ELECTIVE ATTRACTIONS**.

Vinegar dissolves *animal earths*, if not very much mixed with gelatinous matter; the *earth of alum*, and *calcareous earths*; it *oxidates several metallic substances*, as *zinc, iron, copper, nickel, tin, and lead*. It combines with earths, alkalis, and metallic oxides; it dissolves the *vegetable inspissated juices*, and extracts the *virtues of many plants*; to many of which it seems to impart additional power, particularly to the onion tribe. In *inflammatory and putrid diseases*, in many instances, its efficacy is considerable: in *ardent fevers* it is an useful *antiphlogistic* and *sudorific*: in *putrid disorders* it is a preservative and restorer. *Fainting, lethargic, and hysterical paroxysms* are much relieved by it, if applied to the nose and mouth; even in many instances more than by volatile alkaline spirits, or fetid gums. In the *miliary fever* it is a powerful assistant. The vegetable acid has a peculiar power in *restoring sweetness to putrid bile*; and that obtained from the fresh vegetable fruits is more useful than the mineral acids. Besides, when a putrid colluvies is lodged in the first passage, this acid gently tends to solicit its discharge by stool; an advantage not to be expected from the mineral tribe.

**EXTERNALLY APPLIED**, vinegar is a powerful resolvent and relaxant. When applied to any sensible membrane, it acts as an astringent; and, more or less diluted with water, is an excellent gargle for an inflamed throat,

and for an injection to moderate the fluor albus. See ACIDA.

It has been lately recommended in burns, whether there is a loss of substance or not. The burnt part is to be bathed in vinegar, till the pain ceases; then a common poultice with finely powdered chalk strewed on it is to be applied. This poultice at first must be changed every four hours, and afterwards two or three times a day. When there is no loss of substance, the vesicles are filled with a coagulated fluid, under which the skin soon heals. As a cooling application in bruises, its use is well known; and it is frequently applied in its cold state to the nose in cases of hæmorrhage. In mænorrhagia, particularly the profluvia after parturition, applied cold to the loins and abdomen, it is very serviceable. Chilblains are also often relieved, corns and galls softened by it.

An imprudent use of vinegar is not without considerable inconveniences; large and frequent doses produce leanness and an atrophy; when taken to excess, to reduce a corpulent habit, tubercles in the lungs and a consumption have been the consequence: young children, old people, those whose circulation is languid, vital heat defective, and digestion weak, should perhaps be sparing in its use.

The dose, according to the different circumstances of the case requiring it, and the constitution of the patient, may be from  $\frac{3}{4}$  ss. to  $\frac{3}{4}$  iij.

See the Dictionary of Chemistry, translated from the French of M. Macquer, edit. 2, article VINEGAR. Cullen's Mat. Med. Chaptal's Chemistry, vol. iii. 268. Thompson's Chemistry, 2d edit. Parkinson's Chemical Pocket-book.

ACETUM DISTILLATUM, seu Sp. Aceti. DISTILLED VINEGAR. ACETOUS ACID.

Distil wine vinegar with a gentle heat as long as the drops fall free from an empyreuma.

The first pint that is drawn off is a weak vinous spirit, and should be taken away, another receiver being placed for the acid. Malt vinegar, however strong, is improper for distilling, because it so readily receives an empyreumatic taste from the mucilage which it contains; a circumstance to which the best wine vinegar is subject, if more than about two-thirds is drawn over. If given, in the quantity of two or three ounces in a day for some time after bleeding, and purging where necessary, it has been recommended in maniacal cases. When vinegar is concentrated, it creates an appetite; hence *Acetum Esurinum*.—LYTHARGYRITIS. See PLUMBUM, N° 2.—PROPHYLA'CTICUM (see PROPHYLACTIC) is thus made.  $\mathcal{R}$  flor. lavend. et rorism. fol. rutæ, absinth. salviæ, menth. aa m. i. aceti vini cong. i. infund. in B. A. per 8 dies.  $\mathcal{R}$  hujus tinct.  $\mathcal{H}$  i. camph. 3 iij. m.—Acetum proph. also called the VINEGAR OF THE FOUR THIEVES; for, during the plague of Marseilles, four persons, by the use of it, attended many of the sick unhurt; under the colour of their service, they robbed the sick and the dead: one of them being apprehended, saved himself from the gallows by discovering this remedy.

In the foreign pharmacopeias there are many preparations in which vinegar is the menstruum; and luxury has introduced many as sauces, or to add a flavour or poignancy to sallads. With these last we have no business, and need only remark, that when the object is to give

an additional warmth or stimulus, they are not misapplied. Vinegar of horse-radish and elder (Plenck Pharmac. chirurg.) are chiefly useful as cosmetics. Vinegar of rue (idem) is supposed to be highly antiseptic; but the most useful acetum is the camphorated. A drachm of camphor is dissolved in ten ounces of good vinegar (id.); and a preparation not very dissimilar is recommended in mania by Mr. Pargeter. Numerous preparations under the title of aceta prophylactica, occur in the foreign dispensatories, which consist only of different aromatics infused in vinegar, differing from the fancies of the prescriber, but scarcely varying in the intention or effects.

Vinegar, we have said, may be concentrated by cold, and by distillation from powdered charcoal. What is called the ACETIC ACID is vinegar, not only more concentrated, but somewhat different in its properties. It certainly possesses a larger proportion of oxygen, as will be evident from its preparation, which consists in distilling vinegar from its combination with metallic oxyds, chiefly from copper; and that this method not only enables it to rise without the usual proportion of water, but imparts oxygen, is evident from the same effect being produced by adding sulphuric acid to the union of vinegar with soda; when a part of the mineral acid is decomposed. The acetic acid is peculiarly volatile and pungent, the most carefully ground glass stoppers being unable to confine its fumes. Glass and gold can alone retain it without being injured. Its specific gravity is 1.0626. The salts produced by this acid are called acetats, while those made with the common acid are styled acétites. Though these salts differ somewhat in their properties, we have no evidence of their differing in their medical virtues. See Fourcroy Connoissances, v. viii. Annales de Chymie, xxvii. 299.

ACHA'HI. See AQUA ALUMINOSA under ALUMEN.

ACHANACA, an Indian plant much used by the natives as a remedy for venereal complaints: its genus is unknown.

ACHE, a pain: in old authors the name of the *apium palustre*: the *smallage*.

ACHIA, ACHIAR, ACHAR, the buds of the bamboo tree pickled with spices and other ingredients, imported from India to Holland in earthen vessels: they partake of the virtues and inconveniences of PICKLES. See CONDIMENTS and ACETARIA.

ACHICOLUM. The *fofnix*, or *sudatorium*, SUDATORY, of the ancient baths, which was a hot room to sweat in, called also *architholus*.

ACHILLE'A. The *achilleas* take their name from ACHILLES, because with this he is said to have cured Telephus. Linnæus uses the word *achillea* as the generic term for yarrow, milfoil, or sneezewort. For an account of the different species see AGERATUM. The name also of the red gum, now called dragon's blood.

ACHIL'IS TENDO, see TENDO ACHILLIS.

ACHIMENUS. A genus of plants formed by Vahl among the didynamia angiospermæ, in the family of the personatæ. It consists of a single species only, figured in Rheed's Malabar, ix. tab. 87, growing in Cochin China, called by Loureiro *dicera*. It resembles wood sorrel in taste, and is eaten in sallads as well as dressed.

**ACHIO'TE.** The red grains of achiotl made into lozenges.

**ACHIOTL:** also the *bixa ovedii*, *daburi*. A sort of *orleana*, growing in New Spain and Brasil, from the *bixa orellana* Lin. Sp. Pl. 730. The tincture from the fruit used in chocolate is thus made: take the grains when ripe, infuse them in hot water; the sediment is made into cakes, and is used as a paint for the face. The *roucou*, which the Indians call achiotl or *urucu*, the Dutch *orleane*, and we *roucou*, is a meal or flour of a seed from the Leeward islands and the isle of St. Domingo: these seeds are of a vermillion colour. The *roucou* is made in these islands, as we make starch. Choose the *roucou* of the deepest violet colour, and very dry. Its chief use is among the dyers. See *ORLEANA*.

**A'CHLYS.** A DIMNESS of sight, (from *αχλος*, darkness or cloudiness). It also signifies a small scar or mark over the pupil, of a light blue colour. It is usually synonymous with *caligo cornea*, or blindness from opacity of the cornea. See Cullen's Nosology. It is the *Leucoma nephelium* of SAUVAGES, and is described as a speck of the cornea, somewhat pellucid, which occasions objects to appear as if seen through smoke, or a cloud. By inspection obliquely it is discovered to be different from the opacity of the aqueous humour, accompanying some diseases of the eye. This disease consists in an obstruction of the lymphatic arteries of the cornea, and is often the consequence of more active inflammation. Any powder, mild and soluble, thrown into the eye; a drop or two of emetic wine, or of tincture of opium, will remove it; but in children it vanishes spontaneously.

A very complicated ointment is recommended by Mr. Bell for this complaint, and for diseases of the eyelids, copied from Pellier. We shall not transcribe it, since, from frequent experience, we have found equal parts of unguentum mercuriale and saturninum as effectual. In fact, it is only a combination of mercury, zinc, and lead, though operose and inelegant; the balsam. Peruv. adding nothing to its efficacy. The ointment of M. de Gravers has no lead, but the zinc supplies its place, and the efficacy is increased by the addition of one-fifth of the compound tincture of benzoin. See *ALBUGO OCULORUM*, and also Wallis's *Nosologia Methodica Oculorum*.

**A'CHNE**, *αχνη*. CHAFF or the FROTH of the SEA. Hippocrates expresses by it a whitish mucilage observed in the eyes of patients who have fevers: also a white mucus in the fauces thrown up from the lungs. Besides these it signifies LINT. See *CARBASUS*.

**ACHOAVAN.** A kind of chamomile mentioned by Prosper Alpinus: its species is not known. V. *CHAMOMILE*. Avicenna seems to have meant by it the marum.

**A'CHOLOS**, (from *a*, neg. and *χολη*, bile,) applied to animals supposed to be without bile.

**A'CHOR**, *αχαρ*, qu. *αχνη*, (from *αχνη*, bran; so called from the branny scales thrown off). *Lactum*: *abas*, *acores*, *cerion*; *favus*. The *crusta lactea* of authors, and in England the SCALD HEAD. Trallian says, that it is a sore on the outside of the head, full of little perforations, which discharge a humour like ichor. He adds, that the *cerion* resembles an achor; but that the mouths of the perforations are larger, re-

sembling the cells of a honey-comb, whence the name; the matter is also nearly of the consistence of thin honey. When these diseases spread, the serum which oozes out dries, and forms a scab. It is, however, in general, only an obstruction in the circulation of the bulbs of the hair, and sometimes of the sebaceous glands.

Dr. Willan, in his description of different kinds of pustules, defines the achor, a pustule of intermediate size between the phlyzadium and psydacium, which contains a straw-coloured fluid, having the appearance, and nearly the consistence, of strained honey. It appears most frequently about the head, and is succeeded by a dull white or yellowish scab. Pustules of this kind, when so large as nearly to equal the size of phlyzacia, are termed *ceria*, or *favi*, being succeeded by a yellow, semi-transparent, and sometimes cellular scab, like a honey-comb.

The *achor* differs from the *favus* and *tinea* only in the degree of virulence. It is called *favus* when the perforations are large; and *tinea* when they are like those which are made by moths in cloth: but generally by *tinea* is understood a dry scab on the hairy scalp of children, with thick scales and an offensive smell; when this disorder affects the face, it is called *crusta lactea*, or MILK-SCAB. Mr. Bell, in his Treatise on Ulcers, says, that the *tinea capitis* and *crusta lactea* may both be reduced to the same species of herpes, viz. the *herpes pustulosus*, (which see,) they being naturally the same, differing only in situation; the *tinea* is on the hair scalp, and the *crusta lactea* on the face. Dr. Cullen improperly places this disease under *ULCUS*; as a synonyme; where also he places the *CRUSTA LACTEA*; but the whole class locales is very carelessly arranged. When it happens to children, if in other respects they are healthy, the best treatment, besides keeping the belly moderately lax, is cleanliness and a moderate diet; an issue may be made and continued till the disorder is cleared and the strength of the constitution established; the hair must be kept short, and the head washed with soap-suds. Some instances of this sort are very difficult of cure, and attended with violent itching, a pale countenance, &c.; but still the same method generally succeeds in all the species and degrees of virulence. Small doses of calomel may be given as an alterative rather than as a laxative, and the vinum antimon. in such doses, at proper intervals, as the stomach will easily retain. Though in general it is a local disease, yet the constitution is sometimes in fault, and internal remedies should not be neglected. When hastily and imprudently repelled, also, disagreeable consequences have ensued.

Externally, washing with soap, particularly the black soft soap, and occasionally using the ung. e pice, will succeed; but, in the more inveterate cases, the unguentum ad scabiem of Banyer's Pharmacopœia Pauperum, (quod vide,) lowered with an equal part of axyngia, is necessary. Should this fail, the only remedy is to pull out each hair, by tweezers, or to put on a pitch cap, which when taken off draws them out at once—a cruel practice, but sometimes indispensable. A wash, consisting of a solution of corrosive sublimate, in the proportion of ten grains to a pint of water, has sometimes succeeded. The unguentum picis cum sulphure of the Pharmacopœia of Guy's Hospital is often

advantageous; but the head must be constantly close shaved, and an oil-skin cap worn, which, alone, will sometimes cure the complaint. This ointment is composed of half a pound of tar, half an ounce of wax, and two ounces of flour of sulphur. More lately, shaving the head, and keeping up a steady pressure by means of slips of sticking plaster, have appeared more effectual than the oil-skin cap.

Among the ancients, Aetius, Ægineta, Trallian, Oribasius, Galen, &c. treat professedly on these disorders: amongst the later authors, Heister and Turner may be consulted, with the still later writers, as Bell, in his Surgery, and his Treatise on Ulcers, p. 376; Moss on the Management of Children, &c.; White's Surgery, p. 69.

A'CHY, (αχυ,) a species of cassia growing in Arabia, called also *δαφνιτης*.

ACIA, a method of healing wounds among the ancients, which is now not easily understood. It is most probably derived from acu, and may be only the twisted suture.

ACICULARIS, (from *acicula*, a pin or needle,) ACICULAR, shaped like a small needle. The trivial name for a species of scirpus.

ACIDA. ACIDS, (from *acesco*, to sharpen.) Acids form a species of salts, exciting upon the organ of taste the sensation called *sour*; which may be regarded as synonymous with acid. Every substance is called acid which gives the impression above specified to the taste, will change certain blue vegetable colours into red, as the juice of turnsole, syrup of violets, &c. and will, usually, effervesce with alkalis; we say usually, because this property is not general; for the carbonic acid, and almost all weak acids, cannot be distinguished by this property; and the purest alkali, or what is called caustic or deaerated, combines with acids without effervescence. By a variety of experiments in modern chemistry, acids are found to consist of different substances: to the name of one they give the term *oxygen*; and to the other *radical*; the former considered to be the *acidifying* principle, the latter the *acidifiable* base. They further prove, that the oxygenous principle, in all the variety of acids, is universally the same; and that acids themselves only vary on account of the different radicals with which that principle is combined. Chemists have also altered the terms, in order to express the degrees of power acids possess; the weaker they express by the termination *ous*, the stronger by *ic*, added to the base or radical; as sulphurous, sulphuric; carbonous, carbonic, &c.; except the muriatic and nitrous acid; for the lower order of the former, they say *muriatic*; for the higher, *oxygenated muriatic*; taking the appellation from the acid, and not from the base.

Acids are animal, vegetable, and mineral. The vegetable are the native, as the juice of lemons, &c.; or the product of fermentation, as vinegar and tartar. The mineral are those of sulphur or vitriol, nitre, and common salt. The animal acid is obtained from ants, and some other insects, in considerable quantities; it is also contained in human fat, and in the suet of animals that ruminate; and an acetous fermentation is sometimes excited in some of the animal secretory organs, forming a kind of animal vinegar; in this way the urea of the urine is produced. See ADIPS.

A vague, volatile, and liquid acid is in all parts of the earth: uniting with various substances, it forms different fossils. Except in the essential salts of vegetables or in tartar, acids are rarely found in a solid form.

There is great analogy betwixt acid and cold. The spirit of nitre increases the cold of ice. Acid and cold alike preserve from putrefaction, by increasing the cohesion of the component parts of the respective bodies. Strong acids, and excessive cold, it is true, when applied to the flesh of living animals, mortify them; but this mortification differs greatly in its nature from that produced by fire, and by alkaline salts. South winds favour, but north winds check, the progress of putrid disorders.

Acids differ in their specific gravity when compared with water.

The acid of vitriol, as 18 to 10

Nitre 14 to 10, some say 15 to 10

Sea salt 12 to 10

Vegetables 10 plus to 10.

This difference shews that some acids are more tenacious of water than others. If the weaker acids are used, you must pour on more of them to the same quantity of alkaline salt to saturate it; yet the salt will have only attracted the same weight of acid from each.

Acids differ in their colour: for the *vitriolic* is quite pale; the *nitrous* a dark yellow, frequently fuming, and sometimes of an orange red; the *marine* a pale golden colour. If bottles containing these three acids are stopped with cork, the cork is soon tinged, by the vitriolic acid, with a black colour; by the nitrous, with a yellow; and by the marine, with a whitish one. The vitriolic acid emits no visible vapours in the heat of the atmosphere, but imbibes moisture from it; the nitrous and muriatic emit copious corrosive fumes; the nitrous, yellowish red; and the muriatic, white fumes.

For the virtues of the vegetable acid, see ACETUM.

The mineral acids, when intimately joined with vinous spirits, produce effect so similar to those of the vegetable class, that their properties, as medicines, are almost the same. In other respects, the effects of all the kinds of acids are similar.

Acids gently irritate and contract our fibres when taken in a dilute state, and thus corroborate; they resist a putrid tendency, and powerfully oppose putrescence when actually existing: by the irritation they promote various secretions; they excite an appetite, and aid digestion; their efficacy in fevers of every kind is not exceeded by any thing in use, nor equalled for their general safety, where causes so widely opposite produce such similar complaints: in some instances of coughs and asthmas, in consequence of irritation, their efficacy is singular: if the vegetable acid is made use of, the breathing is never disordered by it, though in some instances the mineral acids may offend. In dysenteries, and in diarrhoeas, produced by unripe fruits, the fossil acids allay the fermentation in the bowels; and when a putrid coluvies in the primæ viæ is the cause, they will be a proper remedy. By their sedative quality, hæmorrhages are restrained; and as bitters are neutralised by vegetable acids, so the excess and acrimony of the bile are allayed by their use.

Acids, astringents, and bitters, have a great affinity

with each other. By a mixture with each other they lose their properties. Vegetable acids lessen the astringent power of galls on leather, &c. The mineral acids have a contrary effect. Bitters, both animal and vegetable, are neutralised by vegetable acids, less perfectly by those from the mineral kingdom. See Lavoisier and Chaptal's Elements of Chemistry. Dictionary of Chem. Neumann's Chem. Works. Percival's Med. Essays.

Vegetable acids correct the deleterious effect of most, if not all, narcotic plants; but injure the phlegmatic habit, where the circulation is languid, the bile defective, or the digestion naturally weak.

ACIDITAS, (from *acesco*, to *sharpen*,) ACIDITY, also *acor*. Diseases from this cause are frequent.

The seat of acidity in our bodies, as a disease, is principally the stomach and the small intestines. An acid acrimony is never sensibly prevalent in the blood; though it sometimes appears in the urine.

An acid acrimony may arise either from too great laxity and debility of the organs of digestion, or from an excess of acescent food. When the digestion is imperfect, an acidity is the consequence, though no such process as fermentation has preceded. The food of children is for the most part of the vegetable kind, and readily turns sour in the stomach, if the body be any way disordered; hence most of their disorders are accompanied with the evident signs of acidity, as green stools, gripes, &c. Many assert a prevailing acid to be the cause of all diseases in children; but acidity in their stomach is more often an effect than a cause of their complaints. It is not acidity, but its excess that injures.

The redundant acid in the *primæ viæ* is known by the *sourness of the eructations*, the *frequent cardialgia*, in the stomach, *flatulence*, and *spasms in the intestines*; the belly is costive, and the nourishment is unduly supplied, a paleness becomes general in the skin, an itching comes on, pustules appear, and a train of nervous symptoms soon succeeds. Indeed, in all diseases peculiar to children, there are, for the most part, symptoms of an excess of irritation: the pulse sometimes beats one hundred, or one hundred and twenty in a minute, the stomach is disordered, the vessels of the skin are contracted, and epileptic or convulsive symptoms appear.

Infants are frequently swept off by this disorder. Among adults, the weakly and sedentary are the only subjects of it, except among the poor, whose scanty supplies reduce them to this unhappy state.

The cure, when adults are the subjects, consists of a diet fitted to oppose this faulty habit; animal food and vegetables of the aromatic kind: these, with moderate exercise at proper intervals, will often succeed with warm tonics. Absorbent medicines may palliate symptoms in the stomach and intestines, but the *limatura ferri* will most conduce to an effectual and lasting cure. Children should be exercised more, and fed less than is usual. Antimonial emetics, repeated at intervals of two or three days, until the more disagreeable symptoms abate, are highly useful. Small doses of *p. rhei*, with *magnes. alb.* so as to keep the belly soluble, is better than more active purging; and small doses should be given frequently. Indeed, in some cases, small doses of fixed or volatile

alkali, particularly *aqua ammoniæ*, have been highly beneficial, and warm stimulant plasters, applied to the umbilical region, have added to these advantages. Acidity is not peculiar to children, nor does it always depend on the nature of the food. It is a mark of a disordered digestion from many different causes. Curdled milk, ejected, is supposed to be a decisive proof of an acid stomach. This, however, is by no means the case: for the stomach of an infant will curdle milk, when it will not, to the nicest test, discover the slightest particle of acid. A gouty habit, and the pregnant state, will always bring it on; and, in many constitutions, food of every kind will soon become acid, for reasons that we cannot understand. All that can be known is, that the principles of the vegetable acid, for of this nature is the morbid acid of the stomach, are found in food of every kind, and that, when their union is destroyed in the first periods of digestion, a new compound takes place. Perhaps this always occurs, and the acid is again enveloped or forms a part of another compound, by a subsequent operation. Calcareous and magnesian earths, therefore, only palliate the complaint: the cure depends on strengthening the stomach. As palliatives, in the chronic cases of acidity, lime-water is one of the best. In the pregnant state, *aq. ammoniæ puræ* is preferable.

See Van Swieten's Commentaries on Boerhaave's Aphorisms. *Medicamentorum Formulæ*, Dris. Hugh Smith. London Practice of Physic, edit. 6. Armstrong on Diseases fatal to Infants. Moss on the Management of Children, &c.

ACIDULÆ, (from *acidus*, *sour*.) MINERAL WATERS that contain a brisk spirit, when unaccompanied with heat, are thus named: but if they are hot also, they are called *thermæ*. In Paracelsus, *Fontale acetosum* is of the same import.

As to the antiquity of their use, see Galen, Cœlius Aurelianus, Pliny, &c. who speak also of their virtues.

Hoffman and many authors highly extol them, whilst others observe that a pure water, on account of its simplicity, such as that from Malvern and Toplitz springs, is to be preferred both for drinking and for bathing; and that these may be well supplied by distilled rain, or any other water that is soft and pure. Objectors allege, that the medicinal qualities in these waters only quicken their operation as water, but contribute nothing further, and that solutions of the same materials are of equal efficacy: to which the best reply has been, that the mineral contents are often volatile, and more subtle than art can produce; and that, when the powers of nature are expiring, experience proves their efficacy by their success as a last resource.

From the qualities of their contents their use is easily determined. See *AQUÆ MEDICINABLES*.

Bleeding, or purging, or both, are frequently prescribed before the use of mineral waters; but, except a plethora attends, they are unnecessary. As these waters are designed to act, so rest or exercise must be advised: rest and a cool situation favour their diuretic tendency; exercise and a warm air determine them to the skin; with temperance and moderation in the regimen, these are the principal directions on which success depends.

Their brisk sparkling property is owing to the quantity of uncombined carbonic acid gas which they possess;

and indeed to this, perhaps, is owing their chief use as medicine. To increase this gas when defective, or to communicate it where it is totally wanting, see Dr. Priestley's directions for impregnating water with fixt air.

ACIDULOUS, SUBACID.

ACIDUM PINGUE, a fancied acid which Meyer substituted to explain the causticity of lime, which Black attributed to the loss of its fixed air or carbonic acid.

ACIDUM FORMICÆ. *Formic acid*. See FORMICA.

ACIDUM ARSENICUM. ARSENIC ACID. This is produced by distilling six parts of nitrous acid, from one of the calx of arsenic.

ACIDUM ÆTHEREUM.

ACIDUM ALUMINOSUM.

ACIDUM CATHOLICON.

ACIDUM PRIMIGENIUM.

ACIDUM SULPHUREUM.

Acidum vitriolicum, vel sulphuris.

ACIDUM MURIATICUM. Olim. Spiritus Sâlis Glauberi. See MARI'NUM SAL.

ACIDUM NITROSUM. See NITRUM, N° 5.

ACIDUM VITRIOLICUM. Olim Oleum Vitrioli; called also *Stagma*. See SULPHUR and VITRIOLUM VIRIDE, and also A'CIDA.

ACIDUM VITRIOLI VINO'SUM, i. e. Æther vitriolicus. See ÆTHER.

ACIES, (from *ακη*, a point). STEEL. See CHALYBS.

ACINAFORMIS, (from *ακιναις*, a scymitar, and *forma*, shape,) applied to leaves, one of whose edges is sharp and convex, and the other straight and thick, like a Persian scymitar.

ACINE'SIA, (from *α non*, and *κινεω*, to move). A privation of motion.

A'CINI, (from *ακη*, a point). The distinct component parts of the fruit of the mulberry, blackberry, and raspberry.

ACINIFORMIS.

ACINO'SA TU'NICA. } The coat of the eye, called uvea, or posterior lamina of the iris; because the ancients, who dissected brutes, observed that in them it was usually the colour of an unripe grape. See UVEA.

ACINOS, (from *ακη*, a point;) so called because its branches are prickly. See BASILICUM.

ACINUS. Properly a grape, but is applied to other fruits or berries that grow in clusters, as elder berries, privet, ivy, &c. These are distinguished from baccæ, or berries that grow single, as those of the laurel. But *acinus* is also used for the stone of the grape; hence U'VE EXACINA'TÆ, grapes that have their stones taken out.

The glands which grow together in clusters are called by some *âcini glandulosi*.

A'CINUS. See STAPHYLOMA.

ACIPENSER, Lin. The sturgeon. The species introduced into the *Materia Alimentaria* and *Medica* are the *A. sturio*, *huso*, and *ruthenus*, Lin. The roes are salted and dried, and the flesh pickled. These, which may rather be styled condiments than aliments, will be considered in their proper places. Isinglass is prepared from the roes of each species, but that from the *A. huso* is preferred. See ALIMENTS, CONDIMENTS, and ISINGGLASS.

ACMA'STICA, (from *ακμαζω*, to flourish). See SYNCHUS.

ACMASTICOS, (*ακμαζω*, *vigeo*), a species of fever described by Actuarius, as follows:

"Fevers from putrefaction are continual or intermittent: of the former some are called *isotoni*, or *acmastici*, which, during the whole course, are at the same pitch; others are called *ephacastici*, or *anabases*; these proceed and increase to their time of solution; a third sort called *paracmastici*, which diminish by degrees till they cease." See FEVER.

A'CME, (from *ακμη*, a point). THE HEIGHT OF A DISEASE. That state of a thing in which it is at its utmost perfection. It is also a term in gymnastics, expressing the highest pitch of exercise.

ACME'LLA, a plant growing in Ceylon, the *verbena acmella* Lin. 1271; but a similar plant, the *sigesbeckia orientalis*, has been employed. It is commended in nephritic disorders by Linnæus, but is rarely used.

A'CMO. See CORALLIUM RUBRUM.

ACNE, (from *ακνη*, chaff). A small purple or hard tubercle on the face is thus called, covered with a branny scale.

ACNE'STIS (from *α negative*, and *κναιν*, to scratch). That part of the spine which reaches from betwixt the shoulder blades to the loins. This name seems only applicable to quadrupeds, because they cannot reach it to scratch.

There is a herb to which this name is given, but the real plant has not been determined.

ACO'E, (*ακουω*, audio). See AUDITUS.

ACQUITUS, HONEY, (from *α non*, and *κοινη*, sediment). See MEL. Pliny speaks of it by this name, because it has no sediment.

A'CON, an instrument used in the ancient exercises; like the discus, or quoit.

ACON'DYLUS, (from *α priv.* and *κονδυλος*, a joint). Applied to a flower whose stalk is not divided by joints.

ACONE, (*ακων*, a hone,) MORTAR, or rather a hard stone, on which to levigate; more generally, a WHETSTONE.

ACON'ION, (from *αωνη*, a hone,) an ancient Greek name of a medicine prepared by levigation; probably a collyrium, or some form of powders for the eyes.

ACONITIFOLIA, (from *aconitum*, wolf's-bane, and *folium*, a leaf). See ANAPODOPHYLLON.

ACONITON, (from *α neg.* and *κονια*, lime or plaster). Not plastered. This word is applied to vessels not lined within.

ACONITUM; also called *Camarum*, *Canicida*, *Cynocotantum*. Various derivations are given by etymologists; as, 1st, *ακων*, a whetstone or rock, because it grows on bare rocks. 2dly, *α negative*, and *κονια*, dust, because it grows without earth. 3dly, *ακων*, *ακη*, dart, because they poison darts therewith. 4thly, *ακονισμα*, to accelerate, for it hastens death.

WOLF'S-BANE.

The MONK'S-HOOD, or COMMON WOLF'S-BANE, of which Dr. Storck speaks so much in favour, is the *ACONITUM NAPELLUS* Lin. Sp. Pl. 751, Willden, G. 1062, Sp. 9. N. Ord. multisiliquæ. It is cultivated in our gardens as an ornament; but is spontaneously produced in Germany, and some other northern parts of Europe. Some authors have supposed that Storck employed the *A. camarum*: in fact, however, he used the *A. neomontanum*, and mistook it for the *A. na-*

pellus. The different species have been mistaken for each other, but all seem to possess the same properties.

The expressed juice of the fresh herb was made into an extract by a gentle evaporation, then for internal use the following powder was directed:

℞ extract. aconit. gr. ij.

Sacchar. alb.—5 ij m. f. pulv. subtil.

In several instances, this was given from gr. vj. to 3 ss. three times a day, with the happiest success. Its chief sensible effect was its exciting a copious perspiration.

The cases in which Dr. Storck succeeded by the use of the above powder were, an *inveterate gonorrhœa*, *obstinate pains* after intermittent fevers, *tophi* and *nodes*, *scirrhus tumours*, *indurations of the parotid glands*, *spina ventosa*, *itch*, *amaurosis*, *gouty* and *rheumatic pains*, *convulsive disorders*, and an *anchylosis*. Some have given it in tincture, made by adding one part of the dried leaf to six of spirits of wine; the dose, 40 drops. But it has often been given from one grain, gradually increased to ten, for a dose: indeed Stoll and some others carried it much further.

A person who had eaten a small quantity of monk's-hood was presently attacked with a sensation of tingling heat in the tongue and jaws, and the teeth seemed as if they were loose, and the face as if it was swelled. This tingling sensation gradually spread all over the whole body, particularly to the extremities; the knees and ankles lost their strength, and frequent twitching of the tendons came on; soon after a sensible check to the circulation of the blood through the limbs was felt; at length a giddiness supervened; then a mist seemed to collect itself before the eyes; in the ears was a humming noise, the senses failed; the eyes and teeth were fixed, the nose contracted, breathing short, and cold sweats were perceived on the hands, feet, and forehead. All these symptoms followed in less than two hours from the time of eating the salad, in which the monk's-hood unfortunately was mixed. His friends forced down into his stomach a quantity of oil and water, and afterwards carduus tea, by which he vomited; these were repeated so as to encourage a thorough discharge from the stomach, and, in the intervals, a few spoonfuls of a stimulating cordial were given: and thus he soon recovered.

Some writers say, that the napellus is not poisonous in Sweden, Poland, &c.; but it should be noted, that the napellus, which is not poisonous, is the *aconitum lycoctonum* Lin. Sp. Pl. 750. See Wilmer's Observations on the Poisonous Vegetables of Great Britain. Storck, de Aconito, and the Article VENENUM.

A'COPA. *Acopon*, (*a non*, and *κοπος*, labour). At first this word signified the quality of the medicines to relieve pain, stiffness, and other ill effects of excessive weariness; but, afterwards, it implied soft, easy medicines, prepared with little difficulty. It is also the name of the *trifolium paludosum*.

A'COR, (from *aceo*, to be sharp). SOURNESS, ACIMONY, particularly an acid acrimony in the stomach. See ACIDITAS.

ACO'RDINA. INDIAN TUTTY.

A'CORES. See ACHOR.

A'CORI, (RAD). THE GREATER GALANGAL ROOT, (from *a neg.* and *κορα*, the pupil of the eyes,) because

this root was thought injurious to the eyes. See GALANGA.

ACO'RIA, (from *a neg.* and *κορεω*, to satiate). INSATIABILITY. Sometimes it signifies a good appetite, or digestion.

ACORI'TES VINUM, a wine made of the acorus and liquorice roots, each eight ounces; of wine, six gallons; infused cold for six months.

ACORN, the seed of the oak used as an astringent. See OAK.

A'CORUS, CALAMUS VE'RUS. See CALAMUS AROMATICUS.

A'CORUS ADULTERINUS. See IRIS PALUSTRIS.

A'CORUS ASIATICUS. See CALAMUS AROMATICUS ASIAT.

A'COS, (*ακοσμαι*, sano). A REMEDY.

ACO'SMIA. IRREGULARITY, or disturbed state of things, particularly of the critical days of fevers, as *κοσμος* meant their regular order; called also *madises*, *madrotes*. Bald people are called *acosmoi*, because they had lost their greatest ornament. Blanchard says it is an ill state of health, joined with a loss of colour in the face.

ACOTYLE'DON. Applied to seeds when they are without cotyledons.

ACO'USTICA, medicines against deafness (from *ακουα*, to hear). But no internal medicines of this kind are known.

ACRA'L. See SATYRIASIS, and FUROR UTERINUS.

ACRA'PALA, a Greek word for medicines against a surfeit or drunkenness, from *a non*, and *κραιπαλη*, crapula.

ACRA'SIA, INTEMPERANCE, (from *a negative*, and *κεραννυμι*, to mix). This word, implying wine unmixed with water, signified excess in eating, drinking, venery, &c. By Hippocrates, and some others, it signifies imbecility. By physicians, it means the predominancy of one quality above another, either with regard to artificial mixtures, or the humours of the body.

ACRA'TIA, (from *a negative*, and *κρατ*, strength). See IMBECILLITAS.

ACRATI'SMA, a BREAKFAST. The derivation of this word is the same as that of acrasia, because the wine used on this occasion was not mixed with water. A breakfast among the old Greeks consisted of a morsel of bread steeped in wine.

ACRATOME'LI, (from *ακρατον*, unmixed wine, and *μελι*, honey). See MULSUM.

A'CRE, (*ακρος*, extreme). See NASUS.

A'CREA, also ACROTE'RIA, (from *ακρος*, extreme,) the EXTREMITIES, i. e. the legs, arms, nose, and ears. Coldness in the extremities, not easily removed, is a bad presage in fevers.

A'CRIDÆ, (from *acer*, sharp). ACRID MEDICINES.

Acrids are substances of a penetrating pungency: applied to the skin, they inflame it; chewed, they promote a discharge of the saliva; and snuffed up the nose, they provoke sneezing.

The first class, as mustard, horse-radish, scurvy-grass, &c. give out their properties by distillation. The 2d, viz. the greater celandine, pyrethrum, &c. by infusion. The 3d, neither by infusion nor distillation, as happens with the arum, dracunculus.

The general effects of acrid medicines are to stimulate the solids. In leucophlegmatic habits, they are

powerful expectorants, deobstruents, diuretics, and emmenagogues; and, if the patient is kept warm, they are good diaphoretics.

In constitutions disposed to inflammation, or where there is already a degree of irritation, where the juices are too thin and acrid, or the viscera not sound, these medicines aggravate the disorder.

The trouble which acrid medicines give to the stomach, is that on which their virtue frequently depends.

ACRIFO'LIUM, (from *acris*, sharp, and *folium*, a leaf). Any prickly-leaved plant.

ACRIMO'NIA, ACRIMONY, (from *acer*, sharp). This term is applicable to any substances that produce particular sensations from the actions of that stimulus which they possess, and which we express by the different terms, sharpness, eagerness, tartness, acid, alkali, &c.; but it is more strictly applicable to some states of the humours in the human body, as acrimony of the bile, and other fluids, which are, by the laws of the animal economy, constantly thrown out of the machine; for, except when in a morbid state, the fluids are free from all acrimony. Acrimony is often accused as a cause of various diseases, without a distinct idea of its nature, or indeed a sufficient evidence of its existence. Modern pathologists are more moderate; yet we hear of gouty and scrofulous humours, of cancerous and other acrimonies which affect the skin. Nothing is more evident, than that the two former are diseases of the solids, and that the depositions are the effects, not the cause, of the disease. In the two latter, acrimony may be suspected. A cancer often naturally heals, and soon affects other parts: repelled from the glands, it falls on the joints, the head, and other organs. The cutaneous diseases of children shew marks of acrimony, since, when they take place, they improve the general health; and issues, in such cases, often inflame violently. When bile is absorbed in jaundice, there is an itching on the skin; and in those who have injured their stomachs by spirituous liquors, eruptions are often extensive and inveterate.

A'CRIS, (*ακρίς*). The top of a mountain; also the sharp extremities of fractured bones. It is also a locust, i. e. the insect so called, and which the Africans, and some others, commonly eat.

ACRIS'SIA, ACRI'TUS, (*α non*, and *κρίσις*, judico). It is when a distemper is in so uncertain and fluctuating a condition, that it is difficult to pass a right judgment on it. Blanchard.

ACRIVIOLA, (*acer*, sharp, and *viola*, a violet). See NASTURTIIUM INDICUM.

ACROBYSTIA, (from *ακρος*, extreme, and *βυω*, to cover). See ACROPOSTHIA.

ACROCHORDON, (from *ακρος*, extreme, and *χορδή*, a string). A name given to a sort of warts, from their hanging by a string or neck. Wiseman calls them pensile warts. See VERRUCÆ. Celsus observes, that if they are cut out, they leave no root, so do not grow again.

ACROLE'NION, (*ακρον*, the extremity, and *ωλενη*, the cubit). See OLECRANON.

ACRO'MION, } (from *ακρος*, extreme, and *ωμ*, the  
ACRO'MIUM, } shoulder). See SCAPULA, 2.

ACROMPHA'LION, (from *ακρος*, extreme, or the tip, and *ομφαλος*, navel). The tip of the navel, or the middle of the navel.

A'CRON, in general, means the top or summit, hence, in a medical sense, it is the best of its kind. In botany, it is the top or flower of thistles.

ACRO'PATHOS, (from *ακρος*, extreme, and *παθος*, a disease). It literally signifies a disease at the height; or, a disease which affects any superior part of the body. Hippocrates applies it to the internal orifice of the uterus, when affected; to occult cancers, and to cancers on the surface of the body, to distinguish them from internal ones.

A'CROPIS, (from *ακρος*, extreme, and *οψ*, the voice,) when the voice cannot be exerted. An inarticulation of the voice, from an imperfection in the end of the tongue. It is once used adjectively in the spurious works of Hippocrates, but no where determined in its signification and orthography.

ACRO'PSILON, (from *ακρ*, the extremity, and *ψιλος*, naked). The extremity of the glans when naked.

ACRO'SAPES, (from *ακρος*, extreme, and *σηπω*, to putrify). Galen means by this term, easy of digestion. This mode of speaking originates from a dogma of physicians, that digestion was performed by a certain degree of putrescency; for often names originate from a false principle, and are retained by authors who do not acquiesce in that principle.

ACRO'SPELOS, (from *ακρος*, extreme, and *πελος*, black). A name of the WILD OAT-GRASS, or BROMUS STERILIS. See ÆGYLOPS.

ACROTE'RIA. See ACREA.

ACROTERIA'SMUS. The amputation of an extremity. (From *ακραίηρια*, extremities, and this from *ακρ*, summus).

ACROTHY'MIA, } (from *ακρος*, extreme, and  
ACROTHY'MION, } *θυμος*, thyme, from being the colour of thyme). See NÆVUS. A sort of wart described by Celsus as hard, rough, with a narrow basis, and broad top; the top is of the colour of thyme, it easily splits, and bleeds. This tumour is called *thymus*.

ACT. MED. An abbreviation of Thomæ Bartholini Acta Medica et Philosophica Hafniensia.

ACT. PHILOS. and TRANSACT. PHILOS. The Philosophical Transactions.

ACT. REG. SC. The Histories and Memoirs of the Royal Academy of Sciences at Paris.

ACT. S. R. Acta Societatis Regiæ, or Philosophical Transactions, London, 4to.

ACTÆA. Herb CHRISTOPHER. A poisonous plant, which has been formerly used externally as a repellent, and internally by the ancients in female diseases. It is not now employed. The *A. spicata*, Lin. is the species that has been preferred, which belongs to the multisiliquæ and ranunculaciæ of Jussieu.

A'CTE, (*ακτη*, from *αγω*, to break,) ELDER, so called from its being easy to break. See SAMBUCUS.

A'CTINE, (from *ακτιν*, a ray; from its radiated ramifications). See BUNIAS.

A'CTIO, (from *αγω*, to act,) vel FUNCTIO; also FACULTAS.

The actions or functions of the body are divided into the vital, natural, and animal.

The VITAL FUNCTIONS, or ACTIONS, are those which are absolutely necessary to life, as the actions of the heart, lungs, and arteries. On the action and reaction of the solids and fluids upon each other, depend the

vital functions. The pulse and respiration are the external signs of life. Vital diseases are all those which hinder the influx of the venal blood into the cavities of the heart, and the expulsion of the arterial blood from them.

The NATURAL FUNCTIONS are those which are instrumental in repairing the several losses which the body sustains; for life is destructive of itself: its very offices occasion a perpetual waste. The manducation, the deglutition, and digestion of food, the separation and distribution of the chyle, and excrementitious parts, &c. comprise natural functions, as by these our aliment is converted into our nature. They are necessary to the continuance of our bodies.

The ANIMAL FUNCTIONS are those which we perform at will, as muscular motion, and all the voluntary actions of the body; they are those which constitute the sense of touch, taste, smell, sight, hearing, perception, reasoning, imagination, memory, judgment, and other affections of the mind. Without these a man may live, but not so comfortably as with them.

The SEXUAL ACTIONS are those of the organs of generation of either sex.

PRIVATE ACTIONS are such as regard particular parts.

PUBLIC ACTIONS are those which are performed for the sake of the whole body; such is the action of the stomach in digesting the aliment, &c. These are called functions.

But each part hath an action peculiar to itself. Thus the offices performed by the muscles, vessels, glands, and viscera, are called their *respective action*. See Professor Whytt's Treatise on Vital Motions.

ACTON, a town near London, where is a well that affords a purging water; from a gallon of which Dr. Rutty got 340 grains, or five drams, two scruples, of sediment by evaporation: of this, five drams and twenty-one grains were vitriolated magnesia, or vitriolated lime, called formerly nitrum calcarium, which took forty-eight times its own weight of water to dissolve it; and nineteen grains of aluminous earth. This is esteemed one of the strongest purging waters near London. It is drunk from one to three pints in a morning. Monro's Medical and Pharmaceutical Chemistry. See *AQUE CATHARTICÆ AMARÆ*.

ACTUALIS, ACTUAL, (from *αγω*, to act). This word is applied to any thing which acts by an immediate power inherent in itself: it is the reverse of POTENTIAL; thus, a red-hot iron or fire is called an *actual* cautery, in contradistinction to cauteries, or caustics, that have the power of producing the same effect upon the animal solids as actual fire: these last are called *virtual* or *potential* cauteries. Boiling water is actually hot; brandy, producing heat in the body, is potentially hot, though of itself cold.

This is the medicinal sense of the word; in logic and metaphysics it is used otherwise.

ACTUATIO, ACTUATION, (from *αγω*, to act). That change wrought on a medicine, or any thing taken into the body, by the vital heat, which is necessary to make it act, and have its effect.

ACUITIO, (from *acuō*, to quicken). This is applied often to medicines which are added to others weaker than themselves, in order to increase their me-

dicinal action; as vegetable acid may be sharpened by the addition of mineral acid, or mild purgatives may be quickened by the addition of small doses of those which are more powerful.

ACULEI, (dim of *acus*, a point,) the prickles and thorns on vegetables.

A'CULON, or ACULOS, the fruit or acorn of the *ilex*, or scarlet oak, (from *α non*, and *κυκλω*, to roll round): this is called aculon therefore, because its fruit is not involved in a cup or sheath, like the others.

ACUPUNCTURA, (from *acus*, a needle, and *pungo*, to prick,) ACUPUNCTURE. Bleeding performed by making many small punctures with a silver needle on the part affected. This method is practised in Siam, Japan, and other oriental nations, on all parts of the body; and employed in head aches, lethargies, convulsions, colics, &c. See Phil. Trans. No. 148. In some parts of America this practice is also in use, according to the accounts given in Dampier's Voyages, though as an ornament rather than a remedy.

A'CUS, (from *acuō*, to sharpen,) a NEEDLE. This instrument is necessary in confining the lips of wounds, taking up and tying blood-vessels, &c. They are of various forms, according to the use for which they are designed: it is of considerable importance that they should be sharp and made of good metal that is well tempered. See Bell's Surgery, vol. i.

A'CUS PASTORIS. See SCANDIX.

A'CUS MOSCHATI. See GERANIUM MOSCHATUM.

ACUSTICUS, (from *ακουω*, to hear, belonging to hearing). It is applied to the auditory nerve, and to medicines or instruments used to assist, preserve, or recover hearing.

ACUTENA'CULUM, (from *acus*, needle, and *teneo*, to hold). Heister calls the *portaignuille* by this name; it is a handle for a needle, to make it penetrate easily when stitching a wound. Bell's Surgery, i. 16.

ACUTUS, (from *acuō*, to sharpen). In botany, it is applied to a leaf ending in an acute angle, but not so taperingly as the acuminate leaf.

ACUTUS MORBUS. An *acute disease* proceeds quickly to its termination, and always is attended with danger. Though there are diseases without danger, of a short duration, so are distinct from the *acute*, as an *ephemeris*, &c. In general, this term is applied to fevers; for apoplexy is never styled an *acute disease*, though its duration is short. *Acute diseases* are the opposite to *chronic*, which are slow in their progress, and not immediately dangerous. Wallis's Sydenham, 1.

ACY'ISIS, (from *α non*, and *κυω*, to conceive). In Vogel's Nosology it is a defect of conception, or barrenness in women. ACUTUS has a similar meaning.

ACY'RUS, (from *α non*, and *κυρος*, authority). A term for the herb German Leopard's bane, so named from the little note it used to be thought of in medicine; though lately highly recommended as tonic antiseptic, and considered in Germany, as a valuable remedy in putrid fevers. See ARNICA MONTANA.

ADAMITA, (from *adamas*, a diamond,) is properly the stone in the bladder; *adamitum*, the lithiasis, or disease called the stone. See CALCULUS.

A'DAMUS. The philosopher's stone. The alchemists say that it is an animal, and that it has carried

its invisible EYE in its body from the moment they were first united by the Creator. It is also called *Aquila*, *Philosophorum Lapis*, *Basaliscus*, *Benedictus*, *Boritis*, *Gryphus*; by way of eminence, *Antidotus*. This stone, the greatest object of alchemy, is a long sought for preparation; which, *when found*, is to transmute or exalt impurer metals, as tin, lead, and copper, into gold and silver. Authors who have written on this stone call *sulphur the maritus*, or husband; and mercury, the *uxor*, or wife.

ADAMI POMUM, the convex part of the thyroid cartilage of the larynx.

ADANSO'NIA, from *Adanson*, the name of the person who first described the *Æthiopian* sour gourd. See BAOBAB.

ADARCE, (from *a* neg. and *δερμα*, to see). A saltish concretion, found about the reeds and grass in marshy grounds in Galatia, which prevents the herbs upon which it forms from being seen; it is also called *calomohanus*, or *calomochmus*. It is lax and porous, like bastard sponge. It is used to clear the skin in leprosy, tetter, freckles, &c. Dr. Plott gives an account of this production in his *Natural History of Oxfordshire*.

ADARTICULA'TIO, (from *ad*, and *articulus*, a joint). See DIARTHROSIS.

ADCHER, the name given by Avicenna and Serapion to the *schananchus*, or camel's hay, q. v.

ADCORPORA'TIO, (from *ad*, and *corporeo*, to incorporate). ADCORPORATION, or uniting in one body.

ADDEPHAGIA, or ADEPHAGIA, (from *αδν*, abundantly, and *φωγειν*, to eat). INSATIABILITY, a voracious appetite. It is the *Bulimia Hæluonum*. See BOULIMUS.

ADDITAME'NTUM, (from *addo*, to add,) the same as *epiphysis*. A small bone joined to a larger, by means of a cartilage; any additional substance; also a suture. The large epiphysis of the ulna is called *additamentum necatum*.

ADDITAMENTUM CO'LI. See APPENDICULA VERMIFORMIS.

ADDU'CENS, (from *adduco*, to draw forward). Vide ADDUCTOR OCULI.

ADDU'CENS HUMERI. See PECTORALIS MAJOR.

ADDU'CTOR, A LEADER TO, (from *adducere*, to move or bring towards). A name of several muscles.

1. ADDU'CTOR AD MI'NIMUM DI'GITUM. It rises from the unciform process of the carpus towards the annular ligament, and is inserted into the whole length of the inside of the metacarpal bone of the little finger.

2. ADDU'CTOR AU'RIS. It is a common muscle, being a part which Spigelius calls *quadratus buccæ detrahens*; from its insertion is a fleshy fibrous elongation implanted into the root of the ear.

3. ADDU'CTOR DI'GITI MI'NIMI PEDIS, called also *transversalis pedis plantæ*. It rises from the fourth metatarsal bone, and going over the knobs of the toes, runs to the external sesamoid bone. Douglas says, it brings the third and fourth lesser toes nearer the other two, and the great one.

4. ADDU'CTOR FE'MORIS PRI'MUS, vel LO'NGUS. It rises from the os pubis, next the pectinæus, above

the gracilis; which turning into a compact fleshy belly, it begins to be inserted tendinous about the middle of the linea aspera, being continued down upon the same five or six inches, sending out a tendon which joins in with that of the fourth head.

5. ADDU'CTOR FE'MORIS SECU'NDUS, vel BRE'VIS. It arises from the os pubis, immediately under the gracilis, by a broad tendinous, but chiefly fleshy, beginning, and is inserted into the linea aspera, from a little below the lesser trochanter, to the first insertion of the last described muscle.

6. ADDU'CTOR FE'MORIS TE'RTIUS, vel MA'GNUS. It arises lower down than the former, from the outer edge of the os pubis and ischium, and, running obliquely towards the trochanter minor, is inserted near the glutæus maximus. This and the next muscle are described as one muscle, by Albinus and Winslow, under the names of ADDU'CTOR MAGNUS FE'MORIS, and *le troisième muscle du triceps*. It is also called *triple musculus*.

7. ADDU'CTOR FE'MORIS QUARTUS. It arises from the protuberance of the ischium, and the adjoining interior part of that bone, by a tendinous or fleshy origin. It is inserted by a round and a long tendon into the upper and rough part of the inner and lower appendix of the os femoris, being affixed to that bone a little above the condyle, as also to some part of the linea aspera. The above four muscles of the thigh are described by Dr. Hunter, &c. as one, and under the name of *TRICEPS*, which see. Their use is to adduce, or move, the thigh inwards, according to their different directions, and bring them to each other.

8. ADDU'CTOR OCULI, also called *adducens* and *rectus internus*. It rises tendinous and fleshy from the edge of the hole in the sphenoid bone that transmits the optic nerve, and is inserted by a thin tendon into the tunica sclerotica, where it respects the great canthus. It brings the eye towards the nose. Some call it *bibitorius*, as it directs the eye towards the glass in drinking.

9. ADDU'CTOR PO'LLICIS MANUS AD IN'DICEM. Riolan calls it *antithenar*. It rises from the fore part of the metacarpal bone of the fore finger, joins with the anterior portion of the flexor secundi internodij pollicis, and is inserted with it into the sesamoid bone. See ADDU'CTOR INDICIS, N° 4.

10. ADDU'CTOR PO'LLICIS PEDIS. It rises by a long thin disengaged tendon from the os calcis, under the tendinous part of the massa carnea, from the os cuboides, the os cuneiforme medium, and from the upper part of the os metatarsi of the second toe; it is soon dilated into a pretty large belly, and is inserted in the external os sesamoides of the great toe. Douglas says it brings the great toe near its next.

ADE'CTOS, (from *a* neg. and *δακνω*, to bite). An epithet given to medicines that relieve from the biting sense of pain, by removing the uneasiness caused by stimulants; whence Celsus calls them *lenia*.

ADELPHIA, ADELPHIXIS. Analogy and relation, applied by Hippocrates to diseases.

ADEMONIA, } (of *a* neg. and *δαμων*, a genius,  
ADEMONIA, } or divinity, or fortune). Hippocrates uses this word for the uneasiness, restlessness, or anxiety, felt in acute diseases, and some hysteric fits.

A'DEN, A GLAND. See GLANDULA. Sometimes it signifies the same as *bubo*. Blanchard.

ADENDENTES, (from *aden*, a gland, and *edo*, to eat). Ulcers which eat and destroy the glands. See PHAGADENA.

ADENES CANADENSSES. See BATTATAS CANADENSIS.

ADENIA. A genus of Hexandria monogynia. One of its species, viz. the *A. venenata*, an Arabian tree, is poisonous; and the *capparis spinosa* is supposed to be an antidote to it. Forskhal.

ADENOIDES, (from *adn*, a gland, and *ειδος*, a form). GLANDIFORM, or like a gland. This word also is used for the *prostate*, q. v.

ADENOSUS ABSCESSUS. A hard tubercle, resembling a gland, difficult to be resolved.

A'DEPS, FAT, called also *pinguedo*, *axungia*, *butyrum*, *arvina*, *arabus*, &c. Fat is a condensed oily juice, contained in that part of the cellular membrane called *membrana adiposa*. When superfluous, and found in the upper eye-lids of children, it was called *axirnach*. In the young fœtus is scarcely any fat; the omentum seems only to contain a jelly; but in the more advanced stage, fat begins to appear. When the child is born, and during a few years after, it hath much fat immediately beneath the skin; in men the fat is most abundantly spread on the glutei muscles: it is separated from the blood by a glandular secretion.

There is also a fatty substance, butter, obtained from the milk of animals, by agitating its oleaginous part, separated by standing, in an instrument called a churn: called also *alumbair*.

From the most accurate analysis of Crell, it appears that fat is a kind of oil, or butter rendered concrete by an acid. This, the sebatic acid, exists ready formed in suet, two pounds affording somewhat more than seven ounces. By adding alkalis to animal fat, a soap is formed; which is decomposed by alum. We thus obtain the sebate of potash, which is decomposed by the sulphuric acid. When chemically examined, it is found to resemble very nearly the acetous acid. Six parts of fat contain nearly five of carbon, and one of hydrogen, with some of the acid, not decomposed; nor does it yield so much oxygen and nitrogen as the fleshy parts. The accumulation of fat is a process not completely understood; nor are its uses known. It contains, as we have seen, the acetous acid; and, on the whole, seems a morbid secretion when in a large quantity, since it predisposes to many diseases, and is itself a disease. We should suspect that it was designed to inviscate a proportion of the acetous acid when in excess; since it is favoured by indolence and inactivity, when we find acids morbidly accumulated in different secreted fluids, as in the urinary and arthritic calculi. It has been supposed to be the accumulation of a stock of nutriment, to supply accidental and temporary deficiencies, or to cover morbid acrimony in the fluids. It must be allowed, that, from want of food, the fat wastes and is absorbed; but we are yet to learn, that fat persons can bear famine better and longer than lean ones. At the same time, it is observed that the fat is not so much wasted in those who are worn down by the gradual decay of a hectic; who, from a scirrhus œsophagus, or a cancer of the throat, die from inanition, as in dropsies, where the appetite continues with little diminution. It

has also not been ascertained that it imparts any heat to the body, or the viscera, which the omentum covers.

Berthollet discovered, in animal substances, what he considered as a peculiar acid, and he called it the *zoonic acid*. It had the smell of broiled flesh, was liquid in a temperate heat, more volatile than boiling water; formed soluble salts with barytes, strontian, lime, and alkalis; precipitated the nitrat of lead and the acetite of mercury; deposited charcoal, and was, in time, decomposed. Subsequent inquiry has, however, shewn that this is not a new acid, but the acetous acid, containing some animal matter in solution. It is of more importance, since it shews the acetous acid in a new compound in the animal machine.

Fat differs from suet principally in the great quantity of water it contains, which, being slowly evaporated, is converted into a sebaceous substance. Steatoms, which sometimes are found in the *membrana adiposa*, are of a very different nature.

The human fat does not become fluid when Fahrenheit's thermometer rises to the ninetieth degree; but when it begins to putrify, it easily, and with a small degree of warmth, runs into oil.

In cetaceous fishes the fat is thin as oil; in animals that live on herbage only the fat is harder, and yet harder in those that chew the cud.

The Arabians used a great variety of fats in medicine; but to relax the parts to which they are applied, and to stop perspiration, are their chief virtues. In the present practice, three kinds are employed, and these only on account of their different consistence; they are the fat of *vipers*, *hog's lard*, and *mutton suet*. The fat of geese is now wholly rejected. Their use is chiefly external. As to viper's fat, it is well supplied by the oil of olives; for it does not appear that animal fats, and insipid, flavourless vegetable oils, of similar consistence, differ in their effects when used externally: in other instances, there seems to be a greater similarity between animal and vegetable fats, or insipid oils, than between any other similar animal and vegetable substances, such as gums and animal jellies: animal fats, in their resolution by fire, yield neither the peculiar stench, nor much, if any, of the volatile alkaline salt, which substances completely animalised afford. Mutton suet is sometimes taken internally as a mild nutrient; occasionally, as a demulcent in diarrhœas, when the mucus of the intestines is abraded; but it seems to possess no very considerable power in either respect.

Animal fats are not soluble in rectified sp. vin. nor in water. When scented with essential oils, the latter may be totally extracted by digestion in rectified spirit, and, in a less degree, by water. Fats may thus also be freed from their ill smell; and those that are become rancid may be made sweet.

Animal fats preserve steel from rust better than vegetable ones; mutton suet prevents brass from growing ill coloured, longer than any other fat; and if a little camphor and white lead are added, these ends are still better answered.

The fat of vipers being separated from their intestines, may be melted before a gentle fire, and run through a thin linen cloth.

See Haller's Physiology, on the cellular membrane.

ADEPTA PHILOSOPHIA. ADEPT PHILOSOPHY.

It is that philosophy, whose end is the transmutation of metals, and an universal remedy. The professors of this philosophy are called ADEPTI, adepts. Paracelsus calls that *medicina adepta*, which treats of the diseases that are contracted by celestial operations, or communicated from heaven.

ADHATO'DA. The MALABAR NUT. Referred by Lin. to the genus *justicia*; not employed in modern practice, and seemingly useless.

ADHESIO, (from *ad*, and *hæreo*, to cleave to,) ADHESION. In medicine, a term used for two parts sticking together, which are naturally separate.

If any of those parts in the thorax or belly that lie in contact inflame, they commonly grow together. The lungs very frequently adhere to the pleura.

On this subject see Dr. Fleming's treatise on adhesions, or accretions of the lungs; or an abstract from it in the *Med. Mus.* vol. i. To this head must be referred the modern improved method of healing wounds as is said, "by the first intention:" the lips are brought together, and thus adhere. See VULNUS.

ADIANTHUM, ADIANTUM, (from *α*, non, and *διανω*, to grow wet,) so named because the leaves are not easily made wet. MAIDEN-HAIR. Also called *polytrichon* and *polytrichum*, (from *πολυς*, much, and *τριξ*, hair,) expressive of a capillary herb.

Two species are only employed, viz. *A. capillus Veneris*, Lin. Sp. Pl. 1558, and *A. pedatum*, 1557. From the latter, the French prepare their sirop de capillaire, which they flavour with orange-flower water: a proportion of honey, it is said, is usually added. It acts chiefly as a demulcent, sheathing the inflamed and irritable epiglottis.

ADIAPHOROUS, a spirit distilled from tartar; said, by Mr. Boyle, to be neither acid, vinous, nor urinous.

ADIAPNEU'STIA, (from *α*, neg. and *διαπνεω*, to perspire.) IMPEDED PERSPIRATION; which was considered by the ancients as the primary cause of fevers, from what they termed *vaporosa et fuliginosa effluvia*, not being permitted to pass through the cutaneous pores.

ADIAPTO'TOS, (from *α*, neg. and *διαπιπλω*, to stumble or slide.) The word signifies firm; but in medicine it is the name of a remedy against the colic, of stone-parsley, henbane-seed, white pepper, &c. formed into an electuary.

ADIARRHŒA, (from *α*, neg. and *διάρρῃω*, perfluo, to flow out or through.) It signifies a total suppression of the necessary evacuations from the bowels.

ADIBAT. See ARGENT. VIVUM.

A'DICE, (*αδίκηω*, to hurt.) See URTICA.

A'DIPIS SUP'LLÆ PRÆPARA'TIO, olim AXUNGIE PORCINÆ CURATIO. See ADEPS.

ADIFOCIRE. The modern appellation of SPERMACETI, q. v.

ADIPO'SÆ ARTERIÆ, et VENÆ. They are branches from the phrenitic arteries, which are spread on the fat that covers the kidneys, from which the blood is returned by the veins. See CAPSULARES ARTERIÆ.

ADIPO'SA MEMBRA'NA. See CELLULOSA MEMBRANA.

ADIP'SIA, (from *α*, neg. and *διψα*, thirst.) WANT OF THIRST. Dr. Cullen ranks this as a genus of dis-

ease, in the *locales dysorexie*. But he thinks it is generally, if not always, symptomatic.

ADIP'SON, Αδιψον, (from *α*, neg. and *διψα*, thirst.) See OXYMEL and PTISANA.

Medicines were thus named that allayed thirst, if used for that purpose; and may be applied to such as do not provoke thirst.

The Greeks called liquorice-juice by this name. See GLYCYRRHIZA.

ADIP'SOS, (from *α*, priv. and *διψα*, thirst.) The EGYPTIAN PALM-TREE is thus named by the Greeks. Its fruit, before it is ripe, is called *myrobalans*. Theophrastus calls this tree βαλαν@, i. e. *mast*, from its fruit; but it is called *adipson*, because its fruit, before it is ripe, quenches thirst.

ADJUTO'RIMUM, (from *adjuvo*, to assist.) See HUMERUS, or upper part of the arm, clearly described by Albucasis. "Adjutorium is that bone which lies between the cubit and head of the scapula." It is also an external medicine used to assist internal ones.

ADLE, applied to an egg, means one not fecundated, or one putrid from long keeping: the former contains generally an unfarmed mola.

ADNA'TA, AGNA'TA, TUNICA, (from *adnascor*, to grow to.) The outer coat of the eye; called also *circumcualis*, *circumossalis*, *albuginea*, *epiophycos*. It is that which makes the WHITE OF THE EYE, called also *exclotion*, and is thus formed: five of the muscles which move the eye take their origin from the bottom of the orbit, and the sixth arises from the edge of it; they are all inserted by a tendinous expansion into the anterior part of the tunica sclerotica; and this expansion gives the whiteness peculiar to the fore part of the eye. It lies between the sclerotica and conjunctiva. It is extremely sensible, and abounds with blood-vessels, which are very visible in inflammations. It covers so much of the eye as is called the white; and, being reflected all round, it lines the two eye-lids, and thus hinders any thing from falling into the orbit. Where it covers the eye-lids, it is vascular and papillous. In passing over the orbit, it does not end at the cornea, but becomes transparent there, and is of different textures in different parts where it is spread. The sclerotica appears under it.

When a foreign body gets between the eye and the eye-lid, it is hooked in the villi: the best way to extricate it is, to invert the eye-lid, and to introduce a probe armed with lint and dipped in oil.

The inverted eye-lid proceeds from this coat. Though it is exactly commensurate to the orbit in health, yet, in morbid habits, when it is inflamed, it is thickened and puffed out. If it does not yield to general remedies, as bleeding, purging, &c. it must be punctured; and if this also fails, the redundant part must be cut off.

ADNA'TA, also signifies such parts of animal or vegetable bodies as are inseparable, as the hair, wool, fruits, horns; or else accidental, as fungus, misletoe, and excrescences.

ADONIS. *A. verna*, Lin. Sp. Pl. 771, and *A. Apennina*, L. 772. Plants whose roots are employed, according to Pallas, as emmenagogues. The practice of this country does not acknowledge their virtues, or record them.

ADOPTER. A chemical vessel with two necks in-

terposed between a retort and receiver. They differ from aludels in being long and open at each end; and in their position, which is usually oblique.

A'DOR, a sort of corn, (from *a*, neg. and *δορυ*, a spear,) so named from its being without the beard or spear; also called *spelta* and *zea*, SPELT CORN. Dioscorides mentions two kinds, the monococcous and dicoccous, that is, such as has only one grain or two in a husk.

A'DOS, (from *αδος*, satiety). Water in which red-hot iron is extinguished; because it is thereby quenched or satiated.

ADRAGA'NTH. See GUMMI TRAGACANTHIA.

ADRARHI'ZA, (from *αδρος*, thick, and *ρίζα*, a root.) See ARISTOLOCHIA.

ADROBO'LON, (from *αδρος*, large, and *βωλος*, a globe, hole, or mass). The Indian *bdellium*, which is coarser than the Arabian, being impure, black, and in large lumps.

ADRO'TERON, (from *αδρος*, plentiful). A prolific grain. See ALICA.

ADSCE'NDENS, (from *adscendo*, to ascend). Applied to a stalk, growing first in an horizontal direction, and then curving upwards. In anatomy, it refers to the direction of the vessels, as the ascending aorta.

ADSTRI'CTIO, (from *ad*, and *stringo*, to bind together,) ADSTRICTION. It either expresses the stypic quality of medicines, or the retention of the natural evacuations, by the rigidity of the respective apertures. It most commonly refers to the state of the bowels. See CONSTIPATIO.

ADSTRINGE'NTIA, (from *adstringo*, to bind up,) ASTRINGENTS. See ASTRINGENTIA.

ADU'NATOS, (from *a*, priv. and *δυναμις*, to be able.) See ADYNAMIA.

ADU'STA. ADUST, burnt, scorched, or parched, (from *aduro*, to burn, &c.). This term is applied to the fluids of the body when acrid, and particularly when the acrimony is supposed to have arisen from great heat. Those constitutions are bilious only, and the term is chiefly employed, when the bile from stagnation has become brown or black.

ADUSTION. See CAUTERY and MOXA. It is sometimes applied to violent inflammations of the brain, and cooling applications are used externally.

A'DY, vel PALMA A'DY, (from *αδυ*, or *ηδυ*, sweet). A palm-tree in the island of St. Thomas, which affords plenty of juice, that ferments into wine. The entire fruit is called by the Portuguese *caryoces* and *cariosse*; by the natives *abanga*. The fruit externally is like a lemon, and contains a stone, the kernel of which, if heated in hot water, gives out an oil of a saffron colour; it concretes in the cold, and is used as butter: of these kernels the inhabitants give three or four as a restorative, two or three times a day.

ADYNA'MIA, (from *a*, neg. and *δυναμις*, strength, force,) languor, weakness, impotence from sickness or disease: *adunatos*, *leipopsychia*. Also drowsiness, or sleepiness, lassitude, defect of vital powers. In Dr. Cullen's Nosology, this word distinguishes an order in his class *neuroses*: he defines it to be diseases consisting in a weakness or loss of motion, in either the vital or natural functions. These diseases are by others called *defectivi*.

ADY'NAMON, (from the same). A FACTITIOUS WINE. It is made of two parts of must and one of water, which are boiled together till as much is consumed as there was added of water.

ÆDO'IA, or AIDOIA, (from *αιδως*, modesty). See PUDENDA.

ÆDOSO'PHIA, (from *αιδως*, pudenda, and *ψοφω*, strepitum *edo*). In Sauvages, and Sagar, it is defined to be a flatus passing from the uterus, or from the urinary bladder, through the vagina or the urethra; hence it is formed into two species, ÆDOSOPHIA URE'THRE et UTERI'NA. This flatus is sometimes very fetid, which circumstance cannot always be accounted for. It sometimes happens when women are in labour, and hath been taken for a sign that the child is dead, but this cannot be depended on; an intolerable stench sometimes attends, when the child is living. See Sauvages' Nosologia Methodica, vol. ii. p. 417.

ÆGAGRO'PILA, (from *αιγαγρος*, the mountain-goat, and *πιλος*, *fila* vel *globulus*.) THE ROCK-GOAT. See CAPRA ALPINA.

ÆGEI'RINON, (*αιγειρον*, a poplar). An ointment so called, because the fruit of the poplar, or its catkins, are an ingredient in it; not now employed.

ÆGEI'ROS. See POPULUS.

Æ'GIAS, (from *αιξ*, a goat). A white speck on the pupil of the eye, which occasions a dimness of sight; so named, because it was supposed that goats were subject to it.

ÆGI'DES, *αιγιδης*, (from *αιξ*, a goat). Small white cicatrices of the eyes, or small white concretions on the pupil; called also *aglia*. They do not differ from the white specks called ALBUGO.

ÆGIDION, (from *αιξ*, a goat). The name of a collyrium, or ointment, for inflammations and defluxions of the eyes; so named because goats are supposed to be subject to defects in the eyes; called also *ægoprosophon*.

Æ'GILOPS. See ÆGYLOPS.

Æ'GLEUS. The appellation, in Galen, of the white chamæleon thistle, which was esculent; to distinguish it from the Erebennus, the black poisonous kind.

ÆGOPODIUM. GOAT-WEED. *A. podagrana*, Lin. It is sedative, and formerly applied to mitigate pains of gout, and to relieve piles, but not now employed. In its earlier state it is tender and esculent.

ÆGO'CERAS, (from *αιξ*, a goat, and *κερας*, a horn,) so called from its pods resembling the horns of a goat. See FENUM GRÆCUM.

ÆCO'LETHRON, from (*αιξ*, a goat, and *ολιθρος*, destruction,) a plant so named from its being thought poisonous to goats. Tournefort says it is the *chamærododendron*. See Mem. de l'Acad. Roy. des Sciences, 1704. *Azalea pontica*, Lin. Sp. Pl. 1669.

ÆGO'NYCHON, GROMWELL. So called from *αιξ*, a goat, and *ονυξ* a hoof, because of the hardness of the seed, resembling the hoof of a goat. See LITHOSPERMUM.

ÆGOPROSO'PHON, (from *αιξ*, a goat, and *προσωπον*, a face). See ÆGIDION.

Æ'GYLOPS or ÆGILOPS. A disease in the inward corner of the eye, (so called from *αιξ*, a goat, and *ωψ*, an eye, or goat's-eye,) because goats are supposed to be subject to this disease.

Paulus Ægineta calls it *anchylops* before it bursts, and *ægylops* after; but these are only different states of the fistula lachrymalis. Dr. Wallis thinks that the distinction should be preserved.—See his *Nosologia Methodica Oculorum*. Article, *Epiphora a Rhyade*.

Sometimes it is with, and at others without, inflammation. If it is attended with erosion, it terminates, though seldom, in a cancer. In opening this abscess, we should be careful not to cut the edge of the eye-lid, for an incurable wateriness will be occasioned.

When it is strumous, it proceeds from congestion, and the tubercle is round without discolouring the skin. If it is caused by inflammation, pain and redness appear over the eye. Sometimes it begins with a weeping, and is not suspected until a redness appears in the eye; and then, by a gentle pressure on the part, a matter is discharged, a part of which resembles the white of an egg. If this matter makes its way into the nose, it acquires a fetid smell.

As to the cure, if the case is recent, we should begin with a cautious use of bleeding and purging; or if these are contra-indicated, the alteratives most esteemed in scrofulous disorders should be used. The tumour may be resolved by anodyne and discutient applications; but if there is a tendency to a suppuration it should be hastened, and the discharge of the pus procured, with all convenient speed, lest the bone underneath should be affected: the abscess must be cleansed and healed, with the tinct. of myrrh and aloes mixed with mel rosæ. If the matter had passed also under the cilium, a powerful desiccative, such as strong lime-water, assisted by a compress, should be used.

If the periosteum under the tumour be laid bare, an exfoliation must be hastened by a caustic, and a passage opened into the nose, after which dry lint alone is sufficient. Too constricting medicines may produce a rhyas, see RHYAS: too digestive applications may give rise to an encanthis. See FISTULA LACHRYMALIS. See also Galen, Aetius, Celsus, Paulus Ægineta, Actuarius, Sennertus, Wiseman, Heister, Pott, Bell, Kirkland, Ware.

Æ'GYLOPS, or Æ'GILOPS. *Bromus Arvensis*, Lin. Sp. Pl. 113. The GREAT WILD OAT GRASS OR DRANK. It grows in hedges and the sides of fields in May. By culture it becomes a species of corn. In the northern parts of America it is improved to great advantage; and in the low wet boggy grounds in Great Britain it would be profitable, as it thrives best in water. It grows like oats, but in quality resembles rice. A decoction of the roots is said to kill worms.

ÆGYPTIA ANTIDOTUS, the EGYPTIAN ANTIDOTE. The name of several compositions.

———— MOSCHATA. See ABELMOSCHUS.

———— ULCERA, also called SYRIAN ULCERS. Aretæus describes an ulcer of the tonsils and fauces by these names; they are attended with a burning pain; the matter discharged from them infects the whole frame, and the patient is rendered miserable by its offensive smell.

ÆGYPTIA'CA. See PAPHYRUS.

ÆGYPTIA'CUM BALSAMUM. BALS. GILEAD. See BALSAMUM.

———— UNG., called also *mel Ægyptiacum*. It was attributed to Mesue, but its place is sup-

plied by the oxymel æruginis in the last London pharmacopœia: it is a detergent, and slightly caustic. Another kind, described by Hildanus, consists of mithridate, camphor, and treacle. Another kind, composed of lily roots and aromatics, was used as a cosmetic, and styled cinum. They resemble each other only in their colour, from which they are styled Ægyptiaca.

ÆGYPTIUM OLEUM. See CATAPUTIA; also the name of a topic used by the ancients in uterine disorders.

———— ALBUM. See CRINOMYRON.

———— CROCEUM UNG. Both these are described by Aetius.

———— PHARMACUM AD AU'RES. The name of one of Aetius's compositions.

ÆGYPTIUS PESSUS. A pessary described by Paulus Ægineta: it is made of honey, turpentine, saffron, oil, verdigris, &c.

ÆICHRYS'ON, (from *æi*, *always*, and *χρυσος*, *gold*; because the herb is always of a shining yellow). See SEDUM.

ÆIGLU'CES, (from *æi*, *always*, and *γλυκυσ*, *sweet*). A sweet sort of wine is thus named. When the fermentation has begun, the vessel is placed under water, and there kept all the winter, that it may be cool, and not be completely turned into wine.

ÆITHALIS, (from *æi*, *always*, and *θαλλω*, *to be green*). See SEDUM.

ÆIZOON, (from *æi*, *always*, and *ζωη*, *life*). See SEDUM.

Æ'EL. See ALLA.

ÆLU'ROPO, SYR. DE, (from *αιλουρος*, *a cat*, and *πους*, *feet*), so called from the resemblance of its leaves and flowers to a cat's foot. See GNAPHALIUM MONTANUM.

ÆMBI'LLÆ, (from *αιμξ*, *blood*; because the seeds are of a deep red colour). See LACCA.

ÆNE'A. An epithet given to the instrument called a catheter, from *brass*, the matter of which it was formerly made.

Æ'ON, *æon*, the whole age of a man. But Hippocrates uses it to signify the remains of a man's life. See also MEDULLA SPINALIS.

ÆO'NION, (from *αιωνιος*, *eternal*; because the sedum majus is an evergreen). See SEDUM.

ÆO'RA, (from *αιωρεω*, *to lift up*), to suspend on high. GESTATIO, a species of exercise used by the ancients, and of which Aetius gives the following account:

GESTATION, while it exercises the body and limbs, still they seem to be at rest. Of the motion there are several kinds.

1st, Swinging in a hammock, which, at the decline of a fever, is beneficial.

2dly, Being carried in a litter, in which the patient either sits or lies alone. It is useful when the gout, stone, and such other disorders attend, that do not admit of violent motions.

3dly, Riding in a chariot, which is of service in most chronical disorders, especially before the stronger exercise can be admitted.

4thly, Sailing in a boat or a ship. This produces various effects, according to the different agitation of the waters, and in many tedious chronical disorders proves efficacious beyond what is observed from the

most skilful administration of drugs. These are instances of passive exercise, and are useful, particularly when active exercise would be improper or impracticable. Asclepiades was the first who brought passive exercise into practice, which was used after severe illness, in order to conquer debility, and invigorate the system by gentle means.

The use of exercise in preserving or restoring health is too well known to require either arguments to enforce it, or regulations to conduct it. The exercises here enumerated, we have said, are passive only; and it is not easy to explain in what manner these can be useful. It may be remarked that all are attended with renovation of the air, which surrounds the body; all require some little exertion to preserve or restore the equilibrium. Dr. Cullen, taking the idea from the motion of a vessel containing a fluid, and observing that the momentum imparted to the latter continued when the motion of the former was suddenly stopped, supposed that the motion of the fluids in the blood vessels continued in the same way, stimulated the vessels, and thus promoted the circulation. The idea was ingenious; but, as the blood vessels are constantly full, we suspect that the analogy cannot be transferred; and the whole advantages of exercise must probably be attributed to the renovation of the surrounding air, and the exertion necessary to preserve the equilibrium. The kinds of exercise here mentioned, are progressive in these respects; and of course adapted to different states of debility. Swinging is a more active exercise; riding and walking progressively more so, and consequently adapted to the less delicate and infirm.

Other circumstances must, however, influence the choice of our modes of exercise. Sailing has been thought best adapted to hectic cases. The effluvia of the pitch, in the ship, may have some effect, but these could be obtained on shore; and, when this has been tried, no particular benefit has resulted. The sea air is certainly not peculiarly salutary in such cases; though, if the idea of Dr. Rush be admitted, that the mixture of sea and land air is rather injurious than useful, it will account for the disadvantages sometimes experienced from a residence near a harbour. The benefits, therefore, probably result from the exercise, which is constant; the general tendency of the circulation to the surface thus excited, assisted, perhaps, by the nausea. The tendency to the surface is evinced by the constipation of the bowels, and the rare occurrence of catarrhal affections on shipboard.

Riding on horseback has been equally commended in hectic cases by Sydenham, though not confirmed by more recent experience. This remedy is certainly better adapted to the more languid circulation, in the chylipoietic viscera; to obstructions of the liver; bad digestion; and want of appetite. The succussions which the viscera experience by the motion in the horse, must undoubtedly assist the circulation, when languid from indulgence and plethora, or when obstructed from indolence, or the immoderate use of wine and spirits.

Swinging, another remedy for phthisis, should have been mentioned after sailing. It has certainly been of service: the constant renewal of fresh cool air, for air constantly renewed in this climate must produce cold, checks a too high temperature, and lowers the pulse,

while the exercise determines the circulation to the surface.

For preserving health, however, *walking* is the best exercise: in all the other species, the extremities are not sufficiently warmed, while, by walking, the determination of the blood to the surface is general, every muscle has its share of exertion, and the viscera experience sufficient agitation to preserve their circulation undiminished in force, though perhaps not sufficient to restore it, if the organs are previously diseased.

A'ER, *Aer*, AIR, (from the Hebrew term *AOR*, *light*,) called also *gas ventosum*. From a variety of experiments, atmospheric air is proved to consist of a mixture of about seventy-two parts of azotic gas, to twenty-eight of oxygen, or vital air. Lavoisier says, of about twenty-seven parts of vital air, and seventy-three azotic. But the proportion of these two gases is subject to variation in the mixture which forms the atmosphere; depending upon local causes. From the decomposition of the atmospheric air, these two gases are obtained; and sometimes in their simple state, sometimes in a proportion different from what they hold when forming atmospheric air, are used for medicinal purposes. The oxygen, or vital air, may be considered as a stimulant, and invigorator of the system; whilst the azotic gas is a sedative, and hurtful to the constitution, by destroying its irritability. Before the present era of chemistry, it was the only gaseous substance known; and, indeed, almost all that has been formerly written on the air relates only to its physical properties. The chief of which are: First, That it is a fluid of extreme rarefaction, obedient to the smallest motion: the slightest agitation deranges its equilibrium, which is continually endeavouring to restore itself. Though very fluid, it passes through those orifices with difficulty, through which grosser fluids can pass with ease. Secondly, It is invisible; it refracts, but does not reflect the rays of light: it is inodorous, through the vehicle of odoriferous particles: it is insipid; and its physical qualities, chiefly, affect us variously. Thirdly, The weight of the *air* is not perceived but in large quantities; nor is the comparative weight easily, if at all, to be ascertained, as no two portions are ever of the same weight at different heights in the atmosphere. However, from long and repeated observations, the greatest gravity of the air in Europe is found to be equal, in equilibrio, with thirty inches and half of quicksilver in the barometer, and the least raises it only to twenty-seven and half. The weight of the common *air* about the surface of the earth, at the time of the middle weight of the atmosphere, and in every temperate season, is to that of water as one to 850. Fourthly, The elasticity of the air is one of the properties upon which natural philosophers have made the greatest number of experiments, and it has ever been applied with considerable advantage in the arts. Fifthly, *Air* is necessary to animal existence. This is evident from the experiments made with the air-pump; though not without some exceptions, for toads, vipers, eels, insects of all kinds, and fish, live for a time in the exhausted receiver. They cannot indeed live without oxygen, but they expend it slowly, and separate it more perfectly from the injurious part of the atmosphere. Sixthly, The particles of *air* are said to be too small for any microscope to discover,

and yet they are supposed to be larger than those of fire, water, oil, and many other fluids, since fire pervades glass; oil, water, &c. will pass through many compact substances, whilst air is resisted by strong paper. This argument is, however, fallacious. Seventhly, *Air* is a vehicle of sound, of the objects of taste, of effluvia to the nose, as is evident from observations made on the tops of high mountains, where our senses become duller than when we are nearer the plains. Eighthly, It is a part in the composition of all bodies. Ninthly, It cannot be rendered of itself solid by any known means. Tenthly, By contact and cohesion in the parts of bodies it becomes solid and unelastic; but when separated by heat, fermentation, &c. its elasticity returns. Heat rarifies, and cold condenses it.

The physical qualities of the air have occasioned numerous disquisitions. But extensive inquiries, the comparison of the tables of mortality, experience long continued, have allowed us to draw few conclusions which will bear the test of careful examination. In spring, we find inflammatory complaints; in autumn, bilious diseases: in every season, fevers, in the commencement inflammatory, in the conclusion more or less putrid. To be more particular. Continued cold produces that tension of the fibres, that strong and steady action, which we style inflammatory diathesis: high situations, with a pure bracing atmosphere, produce similar effects. These are partly owing to an excess of oxygen, as we shall presently notice; but, in a great measure, to moderate, continued cold. A previous moist, temperate winter, which predisposes to scrofulous complaints, will, at this period, produce the most fatal consequences in hectic cases. The fever will increase, the ulceration proceed with rapidity, and the heat of the ensuing summer close the scene. Those, however, who are moderately healthy and not peculiarly robust, will find a winter, of no extreme cold, healthy; and the opening spring, expanding the fibres, will give a genial glow and new life to every organ. Summer, of course, may produce its own diseases; but, if we peruse the history of epidemics, we shall, with difficulty, trace any particular bad effects of the heat, till the evenings begin to cool, the fruit to be plenty, and the bile to become a conspicuous cause of disease, from its accumulation and excessive discharges. Winter again recurs, and Dr. Heberden has endeavoured to shew, from the bills of mortality, that it is a fatal season. It may be so in general: old people resist cold with difficulty, and the catarrhus suffocativus, asthma, and similar complaints, are often fatal at this period. In our experience, however, it is not the cold, but the early warmth of spring succeeding cold, which is most injurious: the constitution, braced by cold, cannot bear the subsequent relaxation. A long damp summer has had similar effects.

Philosophers have taught us how much pressure we bear from the atmosphere; and of course, from the diminution of that pressure, we shall feel the want of tension or tone which results from the removal of any support. Thus, when the air is lighter we find a languor come on; when heavier, our spirits are more brisk and lively. The whole is not however owing to the absolute weight of the air, but, in part, to its elasticity; or rather our feelings of health and activity are in the compound ratio of both. Thus, at the height

of from 1200 to 2000 feet above the level of the sea, the pressure is greatly diminished; but we feel increased activity, as we are in general above the region of clouds, and the air is more elastic; and the languor felt in very high situations is not uniform or constant; so that it cannot depend on a constant cause. During rain, the mercury in the barometer is not depressed half an inch, yet we feel more languor than on the top of mountains, where it has probably fallen from five to ten inches.

In other respects the physical properties of the air seem to have little influence: the warmest and longest summers are often healthy: the coldest winters, with the exception of accidental inflammatory complaints, are the same: the warmest weather, with the dampest fogs, have been followed by no peculiar epidemic. It is what Hippocrates long since called the *το βειον*, something divine or inexplicable, that produces fevers and similar diseases; but, before we notice the "divinity that stirs within us," we must add a few remarks on situation, as connected with the physical properties of the air.

A dry elevated spot, on a gravelly soil, is said to be most wholesome, especially if sheltered from the east wind. Elevation is however relative; light clouds float in the atmosphere, about 1600 feet above the level of the sea; and the healthiest spot is said to be some way above this elevation. This appears, however, to be fanciful; and it has not been proved that atmospheric moisture alone is injurious. In dry gravelly elevated spots, experience has fixed the most salutary residence for consumptive cases; yet, in these, oxygen seems to abound, which is peculiarly injurious in such complaints; and air of a lower quality, as it has been styled, is seemingly as good; in the opinion of some, preferable. In asthmatic cases elevated spots are manifestly injurious. In fact, theorists may declaim, but facts give the lie to the most plausible declamations. A change is often necessary; and from the effects of that change, the conduct proper for each individual must be ascertained.

It is observed by some authors, that vaults, corn-magazines, apple-garrets, &c. should open to the north; for that point is invariably proper: but the south and west are constantly improper. The most healthy exposure, if a house is to be built, is said to be found by cutting one of the trees that grow there transversely with a saw, observing the rings: the side of the tree on which the distances between each ring are widest is the most healthy exposure, and the windows of the house, all other circumstances being the same, should ever face that way.

We have mentioned the effects of the east wind in general, and we shall now notice them more particularly, though it cannot be yet determined whether they belong to the chemical or physical properties of the air. The atmosphere, while the east winds prevail, is lurid; and, even when clear, the sun has not its brilliant hue. The strength is not equal to the usual exertions; the respiration is not free; the spirits not lively. Asthmatics and hypochondriacs feel it severely; yet it is often dry, and, when it rains during a south-east wind, its fall is frequently periodical, extending only to twelve or twenty-four hours; while the clouds constantly display a promise of fair weather: there is

seemingly a perpetual contest between the causes of rain and their antagonists, whatever they may be.

As we have now instruments by which the quality of the air may be measured, it might be presumed, that these would inform us of the cause of this singular state of the atmosphere. The east wind is not peculiar to any situation, so that it is not injurious from passing over a baleful desert, or a successive series of marshes; nor does the eudiometer show any particular ingredient which may impair health or induce disease. We have not mentioned this instrument in our disquisitions respecting air, as it chiefly informs us of its chemical qualities. As we now approach this subject, we may remark that, in all its forms, the assistance it affords is inconsiderable to the medical chemist. In crowded cities, and the most apparently healthy situations, remote from "the busy hum of men," its results are nearly the same. Chemists must decide whether this similarity in the appearances is owing to the imperfection of the instrument, or whether the injurious qualities of the air are not cognizable by it. We have now mentioned this instrument to excuse our future silence respecting it. Its forms, however, we shall afterwards describe, as future enquirers may be more successful. See EUDIOMETER.

We have said that air consists of oxygen and azote in a gaseous state. To this, when we speak more critically, we must add carbonic acid gas. It has been disputed, whether the principal ingredients are chemically combined, or only mixed mechanically. Neither is true. We cannot indeed mix oxygenous and azotic gas, so as to form a gaseous fluid like our atmosphere; yet they are not chemically united, so as to form a tertium quid; nor even in the more general sense of the word, so as to produce a substance partaking of their united properties; as, when we mix spirit with water, or dissolve sugar in any fluid, it seems that the particles are united in their nascent state, and adhere together rather than form a compound. It appears at first sight singular, that the oxygen which supports life should be in so small a proportion; but the singularity will soon vanish when we reflect, that oxygen alone would be as fatal in the lungs as arsenic in the stomach. It is, literally, like fire which warms; but in excess, will burn. This we chiefly mention to explain the inconveniencies arising in hectic and in asthmatic cases, from air too pure; in the latter it stimulates the weak lungs too violently; in the former it adds to the tone and the irritability of the vascular system, already too great. The mountaineer and farmer, who breathe air highly oxygenated, are strong, robust, and active, but scarcely ever fat. Oxygen makes no part of this animal fluid; and hydrogen and carbone, of which it chiefly consists, do not abound in these regions. Hydrogen, indeed, has been discovered by Saussure on the highest mountains; but its levity carries it beyond human habitations; it is an extraneous body, found in air, but not a component part of it. As its elasticity is inconsiderable, it certainly contributes to the languor experienced in highly elevated situations.

The aerial pathology has not yet been successfully cultivated. Man can live and enjoy health from the heat of twenty-eight to one hundred and eight degrees of Fahrenheit. He can exist in a constant fog, where the hygrometer proceeds beyond the extreme of hu-

midity; and, in air which supports the mercury only at twenty-two or twenty-three inches, he is robust and active. The sudden changes are indeed injurious; but the injuries are often transitory and inconsiderable; or, if severe, producing only temporary and acute diseases. But that our observations respecting the effects of the different airs may be more distinct, it is necessary to enlarge a little on the chemical properties of the different gases.

Besides the common, or atmospherical *air*, there are various other sorts, distinguished by their respective characteristics: 1st. *AIR, FIXED OR FIXABLE.* By Van Helmont, it was called *gas sylvestre*, from being produced in vast quantities from the burning of charcoal; from its apparent acid properties, *aërial acid, cretaceous acid, and carbonic acid*; and *fixed air*, as readily losing its elasticity, and fixing itself in many bodies. It is an invisible and permanently elastic fluid, superior in gravity to the common atmospheric air, and most other aërial fluids. It consists of twenty-eight parts of carbone, and seventy-two of oxygen, with some caloric, forming about one sixty-sixth of the common atmosphere, though, from its gravity, generally falling to the bottom. *It is unfit for respiration; easily dissolved in water; exceedingly destructive to animal life, and produced in great quantities naturally from combustible bodies and many chemical processes.* It is found at the bottom of pits; it rises from fermenting liquors; it is one and a half heavier than pure common *air*; water imbibes more than its own bulk of it; flame is extinguished, and animals are destroyed, by its influence: when the fixable *air* is separated from chalk and other calcareous substances, they become caustic, or, as they are now styled, pure: it is antiseptic, powerfully preventing and recovering from putrefaction, whence lime-kilns, which discharge great quantities of this *air*, would be useful in the neighbourhood of populous towns; in clysters it hath been very advantageously administered against putrid disorders, and, mixed with the drink, has been thought to conduce to the relief of patients labouring under putrid fevers. In the form of yeast it has also been administered with good effect in these disorders: but though it may be introduced into the stomach and intestines with advantage, if breathed into the lungs, it is mortal. To fixable *air* the chief property of some mineral waters is attributed: the Pyrmont and Seltzer water owe their brisk acidulous taste and sparkling appearance to it; and it dissolves iron in a small proportion, when it is mixed with water. Fixable *air* hath been found useful in cancerous, consumptive, scorbutic, and other disorders, where an antiseptic medicine might be expected to afford relief. It has not only been considered as antiputrescent, but also lithontriptic. When the stomach is disordered, carbonic acid air often gives a temporary and an useful stimulus. It is administered united with water by swallowing kali, or soda, in an effervescing state, or the one immediately after the other, that the effervescence may take place in the stomach.

*AIR, VITAL*; called also *dephlogisticated, empyreal air, and oxygenous gas*. From a variety of experiments, modern philosophers have proved, that in respiration a portion of *air* is lost; that the first effect produced, is the blood assuming a vermilion colour, by combining with pure air. The second is to establish a

real focus of heat in the lungs, maintained and kept up by the *air* of respiration. See HEAT, VITAL; and RESPIRATION.

**AIR, INFLAMMABLE.** It is the lightest of all the aëriform fluids: in general about twelve times lighter than atmospheric *air*. All animal and vegetable substances, which can be burned in the open *air*, charcoal excepted, will afford *inflammable air*, if heated in close vessels: though this is usually mixed with *air* of other kinds, with water, and with oleaginous matters. Charcoal, and several metals, afford *inflammable air* by heat, if water be present. Some metallic substances, during their solution in acids, afford, or extricate *inflammable air*, which is of the purest kind. The common process for obtaining it is by dissolving iron filings or shavings in diluted vitriolic acid. It occupies the upper parts of subterraneous caverns; and has been commonly found in mines and coal-pits, where it is called FIRE DAMP, because it is liable to take fire, and explode like gunpowder. When not combined with oxygen it extinguishes fire; kills animals as readily as fixable *air*; takes fire by the contact of the electric spark, provided vital *air* be present, or any combustible body already in a state of ignition, and burning with a brilliant flame. If about two parts, by measure, of *inflammable air*, and one of vital *air*, are mixed together, and set on fire in a vessel strongly closed, which may be done by the electric spark, the *air*, if pure, will almost totally disappear, and the product be water, and an acid. It holds about half its weight of water in solution, which imparts to it a disagreeable odour; is absorbed by vegetables, and becomes a component part of their oils and resins.

The SULPHUREOUS, the MURIATIC, and some other ACIDS assume the form of *AIR*: but as they are neither found in the atmosphere, nor applied to medical purposes, they form no part of the present subject.

**NITROUS AIR, or NITROGENOUS GAS, or AZOTIC GAS,** forms an object of considerable importance in chemistry and medicine. It is fatal, when alone, to animal life; though, in combination, highly advantageous to it. This gas, we have seen, forms a large proportion of atmospheric *air*; and the gaseous nitrous oxide produces effects in respiration highly animating and stimulant. It is also the distinguishing ingredient of animal substances; the principle of animalisation.

**NITROGEN GAS, or the mephitic air** of former authors, is very extensively diffused. Its specific gravity is inconsiderable, for it is lighter than atmospheric *air*, in the proportion of 985 to 1000. Nitrogen, with caloric, forms this gas; and, with different proportions of oxygen, the nitrous acid in its various forms. With the full proportion of oxygen, it forms the *nitric acid*, the aqua fortis of the shops: with a less proportion it becomes *nitrous acid*; with still less nitrous gas; and with a very small quantity the nitrous oxide. Nitrogenous gas is neither acid nor soluble in water; and the nitrous gas is employed as a test of the purity of *air* in the *eudiometer*, q. v. If the *air* contains oxygen, it thus changes the gas into nitrous acid; and a larger proportion of the acid is formed when the oxygen is more abundant; while with impure *air* no change is produced. In medicine it has scarcely been employed: it is said to be antiseptic, and to kill worms, but experience has neglected to register its effects, or has disregarded it.

The nitrous oxide is heavier than *air*, and soluble in double its quantity of water. The taste it imparts is sweet, and the odour agreeable, though slight. Combustible bodies, at a high temperature, decompose this oxide; and it unites with alkalis, though not with acids. In fact, if an acid, it is the lowest in the scale, and to dispute whether it be so, is to contend with *air*. Its effects on respiration are singular. It is said to animate the person who breathes it to a degree little inferior to phrensy: the sensations produced are highly pleasurable, and no languor follows. Though much must be allowed to the enthusiasm of a discoverer, and to the experience of effects wholly new and unexpected, yet very pleasing sensations have been undoubtedly felt on its being inhaled. To what these are owing has not been ascertained. A slight reflection will shew, that though life is really sustained by oxygen, yet this *air* is not proper for breathing for any continued period. The pleasure excited by fresh *air* does not arise from the oxygen, for it is not increased, or at least to an inconsiderable extent, in proportion to the quantity contained in the *air* breathed. Why azote, that is alone fatal to life, should be the necessary ingredient, is not clear. The great principle of distinction of animal substances, chemically considered, is indeed azote: this principle, so copious in these, is found in a small proportion, and only in particular parts, of the vegetable kingdom; and it is the great problem in the function of animalisation, to discover the sources of the azote. May it not then be the *air*, and may not the animal system feel a peculiar pleasure in the supply of this principle, which must neutralise, or assimilate, the vegetable food? It is not an improbable supposition, but it has escaped us, if it has been noticed by any former physiologist.

*Air*, in so many various ways injured, viz. by breathing, by burning bodies, &c. is restored by many means; a few of which only have been discovered. Plants absorb carbonic acid gas, and restore, in their turn, a pure *air*; and thus, combining with azote, may, imperceptibly to our senses, renovate the atmosphere. We may thus account for the different result of the experiments of philosophers, some of whom have discovered that plants exhale pure *air*, while others deny it. *Inflammable air* seeks the upper regions of the atmosphere, and is destroyed in the meteoric explosions, when too copious; while the portion arrested in its progress contributes, as we have said, to the production of the oils and resins of vegetables.

Thus nature very completely restores the various changes in the constitution of our atmosphere, which the different processes constantly going on may, in her regular course, have occasioned. Yet the *air* is accused as the cause of numerous diseases; and it really is so. Sudden cold checking the perspiration will apparently produce almost every form of the pyrexia. Partial cold will produce rheumatisms; damp *air*, catarrhs; and in old people those defluxions which are called humoral asthmas, and catarrhi suffocativi. The continued heat of summer occasions bilious disorders; and the cold of winter a return of the more active inflammations. The *air* is, however, chiefly a vehicle of injurious effluvia; some of which only can be ascertained. Marsh miasmata, as they are styled by pathologists, are the cause of numerous intermittent and remittent fevers, as well as those apparently of a more

continued form. It has been ascertained, that a clayey soil, when moistened, will attract the oxygen of the air, and leave its azotic part not sufficiently guarded to support the *vis vitæ*; and it is found that districts become unhealthy chiefly when the earth begins to appear, in consequence of a diminution of the water. It is singular, that Linnæus, with a view to prove the cause of intermittents to be an argillaceous earth, has traced very minutely the prevalence of intermittents in clayey countries; a circumstance which may be explained from the views just assigned. To this diminution of the oxygen must be added a larger and unusual proportion of inflammable air from the parts of marshes still covered by water. To these conjoined causes many epidemics are owing: and when the changes in the physical properties of the air appear to produce fevers, they act only as exciting causes of these miasmata, in a manner to be afterwards explained. See INFECTION and EPIDEMICS.

It is not found that an unusual proportion of fixed air is injurious: it falls to the lowest strata of the atmosphere; and, whatever be the quantity, it is apparently absorbed. The very extensive diffusion of catarrhs and other epidemics, of small pox, measles, &c. is from causes combined with the air, and no part of the atmosphere. The contagion of putrid fevers, viz. the contagion conveyed by the patient, or by the medium of the attendant's clothes, are substances combined with the air which the nicest instruments have not yet been able to detect, though much may be expected from the persevering ardour of modern experimental philosophers.

Hoffman, in his *Med. Rat. Syst. artic. De Aëre*, and Boerhaave on Air, have collected all that is valuable from their predecessors and contemporaries.

Hale's Statical Experiments. Chaptal's and Thomson's Chemistry. Huxham on Air and Epidemic Diseases. Shaw's Abridgment of Boyle's Works, in the article Air. Parkinson's Medical Pocket Book. Dobson on Fixed Air. Chaptal's Elements of Chemistry; also Lavoisier, Fourcroy, and Nicholson.

Æ'RA, (from *αιρω, tollo, to take away*). So called, because it is necessary to remove it. See LOLIUM.

AERATED WATER. See AQUÆ MINERALES and AQUÆ MINERALES ARTIFICIALES.

ÆRE'OLUM, a weight of about twenty grains.

AERIFICA'TIO, (from *aër, air*, and *fio, to become*). It is the producing of air from other bodies, or rather converting them into air.

ÆRIS FLOS, (from *ærs, copper*;) FLOWERS OF COPPER; *anthos, phrasium viride*, &c. Copper reduced to small grains, by pouring cold water on it when in a state of fusion. The cold water is poured on the copper as it runs out of the furnace into the receiver.

———— SQUAMÆ, FLAKES OF COPPER, fly off in hammering the metal when heated. The best are of a deep yellow colour, and rust if sprinkled with vinegar. These, from the Cyprian copper works, are called *helitis*.

———— vel VE'NERIS TINCTURA. R. *Ærug. æris* ʒ j. *aquæ ammon. et sp. vin.* R. *aa* ʒ ss. m. et stent simul, donec aqua colorem saphirinum acquisiverit. This tincture is an admirable preparation to make an injection for a gonorrhœa, if care be taken duly to dilute it,

and skill enough is possessed to know when the infection is only in the urethra: to an ounce of pure water, add one drop of the above tincture. Astringent injections are, however, especially in the early stages of the complaint, dangerous.

Dr. W. Saunders observes, in his Lectures on the Mat. Med. that all solutions of metals are sedative, or ease pain, provided that the solution is not too strong.

VENERIS VOLATILIS TINCTURA: R. *Limaturæ cupri.* ʒ j. *aquæ ammon.* ʒ xij. m. This solution hath been given internally to the quantity of four or five drops at a dose, as a diuretic. Boerhaave directs to be given three drops, in a morning fasting, with a glass of mead, and this dose to be daily doubled until the dose is twenty-four drops, to be continued for some days: thus he succeeded sometimes in curing dropsies, though in other instances it failed. When effectual, it produced very copious discharges of urine. This tincture is a good substitute for the *cuprum ammoniacum* of the Edinburgh Dispensatory.

Metallic astringents are more active than alum, more powerful, more easily and more quickly dissolved in the stomach; are more diffusive and extensive in their influence on the habit, and to be preferred when speedy effects are to be obtained. Of all the metals, copper is the most astringent, and most soluble in the stomach; but the dose is difficultly ascertained, because of the uncertainty of acid in the stomach, so that it is rarely used. Dr. Saunders observes, that an over dose of the *ærugo æris* is active, stimulant, and astringent, and so quickly proves emetic as to be thrown up before it hurts; that an under dose excites a nausea. This is of course most advantageous; but the tinc. *Veneris vol.* if given so as to purge and vomit, by its sudden action produces very good effects.

Dr. G. Fordyce advises us to avoid cupreous preparations, when the intention is to strengthen; but when it is designed to lessen irritability, he observes, they are extremely useful, particularly in hysteric cases attended with plethora, and in epileptic spasms. In several instances of intermittents, and of mortifications, the preparations of copper, such as were in a saline state, as the *cuprum ammoniacale*, the *cuprum vitriolatum*, and the tinct. *Veneris vol.* were equally efficacious with the bark; in this last case, the *cuprum vitriolatum* to gr. ss. for a dose has been very successful.

The copper, combined with the volatile alkali, either in the tinctures above described or in the *cuprum ammoniacale*, is undoubtedly an excellent remedy in epilepsies, and seems to act by lessening irritability. This is perhaps the principle by which also iron, zinc, and arsenic, produce their effect; but of these, iron seems to approach more nearly to what we with greater strictness call an *astringent*, q. v. Combined with zinc, the *zincum ustum*, or vitriol of zinc, the copper is often more effectual. Of intermittents, the copper and zinc are best adapted to the partial cases of the disease, as the *hemierania*, &c.; the arsenic to the more general forms.

Dr. Brown, in his Natural History of Jamaica, prefers preparations of copper in those dropsies which proceed from a general languor of the solid system, in which case they prove very useful as diuretics and strengtheners. He prefers the tinc. *Veneris vol.* to all

other preparations of this metal. In hot climates, where the body is much relaxed, the vitriol of copper is, he thinks, the best detergent of foul ulcers.

See Neumann's Chem. Works. Dict. of Chem. edit. ii.

ÆRI'TIS, (from *αἴρ*, the air,) so named from being of a sky-blue colour. See ANAGALLIS.

AEROLO'GIA, (from *αἴρ*, and *λογος*, *sermo*). That part of medicine which treats of air, explains its properties and use in the animal economy, and its efficacy in preserving and restoring health.

AEROME'LI, (from *αἴρ*, air, and *μελι*, honey), HONEY DEW. See MEL and MANNA.

AEROPHO'BI, (from *αἴρ*, air, and *φοβέω*, to be afraid). According to Cœlius Aurelianus, some phrenitic patients are afraid of a lucid and others of an obscure air, and these he calls *ærophobi*. So that,

AEROPHO'BIA, (from *αἴρ*, and *φοβία*, timor, fear,) is a symptom of the phrenitis. It is a fear of light, a kind of insanity, in which the patient dreads the air or light.

AERO'SIS, (from *αἴρ*, air). An imaginary resolution of the blood into vapour, supposed necessary to the support of the vital spirits, and to be brought about by the ventilation of the air during inspiration, in the manner that the flame of fuel is kindled by blowing it.

ÆROSUS LAPIS, (from *æs*, copper). So Pliny calls the cadmia, because of its sky colour, resembling the salts of copper, which is supposed to be Galen's *cadmia lapidosa*. See CADMIA.

ÆRUGINO'SUS, (from *ærugo*, verdigrise). Æruginous, of the colour of verdigrise, or green. This word is often applied to what is discharged by vomiting of this colour, and to the bile.

ÆRU'GO, (from *æs*, copper). The rust of any metal, but particularly of copper, called VERDIGRISE: it is also named *azagor*, *almizadir*. See ÆS.

The natural *ærugo* is a greenish marcasite, like the drops of iron; it is found in copper mines, but contains only a small proportion of the metal. HUNGARIAN MOUNTAIN OF SEA VERDIGRISE is found in the mountains of Moravia, in the form of sand.

— RA'SILIS. Hang a copper plate over the strongest vinegar, so as not to touch it, and after ten days scrape off the rust, which is thus called.

— SCOL'CIA. Of the two sorts, viz. the fossil and the factitious, the fossil is the best; but either is of no further use than the blue vitriol.

ÆRU'GO Æ'RIS; called also *viride æris*, *cupri rubigo*, *calcithos*, *Hispanicum viride*, VERDIGRISE. It is copper, corroded by a fermented vegetable acid into a bluish green substance. The copper is made into very thin plates, which are suspended over the vapours arising from wine, during its acetous fermentation: or the husks and stalks of grapes are dried, and, when bruised, are dipped in wine and made into balls. When they have acquired the acetous acid they are broken with the hand, and stratified with these copper plates, and left until the verdigrise is produced. The best, as well as the greatest quantity, is made at Montpellier, where there is one sort in powder and another in lumps. The whole process, as now practised in Montpellier, may be seen in the Cyclopaedia under VERDIGREASE. The sort which we receive from France is generally mixed with the stalks of grapes, which may be separated by

pulverisation, as they are more difficultly powdered than the verdigrise itself. It is purified by dissolving in six or seven times its weight of distilled vinegar, decanting and evaporating the solution. If good, it is dry, of a beautiful deep green, with a few white spots; and when rubbed on the hand with a little saliva or water it forms a smooth paste, free from grittiness. It is adulterated by mixing pumice stone, marble, vitriol, &c. The first two are discovered by rubbing the suspected verdigrise betwixt the thumb and the finger, previously wetted, by which the pumice stone and marble become white: the latter is discovered by burning a little on a tile, by which the vitriol is turned into a red substance. In spirit of wine, and in water, this concrete is partially soluble: in vinegar it is wholly so. If a saturated solution of it in vinegar is set to exhale in a warm place, the greatest part of the verdigrise may be recovered in a crystalline form; and if these crystals are distilled in a retort, the acetous acid ascends from them in a highly concentrated state, forming the acetic acid, and the crystals are then called distilled or calcined verdigrise, or the VITRIOL OF VENUS: if set in a damp place to dissolve, it is called the LIQUOR OF VENUS. Verdigrise is used by dyers, skimmers, hatters, painters, &c. as well as in medicine: in miniature painting the distilled sort is the best. Its use, as an external medicine, is to deterge foul ulcers, as in the ung. basil. viride and the mel æruginis. If it is made into a paste with saliva, or any thing not oily or unctuous, it will dissolve hard calli. In phagedenic ulcers, and the most unpromising sores, with ichor, fungus, &c. copper is useful. Foul chancres, that yield not to mercury inwardly, have been removed by a solution of the cuprum vitriolatum. Internally taken, a vomiting is instantly provoked by a grain or two of verdigrise, or vitriol of copper, so for its speedy effect it may be used to discharge any poisonous matter received into the stomach. Large portions, as four drams or more, have been swallowed without any other inconvenience than the present vomiting; yet, in smaller quantities, besides the vomiting, it excites a pain in the stomach and griping in the bowels, tenesmus, ulcerations, bloody stools, difficult breathing, and contractions of the limbs, which often terminate in death. Hence great care should be taken of copper or brass vessels, in which acids or fats are boiled, lest the verdigrise should be productive of disease. Though acids, &c. while boiling, do not corrode the metal, this is soon effected when the boiling heat is abated. In case of verdigrise being swallowed, oil and warm water, or large quantities of milk and water, both by the mouth and by the anus, in order to wash away the whole of this offensive matter, must be given; a discharge by vomiting with all possible speed must be excited; and, after due evacuations, an anodyne may be given: if there is great pain, cordials, with a milk diet, will be useful. Pills made of *ærugo*, we are informed by Gmelin, have been given as a remedy in cancers.

Verdigrise cannot be reduced to powder but by levigation.

ÆS, (from the Hebrew term *ÆS*, fire, *אש*, from *אש*, to burn,) called also *cuprum*, *χαλκος*, Venus, COPPER. It is found in many countries, but chiefly in Sweden, Hungary, and Germany.

The chemical character for copper is ♀.

Its gravity is to silver as eight to ten; to gold, as eight to nineteen; and to water, as eight to one: more strictly, it is from 7.780 to 8.584. A wire  $\frac{1}{10}$  of an inch will support about 300 weight.

It is considerably, but not entirely, fixed in the fire; changing first to a blue, then to a yellow, and then to a violet colour.

It is malleable, and ductile into a fine wire.

It is elastic and sonorous.

It melts not before ignition, or a strong white heat, but calcines by a weaker red heat into a red powder; and when in contact with the coals gives a greenish blue colour to the flame.

By heat, if the air has free access, it forms an imperfect blackish red oxide; with greater heat, a brown glass. When cooled slowly, it is said to crystallise in quadrilateral pyramids.

The sulphuret of copper is a very fusible mass: the phosphoret a grey and brilliant substance. It unites with the sulphuric acid when concentrated only with the assistance of heat, forming oblong rhomboidal crystals, which contain 0.32 of the metal, and 0.33 of acid.

Lime and magnesia precipitate the copper of a bluish white. Ammonia has a similar effect; but if in the slightest excess the precipitate is re-dissolved, forming the cuprum ammoniacum, the re-dissolved copper forms the aqua cœlestis of the pharmacæutists.

Copper is dissolved in diluted nitric acid, and forms crystals in long parallelograms or rhomboids. The muriatic acid only dissolves it when boiling and concentrated. The crystals are acid, of a green colour, and the precipitate is not very readily dissolved by ammonia. The green colour indicates, according to Guyton, a greater degree of oxygenation than the blue. The blue colour, we are told by Gren, when dissolved in ammoniac, does not take place unless air be admitted. Some authors have informed us, that fixed alkalis and neutral salts act on copper best also when exposed to the air and in the cold. Rancid fats and oils equally dissolve it.

Dissolved by fixed alkalis, it is green; by the volatile, it is blue. Dr. Lewis observes, that if the  $\frac{1}{100}$  part of a grain of copper be dissolved in a pint of water, a blue colour will be produced by adding a volatile alkali to it.

So great is its divisibility, that one grain dissolved in aqua ammoniæ will tincture 385,200 times its weight of water.

A small quantity of arsenic gives to copper a great degree of hardness and whiteness: thus pins may be made white and brittle by it. The hydrargyrus muriatus also whitens it; but pins are usually whitened with a solution of tin. If a piece of bright iron be immersed in the acid solution of copper, the acid quits the copper to attack the iron; and the copper, in its separation from the menstruum, adheres to the iron, which soon appears covered with a metallic cuprous coat. On these principles very minute quantities of copper dissolved in liquors may be readily discovered. The affinities of copper to other metals form no part of our subject at this time: we shall only add, that copper and tin make a good bell-metal, useful in microscopes and reflecting telescopes; copper and zinc, princes metal; copper with bronze and zinc, the white tonbac; with zinc,

by fusion, the similar or Manheim gold; or by cementation with lapis calaminaris, brass.

For an account of the different ores of copper, see Mineralogie de Hauy, vol. iii. 520, &c.

If copper is swallowed in its pure state, it is inoffensive. Some practitioners observe that copper, when dissolved, is strongly styptic; so far from causing exulceration of the intestines, that it heals them: it vomits by its nauseous stimulus, which will continue for several days.

ESECA'VUM, (the etymology of this word is uncertain,) BRASS, made by the union of copper, and calamine stone, which is owing merely to the zinc contained in the calamine: this is called *aurichalcum*, *azoth*. The alchemists found it out by attempting to turn copper into gold. Brass is not so readily dissolved as copper. The vapours of the zinc, which join with the copper in making brass, increase the weight of the copper sometimes to near one-half more than its original weight.

The following preparations are made from this metal: ÆS CORONA'RIMUM. See Æs.

ÆS USTUM, BURN'T COPPER. Thin plates of copper are laid stratum super stratum in a crucible, with sulphur and sea-salt; then they are placed over a hot charcoal fire, and there continued till all the sulphur is consumed, or until the plates can be reduced to a powder. If good, it is of an iron-grey on the outside, of a reddish grey within; and if two pieces are rubbed together, a vermilion red is produced: it must also be brittle and glittering when broken. It was formerly used for destroying fungous flesh, and drying up fistulous ulcers. With some aromatics, it has been given internally in epilepsies, and is recommended in diseases of the eyes.

If the burnt copper is made red-hot, and quenched in the oil nine times, then powdered, it takes the name of SAFFRON OF COPPER.

ÆSCHYNO'MENE (from *ασχυνωμι*, *I am ashamed*) SPINOSA; so called because it shrinks, as if ashamed, at the touch. See CAACO.

ÆSCULUS HIPPOCA'STANUM. See HIPPOCASTANUM.

ÆSTA'TES, (from *æstus*, *summer*,) FRECKLES in the face. See EPHELIDES.

ÆSTA'PHARA, (from *æstus*, *heat*, and *φερω*, *to bear*). See INCINERATIO.

ÆSTUA'RIMUM, (from *æstuo*, *to be hot*,) a vapour bath; sometimes STOVES or machines for conveying heat to rooms. See CALDARIUM.

ÆSTUA'TIO, (from *æstus*, *heat*). The boiling up, or rather the fermenting, of liquors when mixed.

ÆSTUS VOLA'TICUS, (from *æstus*, *heat*, and *volo*, *to fly*). Synonymous with *phlogosis*, according to Vogel. A sudden but transitory heat in the face.

ÆTAS, (from a Chaldean term, *ETTA*, *time*,—*ετος*, *age*,) ONE LIFE; an HUNDRED YEARS; also a CERTAIN STAGE OF LIFE. An age in history, or as relating to the life of man, is not, however, so extensive. It has usually been considered as the space of thirty years only; and Nestor, who is said to have lived three ages, has been only accounted ninety years old. The ancients reckoned six stages of life; viz. PUEERTIA, childhood, which is the fifth year of our age; ADOLESCENTIA, youth, reckoned to the eighteenth, and

properly so called to the twenty-fifth year; *JUVENTUS*, reckoned from the twenty-fifth to the thirty-fifth; *VIRILIS ÆTAS*, manhood, from the thirty-fifth to the fiftieth; *SENECTUS*, old age, from fifty to sixty; *DECREPITA ÆTAS*, decrepid age, which ends in death. Blanchard.

In a more strictly medical view, the ages are, however, differently divided; and the constitution changes according to a septenary period. At the age of seven, it seems to have attained its first stage. The form begins to appear; the character of the mind to be distinguishable. At fourteen, the period of puberty commences; and at twenty-one, such is the established state of mind and body, that the law rescues the man from pupillage. Little change occurs at twenty-eight; but at thirty-five the acmé of strength and intelligence is, by general consent, obtained. The two next periods include the stages of firm and robust health; and few begin to decline even at forty-nine. At fifty-six age begins to steal on, and the sixty-third year is supposed to be a period of peculiar danger. The threescore years and ten are consummated at the next period, and all beyond is declining health and vigour.

Every age hath its diseases; and Hippocrates observes, that those of youth, continuing after puberty, are difficult to cure. In infancy and old age, many object to the use of medicine; but, as in both these stages there is great infirmity, so there is a great scope both for the practice and the improvement of the medical art; neglect bespeaks an equal ignorance and inhumanity: some disorders may be radically cured, and all may be palliated. Infancy may be aided in its advances, and the infirmities of age may be retarded.

*ÆTHER*, in philosophy, is a subtle fluid, supposed by sir Issac Newton to fill all space, and to be the cause of gravitation and numerous other phenomena, inexplicable on other grounds. Sir Isaac, however, only suggested it as a probable cause of these phenomena, or in other words observed, that, if there were such a fluid with given properties, it *may* be the cause of the appearances mentioned. Such, however, was the character of this eminent philosopher, that his suppositions have been ranked with the demonstrations of other authors.

We shall only observe at present, that those who examine most minutely the operations of nature will be the least ready to reject this idea. A medium very different from the grosser ones which are subject to our senses appears necessary to explain the phenomena of sound, light, gravitation, electricity, Galvanism, &c. Let it have the properties assigned to it, or any other, some very subtle medium probably exists. That this æther is the nervous fluid, as some authors have contended, can neither be admitted nor denied. The whole, at present, is gratuitous. No facts have even proved its existence: it is the tortoise which, in our present views, must be put under the elephant; but we seem fast approaching to some further knowledge of these invisible fluids, and in the progress of this work may make some further steps in the enquiry.

See *NERVES*, and *NERVOUS FLUID*.

*ÆTHER*, vel *ETHER*, in chemistry, (from *αἶθερ*, *ardeo*, *splendeo*, *bright* and *splendid*,) is called *liquor æthereus vitriolicus*, *nitrosus*, *muraticus*, according to the acid from which it is formed, combined with al-

cohol. The idea of Macquer, who considered *æther* as a spirit of wine, dephlegmated, or deprived of water, has little foundation; for the distillation of spirit of wine from the driest alkali does not resemble *æther*.

Various are the processes by which *ÆTHER* is made. The following seems to be the best. Put a certain quantity of alcohol into a receiver, and very gradually add an equal quantity of concentrated sulphuric acid, shaking them together, and waiting till the first addition is incorporated before any more is put in; for, if they are poured together too rapidly, the succeeding heat and ebullition will dissipate a part of the mixture, break the vessel, and endanger the operator. After having mixed the whole in this gradual mode, the retort must be placed on a warm sand-bath, a receiver adapted, and the mixture heated to ebullition, keeping the retort cool with ice or the coldest water. Alcohol first passes over; soon after which, streams of fluid appear in the neck of the retort and within the receiver, which denote the rising of the æther. Its smell is agreeable: vapours of sulphureous acid succeed the æther; and the receiver must be taken away the moment they appear. If the distillation be continued, sulphureous æther is obtained; and the oil, which is called æthereal oil, or oil of wine, and that which remains in the retort, is a mixture of undecomposed acid, sulphur, and a matter resembling bitumen.

The chemical nature of æther is still little known. Fourcroy and Vauquelin think that in the process the alcohol is decomposed, and its ingredients form a new compound; but æther contains a larger proportion of hydrogen and oxygen, and a less proportion of carbone. Yet in various experiments with æther charcoal is deposited more copiously than from spirit of wine. Dabit, on the contrary, contends, that æther is only an oxygenated sulphurous acid. He has, however, failed in his proofs. Other chemists have, with greater reason, thought that the acid is decomposed, and that its oxygen unites with the hydrogen and carbone of the alcohol. Were this the place for chemical discussions, we could shew, that, though the latter opinion is nearer the truth than the former ones, yet that it is far from correct. When the æther is mixed with sulphureous vapours, it must be rectified by a gentle heat; some alkali being first added, to combine with the acid; or, what succeeds better, some black oxide of manganese.

This fluid, besides its appellation of *æther*, is by some named *acidum vitrioli vinosum*; by others, *spiritus æthereus*; and in the *Pharmacopœia Edinburgens.* it is entitled *spt. vini æthereus*; and as it may be obtained by means of the different acids, so from the acid employed an appropriate epithet has been added. It should be noted, that *æthers* produced by the different mineral acids possess different properties. The college of Physicians of London, in order to form the *LIQUOR ANODYNUS MINERALIS HOFFMANNI*, order *spiritus ætheris vitriolici* ℥ ij. et *oleum vini* ℥ iij. by weight. Chaptal says the composition is spirit of wine and æther, of each two ounces, and twelve drops of the æthereal oil. This is nearly also the composition of *TICKEL'S ETHER*. See *LIQUOR ANODYNUS HOFFMANNI*.

Various modes of preparing this fluid may be seen in the different writers, particularly London and Edinburgh *Pharmacopœias*.

Some of the properties of this liquid are as follow :

It is the most *light, volatile, and inflammable*, of all known liquids; with oxygenated fluids, it explodes. Its specific gravity is 0.758.

It swims on the highest rectified spirit of wine, as oil does upon water. In consequence of its volatility, it produces a high degree of cold in evaporating: boils at 98°; and in vacuo, at 20°; and freezes at 46°. It is one of the most powerful solvents known in chemistry. It will not mix with acids, alkalis, nor vinous spirits; but mixes with ten times its weight of water, by agitation; and is an effectual solvent of oils, balsams, resins, gum resins, wax, &c.

Equal parts of alcohol or æther with sulphuric acid, distilled or passed through ignited tubes of clay, produce what is called a carbonated, oily, hydrogenous gas. This, mixed with oxygenated muriatic gas, forms oil. It is from this property styled by the Dutch chemists, who discovered it, *olefant gas*. If the tube is of glass, carbone is deposited, and no such gas appears. If two parts of sea-salt, one of manganese, three of alcohol, and one of sulphuric acid, be distilled, a dulcified oxymuriatic acid first comes over, and then an oil called *oil of salt*.

It extracts gold, wherever it is, from any one or all of the baser metals; and thus gold is better and sooner purified than by any other means.

Æther is first described in the Dispensatory of Valerius Cordus, published in 1540: the public attention to it was, however, first excited by a publication in the Philosophical Transactions, A. D. 1730, by a German, who calls himself Frobenius. The late Dr. Ward was the first who is known to have used it in England; with æther he instantly relieved the headach, and other pains in the external parts; but for the first publication on its internal use, we are indebted to Mr. Turner, surgeon, in Liverpool, by whom it was prepared for a very extensive sale. He mixed two drams of æther with six or eight ounces of water, and gave from one to four large spoonfuls at a time, repeating the dose as required. Its general effects internally are anodyne and antispasmodic. Others give five or six drops for a dose, first dropping it on sugar; but five times the dose is not too great. In obstinate headachs, vertigos, convulsions, hysteria, rheumatism, flatulent and other disorders of the stomach and bowels, asthmas, hiccough, &c. by its application externally, or administration internally, or both, the most desirable effects have followed. When it is applied externally, procure a bit of linen rag, of such a dimension as to be conveniently covered with the palm of the hand: moisten the rag with the æther, and press it close to the part affected; in two or three minutes the rag will be found dry, and may be taken away: the application must be frequently repeated. Fred. Hoffman, indeed, employed it, in the form of his mineral liquor, as a sedative and antispasmodic.

The æther prepared by Mr. Tickel, of Bath, is recommended chiefly in hydrothorax, but none of the æthers are remarkably diuretic; and, from what we have seen, this medicine apparently acts only as an anodyne and an antispasmodic. In complaints where a remedy of this nature is required, Hoffman is extravagant in the praises of his mineral liquor; and, in later times, Mr. Clutton's febrifuge spirit is little more

than an æther acidulated, and disguised by some of the warmer vegetables.

Æther is either administered on sugar or mixed with water, by means of an almond or mucilage. It is however given with least loss in the former way, or dropped into any fluid in a vial, which must be immediately corked and inverted.

As to the tests of the goodness of æther, Mr. Turner informs us, "that the most perfect sort is obtained by the assistance of the vitriolic acid; that it is colourless, and strikes the nose very strongly with the sulphureous smell; a drop let fall on the hand instantly vanishes, without leaving any moisture behind; five or six drops dropped together upon a table will disappear in a few seconds, and leaves only the appearance of a large oily ring behind." The best æther requires the greatest quantity of water to be mixed with it; if, therefore, to six tea spoonfuls of water, in a small phial, you add one of the æther to be examined, cork it up, and shake them well together; and if, upon standing a little while, some of the æther appears at the top, in the form of oil, sufficient to cover the surface of the mixture, it is good, provided also that it answers the other methods of trial; but if none appears, or not enough to cover the face of the mixture, it was either adulterated or not well rectified: if to this mixture of æther and water you add a little salt of tartar, and any fermentation ensues, the æther was not well rectified. To obtain a powerful medicine, it is necessary that it be free from all adherence of the sulphureous acid, for in proportion to the acid, its virtues are greatly impaired.

See Malouin's *Chimie Medicinale*, tom. ii. p. 451. Dictionary of Chemistry, edit. ii. Dr. Frobenius's accounts of *Æther*, inserted in the Philosophical Transactions for 1733 and 1741. Pharm. Col. Edinb. The Lond. Med. Obs. and Inq. vol. ii. p. 176—186. An Account of the extraordinary Medicinal Fluid called *Æther*, by M. Turner, surgeon, in Liverpool. Abridgment of the Philosophical Transactions, vol. viii. p. 744. Cyclopedia, edit. A. D. 1788. Beaume's Dissertation on *Æther*. This last is the most complete work on this subject. Cullen's *Mat. Medica*. Chaptal, Lavoisier, Fourcroy, Thomson, *Annales de Chimie*, vols. 21, 23, 24, and 29, 34, 43. *Journal de Physique*, 45 and 46. Parkinson's *Chemical Pocket Book*.

ÆTHEREA HERBA. See ERYNGIUM.

ÆTHEREAL OIL, an animal or vegetable oil, highly rectified.

ÆTHIOPIS, (from *αἶψα*, to burn, and *ὤψ*, the face; so called because it is abundant in Æthiopia, and very hot climates,) ETHIOPIAN CLARY. *Salvia Æthiopis*. Linn. Its leaves are like those of mullein, hairy and thick; the stalk is quadrangular, like that of balm; the seeds are two in a cell. A decoction of its roots is commended in pleurisies and rheumatisms; but is an inert insignificant remedy. Raii Hist.

ÆTHIOPICÆ. This epithet is applied to many medicines from their black colour, like the skin of an Æthiopian.

PILUL. R. Merc. pur. cum mucilag. è gum. Arab. extinct. ʒ vi. sulph. ant. precip. res. guaiac. et mellis aa ʒ ss. f. mas. et divid. in pilul. No. ccxl. quarum detur i. ad iv. mane nocteque. These are in every respect equal to Dr. Plummer's in

point of usefulness, but not so apt to run off by a stool; see PLUMMERI PILULÆ.

**ÆTHIOPS ANTIMONIALIS**, ANTIMONIAL ÆTHIOPS. Dr. Cockburn, in his Treatise on the Gonorrhœa, directs us to melt equal parts of antimony and sea salt in a crucible, and separate the scorïæ, then to rub equal parts of the regulus made in this manner and mercury together, till they are incorporated. He extols it in cutaneous diseases, glandular obstructions, and many other chronical diseases: a few grains are given at first, and the quantity is increased as the patient can bear it. Malouin, in his Chemistry, gives various processes for uniting antimony with mercury, some of which are more speedy, and others more perfect in forming this combination; but all the preparations where the crude antimony is employed are inert, in consequence of the sulphur it contains. The Pillulæ Æthiopicae, taken from a former edition of the Edinburgh Dispensatory, are now omitted in the Pharmacopœia of both colleges.

**MARTIALIS**, MARTIAL ÆTHIOPS. Put filings of steel into an unglazed earthen vessel, with water enough to rise four inches above the filings; the whole is to be stirred every day, and more water supplied as that in the vessel exhales, so that the filings remain always covered; continue this process till they are reduced to a powder of an inky blackness. This medicine seems never to have attained the notice of physicians, though it may probably be an useful one. The iron is evidently oxygenated by the decomposition of the water, and it may be recollected, that in Griffith's medicine it experiences a similar change.

**MINERALIS**. Now called Hydrargyrus cum Sulphure, Lond. Ph. 1788. Æthiops, so called from its colour. ÆTHIOPS MINERAL is prepared by uniting equal parts of sulphur and mercury, with or without heat.

As sulphur so eminently abates the power of all the more active metals, this medicine is thought by many to be no further useful than as it is of efficacy in the stomach and bowels; others assert, that it enters the circulation, and is productive of very salutary effects. It is indeed possible; that a portion of the mercury may be separated from the sulphur, during the passage of the *æthiops* through the body. The dose is from gr. v. to ʒ ss. It is equally useful with the cinnab. antimonii for fumigating venereal ulcers: and, like the cinnabar, it is hard to say that it is useful in any other way. In the present form with a double proportion of mercury it may be more active.

**VEGETABILIS**. VEGETABLE ÆTHIOPS. By burning the sea-wrack in the open air, it is reduced into a black powder, and is then called *vegetable æthiops*. The soap-boilers call this kelp. The best is from Scotland. From ʒi. to ʒij. is given twice a day to remove scrofulous swellings.

**JOVIALIS**, is mentioned by Gmelin as useful in destroying tæniæ. It consists of equal parts of tin, mercury, and sulphur; but is probably a medicine of little value, as tin acts mechanically.

**ANTIPTHYSIUS**, ANTIRHEUMATICUS, DIURETICUS, and PURGANS, are denominated from their colour, and consist of mercury, with the Peruvian balsam; with gum guaiacum; with juniper gum; and with

manna or jalap. These combinations are wholly unknown in this country, and perhaps scarcely deserve to be known.

———— **A'LBUS**. See MERCURIUS ALKALIZATUS.

———— **MERCURII PER SE**, is a simple oxyde of mercury, prepared by trituration, with or without mucilage. It has been given in venereal affections, in inflammations of the liver, and intermittents; and seems to have been at one time a favourite with the German physicians.

**ETHO'LICES**, (from *αἶθεω*, to inflame or burn). Superficial pustules in the skin raised by heat.

**ETHU'SA ME'UM**. See MEUM.

**ETIOLO'GIA**, ETIOLOGY, (from *αἰτία*, a cause, *λογος*, a discourse on). A treatise on the causes of diseases, and their symptoms.

**Æ'TOIPHLE'BES**, EAGLE VEINS, (from *αετός*, an eagle, *φλέψ*, vein). According to Rufius Ephesius, the veins that pass through the temples to the head were thus called.

**ÆTO'LION**, (from *αετός*, an eagle, so called because the grain is the colour of eagle's feathers). See CNI-DIA GRANA.

**ÆTO'NYCHUM**, (from *αετός*, an eagle, and *ονύχ*, a claw or nail). The claw of an eagle. See LITHOSPER-MUM.

**AFFE'CTIO**, AN AFFECTION, (from *afficio*, to affect). This is expressed in Greek by *πᾶθος*, hence *pathema*, *passio*, and is synonymous with disease.

**AFFE'CTIO HYPOCHO'NDRIÆ**. See HYPO-CHONDRIACUS MORBUS.

**A'FFIDRA**, (from *αφιδραω*, to perspire). A name for ceruss, because it was thought to possess the power of promoting perspiration. See CERUSSA, N° 1, under PLUMBUM.

**AFFI'NITAS**, AFFINITY, (from *affinis*, connected). *Attractio*, CHEMICAL AFFINITY, also called ELECTIVE ATTRACTION, may be defined the superior attraction evinced by all bodies for some particular substance; an attraction so great, that the component parts of a body are separated to enable the ingredients to form a new union.

Attraction is of different kinds in nature, though probably they all depend ultimately on the same principles: they are, 1. The attraction of gravitation. 2. The magnetic attraction. 3. The attraction of electricity. 4. The attraction of cohesion or of aggregation. 5. Chemical attraction, which is that tendency which bodies have, however different, to unite together, and to remain in union: e. gr. an acid unites with a metal, an earth, or an alkaline salt, and with either of these the acid forms one body; which body does not consist of a combination of the properties of the acid and the metal, &c.; but these losing their original properties on their union, a new body, different from either, is formed. 6. Elective attraction, or affinity, as already explained.

Chemical attraction does not usually take place but when the respective bodies, or one of them, are in a fluid state. Before chemical attraction can take place betwixt two or more bodies, it is necessary to destroy their attraction of aggregation or cohesion; this is effected by dissolving them. The component parts of bodies cannot come into the necessary contact with each

other until the integrant parts of the bodies, which are to act and be acted on, are separated by a solution of them. Dry bodies, however finely powdered, sometimes unite chemically; and sometimes elective attractions take place when both the bodies are in a dry powder. Attraction of aggregation requires only the application of surfaces; but chemical attraction usually requires fluidity.

The power in bodies on which their various transpositions and combinations depend, and which is called their *affinity*, is a term like the Newtonian attraction, designed to express not the cause but the effect. When an acid spontaneously quits a metal to unite with an alkali, it is said that it hath a greater *affinity* to the alkali than to the metal; this is only to say, in other words, that it will unite with the alkali in preference to the metal.

The doctrine of the *affinities* of bodies is of very extensive use in chemical pharmacy; for as several processes are founded on it, so if an error happens, and the medicine proves unfit for its intended use, it may be rendered applicable to other purposes, by such transpositions of their component parts as are pointed out by the knowledge of their *affinities*. Combinations and separations that are chemical depend on elective attraction.

Tables of elective attraction include every chemical fact of importance; as the whole science consists only of the union of bodies, and the separation of the component parts of such as are not simple. The whole doctrine would however be misplaced in a work of this kind; yet, as the subject is so closely connected with chemical pharmacy, we must add the outlines. Chemical affinity or attraction was first spoken of by Barchusen, from whom Boerhaave adopted this or similar language. Geoffroy however first collected all the known facts of this kind in the form of a table, in the year 1718. The term elective attraction—perhaps not strictly proper, as implying a *choice*, yet not ill applied, as chemical attractions are not indiscriminate—was, we believe, first introduced by Dr. Cullen, who made some important advances in giving chemistry a scientific form. He was followed by Dr. Black, and afterwards by Bergman. Yet Geoffroy's table was published, with improvements by Grosse, in 1730; Gellert, in 1750; Andiger, in 1756; Marchen, in 1762; De Fouchy, in 1773; Machy, Erxleben, Viegel, and Bergman, in 1775. Rouelle's, Limbourg's, and Sage's tables appeared between 1760 and 1775; but the dates we cannot now ascertain. Bergman's tables are usually preferred, though that annexed to the translation of Gren's chemistry we think superior. We shall however give that of Bergman, omitting the affinities of platina, and with some of the modern improvements; as that of Gren is so minutely exact, as to confuse, in some degree, the less experienced chemist; and unnecessarily so for our present purpose. Those who would engage in this subject at greater length will find excellent assistance in the new French Encyclopedia, or in the Annales de Chimie, vols. 36, 37, 38 and 39, where M. Berthollet has given some excellent papers on the laws of affinity. M. Morveau has also published *Principes Theoriques et Pratiques des Affinités ou Attractions Chimiques*.

The papers have been translated in some of the

earlier volumes of the Philosophical Magazine, and the later work on this subject has been lately translated in two volumes 8vo. We may just add, that the symbolical characters of chemical substances, used in the earlier tables, are now generally disused, as they are so numerous as to be with difficulty learnt or recollected.

It is no part of our present object to follow minutely the disquisitions of Morveau. It is sufficient for our purpose to point out, by the tables, the comparative force of attraction of a given substance for the various other chemical bodies. It has however been a desideratum to ascertain the precise numerical degree of attraction of these different bodies; and Mr. Kirwan has laboured with great success in this field. We need only refer to his labours in the Philosophical Transactions for 1780 and 1781, as well as the fourth and subsequent volumes of the Irish Transactions. M. M. Wenzel, Achard, Morveau, and Berthollet, preceded him with unequal success.

To understand the following table, it is only necessary to remark, that the substance at the top in capital letters has the greatest affinity with that immediately under it, and a less, in succession, with those which follow. Of consequence, the substance most remote from the uppermost will be separated from an union with it by one nearer it in the series. Where the spaces are different it shews an unusual difference in the powers.

Nitric Acids

The affinities of oxygen, as ascertained by later observations, appear to be nearly in this order:—

OXYGEN—Charcoal, titanium, manganese, zinc, iron, tin, uranium, molybdenum, tungstein, cobalt, antimony, hydrogen, phosphorus, sulphur, nickel, arsenic, nitrogen, chrome, bismuth, lead, copper, tellurium, platina, mercury, silver, nitrous gas, gold, muriatic acid.

## TABLES OF DOUBLE ELECTIVE AFFINITIES, OR ATTRACTIONS.

## I. WHAT OCCURS IN MIXTURES BY FUSION.

1. { Tin, mixed with Silver, with	Join with	{ Iron, mixed with Lead.
2. { Copper, with Gold,	Join with	{ Sulphur, with Lead.
3. { M. S. Gold,	Join with	{ Sulphur, with Regulus of antimony.

## II. WHAT OCCURS IN MIXTURES OF WATERY SUBSTANCES.

1. { Acids, mixed with Calcareous earths, or Metallic substances,	Join with	{ Volatile alkali, mixed with Fixed air.
2. { Vitriolic or marine acid, with Alkalis or earths,	Join with	{ Mercury, silver, or Lead, with Nitrous, or acetous acid.
3. { Lead, Nitrous, marine, or Acetous acid, Silver.	Join with	{ Vitriolic acids, Alkalis, earths, or M. S.
4. { Vitriolic, nitrous, or Acetous acid,	Join with	{ Marine acids, Alkaline salts, earths, or M. S.
5. { Volatile alkali, Acids,	Join with	{ Fixed air, and Fixed alkali.
6. { Nitrous, marine, and Acetous acids, Calcareous earths,	Join with	{ Volatile alkali, magnesia, earth of alum, Vitriolic acid.

From this may be experienced the nature of Double Elective Attraction when it takes place. Suppose the volatile alkali combined with any of the acids, the fixed air with fixed alkali; these substances separately combined (No. 5.) will decompose each other; for the volatile alkali will unite with the fixed air, and the acid with the fixed alkali.

## III. WHAT OCCURS IN DISTILLATION, OR SUBLIMATIONS, AND RESIDUES HEAT.

1. { Volatile alkali, mixed with Acids.	Join with	{ Fixed air, mixed with Calcareous earths.
2. { Volatile alkali, with Vitriolic acid, Volatile alkali, Nitrous, marine, or Vitriolic acids, Regulus of antimony,	Join with	{ Nitrous, marine, or acetous acid, with Fixed alkali. Acetous acid, Fixed alkali, or Absorbent earths.
4. { Sulphur,	Join with	{ Marine acid, Quicksilver.

See Dictionary of Chemistry, translated from the French; Black's Lectures; Chaptal, Fourcroy, and Thomson's Chemistry; Morveau's Papers in the Annales de Chimie; Kirwan; Phil. and Irish Trans.; besides those above quoted, may be consulted on this subject.

AFFINITY, COMPOUND, implies the union of different bodies in one homogeneous mass. Thus, alum, vitriolated tartar, a small proportion of alcohol and water, form a transparent fluid.

COMPOUND, ELECTIVE, we thus distinguish what is called double elective attraction, since, in many cases, there are more than four substances. If, for instance, nitric acid be added to the sulphat of ammonia, no decomposition takes place; but let nitrat of potash be added, and two new bodies are formed; that is, the potash attracts the sulphuric acid, while the nitric acid solicits the ammonia. This was familiarly explained by Dr. Black in the following manner:

Suppose the two lines, two rulers, moving freely on the centre, if the affinity between the potash and sulphuric acid be equal to 62, that between nitric acid and ammonia equal to 38, the sum of these affinities will be superior to the affinities supposed to keep the sulphuric acid and ammonia—the potash and nitric acid together, in the proportion of their sums, viz. 100 to 96. Bergman and Elliott have given different diagrams, which we need not copy. Berthollet has shewn that these representations are not chemically exact; but this would lead us into the intricacies of another science.

INTERMEDIATE, means the union of bodies by an intermede. The usual instance of water uniting with oil by the medium of mucilage, is incorrect; for this is not an union, but an intimate mixture of particles unaltered. Azote will not unite with fixed

alkalis, but when combined with other bodies in the form of nitric acid, the union is ready and permanent.

**AFFINITY, QUIESCENT and DWELLEN.** These terms are employed by Mr. Kirwan; the former to express the force exerted to preserve the old combination; the latter that which tends to destroy it. In the former example, the quiescent affinity between the ingredients of the sulphat of ammonia and the nitrat of potash, respectively, was equal only to 96; that of the other two bodies, respectively, equal to 100.

———— **RECIPROCAL**, forms a singular phenomenon in chemisiry. A body consisting of two principles may be separated by another, which, with one of the principles of the first, forms a new compound; but the separated principle, after some time, will effect a separation of the new union.

**A'FFION**, (ASSUN,) an Arabian name of opium; also of an electuary, in which opium is a part of the composition. See OPIUM.

**AFFLA'TUS**, or **ADFLA'TUS**, (from *ad*, and *flo*, to blow). When a vapour or air strikes any other body with a certain degree of violence, or, as the country-people call it, a BLAST, it affects the body suddenly with a disease; it is a species of erysipelas.

**AFFLI'CTIO**, (from *affligo*, to afflict). See PASSIONS.

**AFFO'DILUS**. See ASPHODELUS LUTEUS.

**AFFRODI'NA**, or **AFFRODI'TE**, (from *αφρος*, foam,) so named because Venus is said to have sprung from the foam of the sea. See VENUS.

**AFFU'SIO**, (from *ad* and *fundo*, to pour on). Pouring a liquor upon something; it means occasionally the same as *suffusio*. See CATARACTA.

**AFTO**. A kind of erysimum, or hedge mustard, from the coast of Guinea. When powdered it is used as snuff by the Africans to cure the head-ach.

**AGALA'CTIA**, (from *α*, negative, and *γαλα*, milk,) a defect of milk in child-bed; hence *αγαλακτις*, an epithet given by Hippocrates to a lying-in woman that hath no milk.

**AGA'LLOCHUM**, an Arabian term. **AGALLUGEN**—*αγαλλοχον*, *lignum Indicum*—*aloe aromatica*. The AROMATIC ALOE. The accounts given of this wood are so different from each other, as well as from the specimens of it that are met with in our shops, that the real wood is probably unknown. Other woods, as the *asphaltum*, *aquile lignum*, and *calambour*, which are said to be of the same nature, are substituted for it. Whatever this article is in reality, it is also expressed by different writers by the following names, viz. *aloe lign*, *xyloaloe*, *sinkoo*, *calambac*, *alud*, *haud*, *agalugi*, *heud*, &c. The Arabians call it *ceber*, or *sebar*, and sometimes *alcebar*. The Portuguese, *Pao-agula*.

There are two species of plants which afford a wood which is thus entitled. The *A. verum*, which is the *exœcaria agallocha* Lin. Sp. Pl. 1451, and the *aloexylum verum* of Loureiro. This also has been styled *A. verum*. See Transactions of the Lisbon Academy, vol. i.

It is brought from China, and the interior parts of the East Indies, in small pieces. It is described as being compact, ponderous, of a yellow or rusty brown colour, with black or purplish veins, sometimes purple, with ash-coloured veins, and not unfrequently as being of a blackish colour. Such as is brought into Europe

has a bitterish, resinous taste, and a light aromatic smell. Set on fire, it seems to melt like wax, emitting, while it burns, an agreeable fragrance; the degree of this fragrance gives the proof of its goodness. That part which is betwixt the heart, and that part which is next the bark, are called *calumbac*.

One ounce of this wood yields to spirits of wine three drams of a resinous extract; and to water two drams. If distilled with water, it yields an highly cordial oil, in the proportion of half an ounce from one hundred and sixty ounces. Miller. Dale.

Later authors, who professedly speak of the *aloexylum*, a word expressing the wood of aloes, describe it as a milky wood, very poisonous; adding, that the pith is intensely bitter. It is said to be highly acrid and inebriating, fatal to worms, and useful in palsy; or, in a smaller dose, in cholera. The common dose is a scruple. A resin and an essential oil are prepared from it. Sonnerat has lately sent to Lanarck a branch of the true wood, accompanied with a drawing of the flower, which shews that it is not of the genus above mentioned, though figured by Rumphius under the appellation of *A. secundarium*. Yet a plant of Amboyna may yield a similar resin with one of Cochinchina. Loureiro is, however, confident that the *agallochum* sold in India comes from the *aloexylum verum*. Another kind of wood under this name comes from Mexico, and is distinguished by its agreeable smell. The species is not known.

**AGA'LLUGI**, **AGAL'LUGEN**. See AGA'LLOCHUM.

**AGARICOIDES**, (from *αγαρικον*, and *ειδος*, form,) a sort of fungus, like agaric.

**AGA'RICUS AURI'CLÆ FO'RMA**. See AURICULÆ JUDÆ.

**AGA'RICUS**, **AGARIC**, supposed from Agaria, a town in Asia. Many species of fungi have this term, all of which are acrid and poisonous.

———— **MUSCARI'US**, Lin. Sp. Pl. 1645. The REDDISH MUSHROOMS, also called BUG AGARIC. This is one of the poisonous vegetables that are indigenous in Great Britain. The pillar stalk is white, thick, and hollow; thicker towards the top; egg-shaped at its base; surrounded at its middle with a pendulous membrane, and furnished with a cap which is sometimes six inches or more in diameter; almost flat; either white, red, or crimson colour; and sometimes beset with angular, downy, white, or red warts. The gills are white, flat, and inversely spear-shaped; the greater number extend from the rim of the cap to the stalk, the rest only half way. When this mushroom is decaying, the gills become brownish. It is found in pastures and woods.

If the juice of this mushroom is rubbed where bugs retreat in the day, it will destroy them. If infused in milk, it is destructive to flies the instant they sip it. Haller relates, that six persons of Lithuania perished at one time by eating this kind of mushroom; and that others have been driven mad by it. Two or three may be taken without danger; but more will occasion delirium. See Withering's Botanical Arrangements. Wilmer's Observations on Poisonous Vegetables. Lightfoot's Flora Scotia, vol. ii. p. 1010.

Yet, like all the agarics, it has the character of being cathartic and sudorific. In fact, nature exerts herself to

throw off the poisonous matter, and thus occasions these discharges. It has, however, been given internally in cases of epilepsy and palsy from a repulsion of eruptions. The dose is from ten to thirty grains in vinegar, the usual antidote to poisonous vegetables. If any one should be found so rash to employ it, we may add that the part only just above the ground is to be selected. This is cleaned, dried, powdered, and kept in a well-closed vial. It entered as an ingredient in the well known formula of the theriaca, when it was considered as a cordial.

**AGARICUS PIPERA'TUS**, Lin. 1741. **PEPPER MUSHROOM**; also called **PEPPER AGARIC**. The stalk is about two inches high. The hat is convex when young: as it expands, it becomes nearly flat; its colour is a dirty white, with a mixture of grey; it contains a milky juice. The disk is constantly bent inwards: when the fungus is decaying, the hat becomes in its centre, and is sometimes seen funnel-shaped. The lamellæ are close, numerous, and of a pale flesh colour.

It is very common in woods, near the roots of trees. When freely taken, fatal consequences are said by several writers to have resulted. When this vegetable has lost its acrid juice by drying, its caustic quality still remains. In distillation it gives out ammonia.

In case of injury from any of the mushroom tribe, see **AMANTIA**. See also Wilmer's Observations on Poisonous Vegetables.

**QUE'RCUS**, **AGARIC** of the oak, called *fungus igniarius*. *Boletus igniarius*, Lin. 1645. **FEMALE AGARIC**, and, from its readiness to catch fire, **TOUCH-WOOD**.

It grows in the form of a horse's hoof; externally it is of a dusky ash-colour, and internally of a dusky red; it is soft and tough. The best is said to grow on the larger branches of oak trees; but that which is found on other trees is often as good.

It consists of four parts, which present themselves successively. 1st. The outward rind, which may be thrown away. 2d. The part immediately under this rind, which is the best of all, and is used to restrain hæmorrhages from wounds, and after amputations; it should be beat well with a hammer until it is soft and pliable, then slices of it of a proper size are to be applied upon the open blood vessel, whose discharge it restrains, not from its restringency, but its texture and adhesive quality: on the first application it adheres pretty strongly, but about the end of two days it begins to separate and soon falls off. 3d. A part which adheres to the second, and which is an inferior sort, may be used in less important cases. The 4th, or last part, may be powdered, and then used for the same purposes as the second and third sorts. The best time for taking the fungous substance from the trees is autumn, when the weather is fine, and after great heats.

As a styptic, this fungus does not appear to possess any advantages greater than what may be expected from dry lint, as its success hath not been manifested but when the circulation was so languid that lint would not have failed to have answered as well. This *agaric* grows on different trees, chiefly on the ash.

See Warner's Cases in Surgery, p. 133, &c. Neale's Observations on the Use of *Agaric*.

**MINERALIS**, called *lac lunæ*, *lac montium*,

and *medulla lapidum*. It is collected in the clefts of the secondary mountains, and, when dry and powdered, is styled *fossil farina*. It has been employed in some instances as a desiccative; but is little known to the practitioners of this country. It is often mixed with clay, and is sometimes a pure clay. The *santa flora*, however, of Sienna, of which bricks that swim in water are formed, contains a much larger proportion of flint and magnesia than of clay.

**AGA'SYLIS**, (from *αγαμαι*, to be wonderful). Dioscorides says, that this is the tree from whence the ammoniacum is produced, so named from its surprising good properties. See **AMMONIACUM**.

**AGATHO'NIS ANTIDO'TUS HEPATICA**. Agathon's antidote for the liver.

β. Gentian. 3 vi. R. Enul. C. Fol. Abs. et Fol. Nard. Ind. añ 3 i. m.

**AGENE'SIA**, (α, non, and *γενεσις*, generatio). See **ANAPHRODISIA**, and **DYSPERMATISMUS**.

**AGER NATU'RÆ**. See **UTERUS**.

**AGE'RATUM**, (α, non, and *γρηγας*, senectus,) because its flowers preserve their beauty a long time. It is also named *balsamita minor*; *costus hortorum minor*; **SWEET MAUDLIN**, or **MAUDLIN TANSEY**. It is the **ACHILLEA AGERATUM** of Linnæus. Sp. Pl. 1264.

The other species of achillea are the *A. litrata* Lin. 1267, the true genepi of the shops; the *A. millefolium* Lin. 1267; *A. moschata* (odorata, Lin. 1268); *A. ptarmica*, Lin. 1266. These agree in a pleasing smell, and a bitterish taste, resembling the costmary and tansey. Their virtues, though inconsiderable, are best extracted by water. To this, however, the ptarmica is an exception; for the smell of the flowers is nauseous; the taste of the root acrid and pungent. The former species are used in stomach complaints; the last as an errhine and a sialagogue, to relieve the tooth-ach, and as a remedy for palsy.

**AGERATUS LAPIS**, (*ageratus*, common). A stone used by cobblers to polish women's shoes. It is ridiculously said to discuss, and to be gently astringent. If it possesses any such virtues, it probably contains iron, a supposition countenanced by its being used in dyeing.

**AGE'VITA**. The name of an antidote, rather supposed to be called *jugis vita*, long, or continual life. It is a medicated wine, made with galangal root, long and white pepper, sage, ginger, cinnamon, saffron, and cloves, boiled in wine.

**AGGLOMERA'TIO**, (from *ad* and *glomero*, to roll together). The rolling or mixing together two or more substances into one mass.

**AGGLUTINA'TIO**, (from *ad* and *glutino*, to solder together,) **AGGLUTINATION**. Reunion, sticking together: so healers are agglutinants.

**PILORUM**. Reducing the hair of the eye-lids that grow inward, to their natural order, by any glutinous matter on a probe.

**AGGLUTINANTS**. A class of medicines which united wounds, were supposed to have this effect. They consisted of substances which contained gluten, and were thought capable of supplying that portion of the blood whose effects on wounds were sufficiently obvious. They are now known to be useless. If any such internal medicine exists, it is gum arabic, in a very large dose taken daily for a considerable time.

The other agglutinants are merely nutritious, except the olibanum, which acts in humoral asthmas on a different principle.

**AGGREGATÆ GLANDULÆ**, (from *aggrego*, to assemble together). Small glands, supposed to be lodged in the cellular coat of the intestines next to the villous; but as they do not appear in an uninjected gut, many anatomists suspect them only to be little bits of separated wax.

**AGGREGA'TUM**, (from the same,) an **AGGREGATE**. A body resulting from the union of many others which are smaller, of which the whole sum is the aggregate.

**AGGREGA'TUS**, (from the same). In botany it is an epithet applied to those parts of plants, which are so united that they cannot be separated without injury to the economy of the whole.

**AGHEUS'TIA**, } ( $\alpha$ , non, and  $\gamma\epsilon\nu\omicron\mu\alpha\iota$ , *gusto*). **DE-AGEUS'TIA**, } **FECT**, or **LOSS OF TASTE**, called also *Apogeusia*, *Apogecusis*. Dr. Cullen ranks this as a genus of disease, in the class *locales*, and order *dysæsthesiæ*. The causes are fever, or palsy, whence he forms two species: the first he calls **ORGANIC**, arising from some affection in the membrane of the tongue, by which relishing things, or those which have some taste, are prevented from coming in contact with the nerves; the second **ATONIC**, arising from a weakness of the nerves, without any affection of the tongue. Sauvages thinks the cause of this disease to be either in the brain, in the tongue itself, or in the passage of the lingual nerves. He forms two species: first, **FEBRILIS**, where a suppression of taste accompanies fevers, from the rough tongue; delirium, or coma: second, **PARALYTICA**, when it accompanies a paralysis of the tongue or some comatous disorder.—*Nosologia Methodica*, vol. i. 751.

**AGIAHA'LID**. See **LYCIUM**.

**AG'IS**. See **FEMUR**.

**AGITA'TION**. Exercise is sometimes useful, by agitating the whole system; and violent agitation is recommended by Bartholine in fits of tooth-ach and deafness. Agitation of mind from any cause has certainly relieved nervous complaints, and prevented the access of fevers or of spasmodic attacks.

**AGLACTA'TIO**, ( $\alpha$ , non, and  $\gamma\alpha\lambda\alpha$ , *lac*). **DEFECT OF MILK**.

**A'GLIA**, (from  $\alpha\gamma\lambda\omicron\varsigma$ , *shining*). See **ÆGIDES**.

**A'GLITHES**, (from  $\alpha\gamma\lambda\upsilon\omicron\mu\alpha\iota$ , *to be offensive*). The division or segments of a head of garlick, which we call its cloves.

**AGLUTI'TIO**, (from  $\alpha$ , priv. and  $\gamma\lambda\upsilon\zeta\omega$ , *to swallow*). A difficulty of, or impediment to, swallowing. See **DEGLUTITIO**.

**A'GME**, (from  $\alpha\gamma\omega$ , *to break*). See **FRACTURA**.

**A'GNACAT**. A tree which grows about the isthmus of Darien; it resembles a pear-tree, both as to its general appearance and its fruit, the pulp of which is said to be highly aphrodisiac. Raii Hist.

**AGNA'TA**. See **ADNATA**.

**A'GNIL**. See **INDICUM**.

**AGNI'NA MEMBRA'NA**, (from  $\alpha\gamma\lambda\omicron\varsigma$ , *a lamb*, and *membrana*, *a membrane*,) **VEL PELLI'CULA**. Actius calls one of the membranes which involves the fœtus by this name, which he derives from its tenderness. This name is adopted by Drelincourt and Bartholine. See **AMNION**.

VOL. I.

**AGNOI'A**, (from  $\alpha$ , neg. and  $\gamma\iota\gamma\iota\sigma\kappa\alpha\iota$ , *to know*). It is when a patient in a fever forgets his acquaintance. When it is joined with rigor, it is a dangerous symptom.

**A'GNUS CA'STUS**, (from *agnus*, *a lamb*, and the Hebrew term *KADASH*, *chaste*). It is called *agnus*, from the down on its surface, which resembles that upon a lamb's skin; and *castus*, because the chaste matrons at the feast of Ceres strewed them upon their beds and lay upon them. The **CHASTE TREE**, *virex agnus castus* Lin. Sp. Pl. 890. The qualities of this seed do not support its name or use. The smell is fœtid, the taste warm. It is not now used in medicine.

**A'GNUS SCY'THICUS**. The **SCYTHIAN LAMB**, called also in the Scythian language, *barametz*, i. e. lamb, or *barometz*, or *baronetz*. This sort of plant is said to be found in Tartary, Russia, &c. and is described as growing in the resemblance of a lamb. In fact, however, it is the root of a fern, covered with a whitish down, which the Tartars trim so as to represent a lamb, and sell it for a vegetating parasite animal. It would be endless to recount the ridiculous stories told of this animal plant; nor is it a part of our subject. The fern is the *poly-podium barometz* of Loureiro; the *dictisoma culcita* of Heritier. *Sertum Anglic.* Pl. 43.

**AGOM'PHIASIS**, (from  $\alpha$ , neg. and  $\gamma\omicron\mu\phi\omicron\varsigma$ , *compact*), or **GOM'PHIASIS**. A distemper of the teeth; it is when they are loose in their sockets and pained.

**A'GONÉ**, (from  $\alpha$ , priv. and  $\gamma\omicron\nu\omicron\varsigma$ , *offspring*). **HENBANE**; so named because it is supposed to occasion barrenness. See **HYOSCIAMUS NIGER**.

**AGO'NIA**, (from  $\alpha$ , neg. and  $\gamma\omicron\nu\omicron\varsigma$ , *an offspring*). See **STERILITAS**.

**AGO'NIA**, (from  $\alpha\gamma\omega\iota$ , *a combat or struggle*). **AGONY**, as when there is a struggle between life and death. To avoid this painful struggle, which has agitated the minds of the wisest and best of men, different plans have been suggested. But death is the last scene which we must all act; and, to the mind possessing an awful sense of the power and goodness of the Almighty, there is but a shade of difference between our voluntarily shortening our lives for a few hours or minutes, and the abridging half an age. Also fear and sadness of mind, with agitation.

**AGONI'STICUM**, (from  $\alpha\gamma\omega\iota\sigma\tau\alpha\iota$ , *to strive*). Galen, in speaking of Marasmus, uses this word to signify water extremely cold, which he directs to be given in large quantities in erysipelatous fevers, that it may overpower the excessive heat of the blood.

**A'GONOS**, (from  $\alpha$ , neg. and  $\gamma\omicron\nu\omicron\varsigma$ , *an offspring*, or *ovum*, *barren*).

Hippocrates calls those women so who have not children, though they might have, if the impediment was removed. In botany it means not bearing seed or fruit.

**AGO'STUS**, (from  $\alpha\gamma\omega$ , *to bring or lead*). That part of the arm from the elbow to the fingers. See also **PALMA**.

**AGRE'DULA**. A species of **FROG**.

**AGRE'STA**, **VERJUICE**, (from  $\alpha\gamma\pi\iota\omicron\varsigma$ , *wild*). The juice of unripe grapes, or the sour grape itself, called *omphax*, or the juice of the sour apple. See **MALUS HORTENSIS**.

**AGRES'TEN**. **ACID STONE TARTAR**.

AGRES'TIS, WILD, (from *αγριος*, *wild*). It is applied to vegetables that grow without cultivation (see *MALUS SYLVESTRIS*); to wild, as distinguished from tame, animals; and to express an ungovernable malignity in a disease.

A'GRIA, HOLLY, (from the same). Also a malignant pustule, of which there are two sorts; one is small, and casts a roughness or redness over the skin, slightly corroding it, smooth about its centre, spreads slowly, and is of a round figure; this sort is cured by rubbing it with the saliva before breakfast: the second sort ulcerates, with a violent redness and corrosion, so as to make their hair fall off; it is of an unequal form, and becomes leprous; its cure is the application of pellitory of the wall in the manner of a poultice.

AGRIA'MPELOS, (from *αγριος*, *wild*, and *αμπελος*, *a vine*). The WILD VINE. *Bryonia alba*. See also *BRYONIA NIGRA*.

A'GRIC. The abbreviation by which is meant Georgius Agricola de Re Metallica, Natura Fossilium, &c. Basilian, 1657, folio.

AGRICULTU'RA, (from *ager*, *a field*, and *cultura*, *tillage*). Agriculture is the art of cultivating the ground; tillage, husbandry, as distinct from pasturage. But it is not connected with medicine, except in the instance of benefit supposed to be received from vapours which arise while ground is fresh or newly turned up, particularly the light gravelly soils.

On this subject much satisfaction may be derived from the Georgical Essays by A. Hunter, M. D., second edition, in five volumes. Fordyce's Elements of Agriculture and Vegetation.

AGRIELÆ'A, (from *αγριος*, *wild*, and *ελαια*, *an olive*). See OLEASTER.

AGRIFOLIUM, (from *ακis*, *a prickle*, and *φυλλον*, *a leaf*). See AQUIFOLIUM.

AGRIMO'NIA, (from *αγρος*, *a field*, and *μονος*, *alone*). So named from being the chief of all wild herbs. COMMON AGRIMONY, called also *eupatorium Græcorum*, vel *verum*, and *hociamsanum*. *A. eupatoria* Lin. Sp. Pl. 643.

The leaves have a slight bitterish aromatic taste, the flowers are small, stronger, and more agreeable; they give out their virtues to water and to spirit of wine.

It is best used while fresh; and the tops, before the flowers are formed, possess the greatest virtue. A conserve is the best form of preparation; though the dry powder has been recommended: an infusion in water or whey is good, though now disused.

It is mildly corroborant, and recommended in humoral asthmas. It may be of some service in a relaxed state of the bronchial glands. It is used by Canadians in burning fevers, and recommended by Hill in jaundice; and by others in visceral obstructions. Alston advises it in cutaneous eruptions; and it has been considered as useful in hæmorrhages. On the whole, it is only a weak, inefficacious, astringent.

The dose is 3 i. or more. The common hemp, and Dutch agrimony, are called *EUPATORIUM*; hemp agrimony, *BIDENS*.

AGRIMONOIDES, from *αγριμονη*, and *ειδος*, *like*,) *pimpinella fol. agrim. nonnullis*. It grows on the mountains of Italy; it is of the same nature as agrimony. *A. Agrimonoides* Lin. 643.

AGRIOCA'RDAMUM, (from *αγριος*, *wild*, and *καρδαμον*, *nasturtium*). See *LEPIDIUM folio gramineo*.

AGRIOCA'STANUM, (from *αγριος*, *wild*, and *καστανον*, *the chestnut*). See *BULBOCASTANUM*.

AGRIOCI'NARA, (from *αγριος*, *wild*, and *κινναρα*, *artichoke*). See *CINARA SYLVESTRIS*.

AGRIOCOCCIME'LA, (from *αγριος*, *wild*, *κοκκος*, *a berry*, and *μηλεα*, *an apple-tree*). See *PRUNUS SYLVESTRIS*.

AGRIOME'LA, (from *αγριος*, *wild*, and *μηλεα*, *apple-tree*). See *MALUS SYLVESTRIS*.

A'GRION, *αγριος*, *wild*).

AGRIOPHY'LLON, (*αγριος*, and *φυλλον*, *leaf*). } See PEUCE-

AGRIORI'GANUM, (*αγριος*, and *οριγανον*, *marjoram*). See *ORIGANUM ANGLICUM*.

AGRIOSELI'NUM, (*αγριος*, and *σελινον*, *farsley*). See *HIPPOSELINUM*.

AGRIPA'LMA GALLIS, (*αγριος*, and *παλμα*, *palm-tree*). See *CARDIACA*.

AGRI'PPÆ. Children born with the feet foremost are so called from Agrippa, who was named *ab agro partu*, from his difficult birth. These births, though reckoned preternatural, are often more safe and easy than the natural. See *PRÆSENTATIO*. It is the name also of an ointment described by Nicolaus.

AGRIUM. An impure fossil alkali: the purer sort was called *halmyrhaga*.

AGROM. A disease of the tongue not uncommon in India; in which it becomes extremely rough and chapped. They relieve it by drinking a chalybeate fluid, or the juice of a large species of mint; or chewing the black-seeded basilica.

AGRO'STIS. See *BRYONIA ALBA*.

AGRU'MINA, *quasi agriomina*, (from *αγριος*, *wild*,) ONIONS, LEKS. See *CEPA*, and *PORRUM*.

AGRY'PNIA, (from *α*, neg., and *υπνος*, *sleep*). See *PERVIGILIUM*.

AGRY'PNOCOMA, (*αγρυπνος*, *without sleep*, and *κομα*, *lethargus*). See *COMA VIGIL*.

AGUA'RA QUI'YA. See *SOLANUM HORTENSE*.

AGUE. See *INTERMITTENT*.

AGUE DROPS. This is a medicine sold for the cure of agues, which is evidently a solution of arsenic in water. The solution is saturated, and the dose is equal to about the twentieth part of a grain. It is a powerful and useful medicine, and, in proper hands, not injurious.

AGUE CAKE. A tumour in the region of the spleen which often follows agues, and was once said to be owing to the use of the bark. It is, however, now very rare; and much more so since the bark has been generally employed.

A'GUL, an Arabic word—(*AGUL*, *a circle*). The Syrian thorn was so called, because of its pliancy, from whence they made bands of it. For its other properties, see *ALHAGI*.

AGUTIGUEPOO'BI BRASIL, (an Indian term). See *SAGITTARIA ALEXIPHARMACA*.

AGY'RTÆ, (from *αγυρις*, *a crowd of people*, or from *αγειρω*, *to gather together*). QUACKS, MOUNTBANKS, or people who go from place to place to sell medicines, were called *circulatores*, *circumforanei*, and *pharmacopole*; the last of which, though proper to any

seller of medicine, yet was strictly applied to mountebanks.

AHALOTH. The Hebrew name of lign. aloes.

AHAME'LLA, and AHMELLA. See Acmella.

A'HIUS. SALT STONE.

AHO'VAI THEVETICLU'SH, or AIICAI, HAOU-VAY. The name of a fruit in Brasil, the size of a chestnut, white, and shaped like the water caltrops; it is poisonous. The tree is as large as a pear-tree, the bark white and full of juice, the leaves are always green, the flower consists of one leaf, formed like a funnel, divided at the edge; a pistil arises from the cup, which is the fruit. Incisions in the bark emit a milky liquor that smells like garlic. It is the *cerbera ahouai* of Lin. Sp. Pl. 303. The smell is very offensive, and the nut a violent poison. The shells are, however, employed by the Brasilians as ornaments. Father Labat calls it the rattle-snake nut; as, when applied in the form of a cataplasm, it is said to cure the bites of that serpent. It is, however, suspected that the good father has mistaken the tree; since his description does not agree with the plants raised in the botanic garden at Paris.

AHU'SAL. The SULPHUR OF ARSENIC.

AI'ES. See BATTATAS.

AI'GRE DI CE'DRE. See CITREUM.

AI'LMAD. See ANTIMONIUM.

AI'PI,

AIPI'MA CO'XERA. } (Indian words). See CAS-

AIPO'CA } SADA.

AIR. See AER.

AI'RA, (*αιρα*, to take away;) so named, because it ought to be removed. See LOLIUM.

AISTHETE'RIUM, (from *αισθανομαι*, to perceive). See SENSORIUM COMMUNE.

AJUGA. The *bugula* of Jussieu. The plant used in medicine is the *A. reptans* Lin. Sp. Pl., the common bugle; *consolida media* of medical authors. It is a slight astringent, and has been styled a vulnerary. To this genus, Dr. Smith has annexed the tucrium *chamæpitys*, the ground pine. See CHAMÆPITYS.

AIX LA CHAPELLE, is a large imperial city, situated in the duchy of Juliers, on the confines of Flanders, seven leagues from Spa; it contains many springs of hot sulphureous waters, which supply a number of baths. On the vaults above the springs and aqueducts of these waters is found every year, when they are opened, a quantity of fine white-coloured flowers of sulphur, which has been sublimed from the waters. The heat of the waters of the hottest spring, Dr. Lucas says, raises the quicksilver in Fahrenheit's thermometer to 136; Mons. Monet to 146; and the heat of the fountain, where they commonly drink, to 112, according to Dr. Lucas. Sir T. Bergman obtained from a Swedish kanne 27 grains of lime saturated with ærial acid, 29 grains of sea salt, and 70 grains of mineral alkali. These waters are powerfully diaphoretic, and diuretic; and, if taken in quantity, prove purgative. Of the three hot European waters of note; viz. that of Aix la Chapelle, Bourbon, and Bath, the first abounds more eminently with sulphur, and is the hottest, the most nauseous, and purgative. The Bath waters possess the least of these qualities. In all cases it is the best to begin with small quantities, and low degrees of heat, and gradually increase them, agreeable to the effects

and constitution of the patient. In cases of dyspepsia, and foulness of the primæ viæ, they are said to be efficacious: in rheumatism, scurvy, scrofula, cutaneous diseases; in hysteria, and hypochondriasis; melancholy, stone, and gravel; in paralytic complaints, and in many other cases, they should be considered as invigorators of the system, deobstruent, and evacuant. They are improper in all hectic cases, putrid disorders, where the blood is in a dissolved state, or the constitution much broken down. The times of drinking these waters are from the beginning of May to the middle of June; or from the middle of August to the latter end of September. See AQUÆ MINERALES. See Monro's Medical and Pharmaceutical Chemistry, vol. ii. Dr. Williams on the Waters of Aix la Chapelle, &c.

AIZO'ON, (*αι*, always, and *ζωω*, vivo, to live). See ALOIDES. It is also a name for *sedum*.

AJA'VA, (Indian). So the Portuguese call a seed which is brought from Malabar, and is celebrated in the East Indies as a remedy in the colic. When the gout affects the stomach, these seeds are very effectual in dispelling the wind, and procuring speedy relief from this painful disorder; they sometimes relieve by procuring stools. The descriptions of travellers are not so minute as to enable us to refer it to its place in the Systema Naturæ. Dr. Percival takes notice of these seeds in his Essays Med. and Exp. vol. ii.

AJUBATI'PITA BRASILIË'NSIUM. A shrub bearing fruit like an almond; but it is black, and contains much oil.

A'JUGA, (*α* priv. and *ζυγον*, a yoke). See CHAMÆPITYS.

A'JUGA. REPTANS. See BUGULA.

AKMEL'LA. See Acmel'la.

AL. The Arabian article which signifies *the*; it is applied to a word by way of eminence, as the Greek *ο* is. The Easterns express the superlative by adding God thereto, as, the mountains of God, for very high, or the highest, mountains; AL may therefore relate to the word Alla, God; and alchemy may be the chemistry of God, or the perfection of chemical science. See ALCHERIA.

A'LA, AN ARM-PIT, also a WING, (Hebrew term AHLA, a leaf). It is often employed in the descriptive language of every science, for any thin expanded projections. In BOTANY, it is the two side-petals in a papilionaceous corolla: also membranes affixed to the seeds. It used to be applied to the angle formed by a branch with the stem, or by a leaf with the branch; but this is now named *axilla* or *axil*, from its similarity to the arm-pit. In ANATOMY.

A'LA AU'RIS, or *Pinna Auris*, is the upper part of the external ear.

A'LE NA'SI, or *Pinna Nasi*, the cartilages which are joined to the extremities of the bones of the nose, and which form its lower moveable part. The name also of the helenium or elecampane.

ALABA'NDICUS, } LAPIS, so called from ALA-  
ALABA'NDINUS, } BANDA, the place from whence it is taken. A blackish stone intermixed with sallow spots. It is pellucid, and looks as if it was divided by fissures into segments. Actius says, that the powder of this stone makes grey hairs black. Probably black-lead.

ALA'BARI. See PLUMBUM.

ALABA'STRON; an ointment. Myrepsus gives the formula, and says that it is the same as that with which Mary anointed the feet of Jesus Christ. ALABASTRUM also means a solid kind of white gypsum, of which utensils were formerly made; probably from Alabastrum, a town in Egypt, where it was plentifully produced.

ALACAB. See AMMONIACUS SAL.

AL'E INTERNÆ, } CLITORIDES. See NYM-  
— MINO'RES, } PHÆ.

— MAG'NÆ OS'SIS SPHENOI'DIS. The two temporal apophyses of the os sphenoides.

— PARVÆ OS'SIS SPHENOIDIS. The two thin, sharp, transverse apophyses of the os sphenoides, which form the superior orbital fissures.

ALAFI } ALCALI.

ALAFOR, and ALAFORT, }

ALAI'A PHTHI'SIS, (from *αλαιο*, blind). A wasting from a flux of humours from the head.

ALAMA'MDINA, supposed to be the alabandicus lapis.

ALA'MBIC. See ARGENTUM VIVUM.

ALAMAD. ANTIMONY. See ANTIMONIUM.

ALA'NA TE'RRÆ, (from *αλαivos*, oily, and *terra*, earth,) ENGLISH OKER; called also ALHA'NNA. It is esteemed drying and astringent; its principal use is to mix with salts in distillation, in order to keep them from melting. It is probably the *Samian stone*, and the *Terra Tripolitana*.

ALA'NDAHAL, (an Arabic term—*AHLAN*, bitter). See COLOCYNTHIS.

ALANFU'TA, (an Arabic word, from the same derivation). A vein betwixt the chin and upper lip, formerly opened to cure a fetid breath.

AL'LA POU'LI. See BILIMBI.

ALAQUE'CA, (*Indian*). A stone found in little polished fragments in the East Indies, used externally to stop bleeding.

ALA'RE EXTE'RNUM, (from *alaris*, winged, and *externum*, outward). See PTERYGOIDES EXTERNUS.

ALA'RIS VE'NA, (from *ala*, the arm-pit). The inner of the three veins in the bend of the arm, because it comes immediately from the arm-pit: this is attended with an artery, and the median with a nerve; but the outer one, as P. Ægineta long since observed, is safe for bleeding.

ALARIS, in botany. The term means growing out of the angles formed by the branches of the stem.

ALA'SET. AMMONIACUS SAL.

ALATAN. LITHARGYRUM.

ALATAR. BURNT BRASS. See ÆS USTUM.

ALATERNOI'DES, (*alaternus*, *ειδος*, likeness,) AFRICA'NA. } See CAS-

ALATE'RNUS. } SINE.

ALATI, (from *alatus*, winged). Those who have prominent scapulæ are so called, and are subject to consumptions; since, from the pressure of the muscles in consequence of this disadvantageous attachment, the sides of the sternum are compressed.

— PRO'CESSUS, or ALA'RES. The wing-like processes of the os sphenoides.

ALAU'RAT. See NITRUM.

ALBA SIMPLEX. See OCIMASTRUM.

ALBADA'RA (from ALBADAR, an Arabian word). See SESAMOIDEA.

ALBAGIA'ZI. See SACRUM OS.

ALBAME'NTUM, (from *albus*, white). See ALBUMEN OVI.

ALBA'NUM. SALT OF URINE.

ALBA'RA, (from ALBAHRAH, a Chaldaean word). A species of the white leprosy, see ALPHIUS. It also signifies the white poplar. *Albarus nigra* is the *lepra Græcorum*. Avicenna calls the *lepra ichthyosis* by this name.

ALBA'TIO, ALBIFICA'TIO, (from *albeo*, whitening,) called blanching of metal.

ALBE'DO, (from *albis*,) WHITENESS. In urine is observed four sorts of whiteness, viz. the crystalline, the snowy, the limy, and the limpid.

ALBERAS. White pustules upon the face. See ALBORA. It is also a name given to staves-acre, because its juice is said to remove these pustules. See STAPHIS AGRIA.

ALBE'STON. QUICK-LIME. See CALX.

ALBETAD. See GALBANUM.

ALBI. SUBLIMATE. See MERC. CORROSIVIS ALB.

ALBICA'NTIA, CORPORA, (from *albeo*). Willis's glands. See CEREBRUM.

ALBIMEC. ORPIMENT. See AURIPIGMENTUM.

ALBINUM, (from the whiteness of its blossom). See GNAPHALIUM.

ALBIN INS. The abbreviation for Albin Eleazer, a natural history of insects. London, 1720, 4to.

AL'BIR. Pitch from the bark of the yew-tree.

AL'BOR URINÆ. See URINA.

AL'BOR O'VI. WHITE OF AN EGG. See ALBUMEN OVI.

AL'BORA. A sort of itch, or rather leprosy. Paracelsus says, it is a complication of the morphew, serpigo, and leprosy. When cicatrices appear in the face like the serpigo, and then turn to small blisters of the nature of morphew, it is the *albora*. It terminates without ulceration, but by fetid evacuations in the mouth and nostrils: it is also seated in the root of the tongue. Internal medicines, as well as corrosive ones, are forbidden.

ALBO'RCA. MERCURY. See ARGENTUM VIVUM.

ALBOT. See CRUCIBULUM.

ALBOTAT. CERUSS. See PLUMBUM.

ALBOTIM, or ALBO'TAI. See TEREBINTHINA.

ALBOTIS. See TERMINTHUS.

ALBUGINEA, vel TENDINO'SA TUNICA. The inner proper coat of the testicle, named from its white and transparent colour. It is a strong, thick, white membrane, smooth on the outward surface, rough and uneven on the inner: into the upper part of this membrane are inserted the blood vessels, nerves, and lymphatics, which send branches into, and receive them from the testicle.

This coat being distended, is the cause of that pain which attends an inflammation of the testes.

*Albuginea* is also the name of the *adnata*, q. v.

ALBUGINO'SUS HU'MOR. See OCULUS.

ALBU'GO CORA'LLII. A name of the magistery of coral, which it hath obtained from its whiteness.

ALBU'GO OCULORUM. WHITE SPECK ON THE EYES. The Greeks generally named it *leucoma*: the Latins and ancient authors, *nubes*, *pterygium*, *pannus oculi*, *onyx*, *paralamphsis*, *argema*, and *ægides*; Dr. Wallis

the albuginous, or pearly corneal speck. The French name it *tache blanche*, if it shines; the Latins, *margarita*; the Greeks, *παρυλαμπσις*; the French, *perle*; Dr. Cullen, *caligo cornea*. See ACHLYS.

All cicatrices appear white in the black part of the eye, and astringents thicken them.

It is sometimes called *nubecula*, when superficial; and *albugo*, when deep: when the speck appears of a shining white, and without pain, it is called by some a cicatrix; when of an opaque whiteness, an *albugo*: seated superficially, it hath been termed a speck; and more deeply, a dragon; when it projects a little, it is called a pearl.

The disease consists in a chronic inflammation of the eye, from erosion, measles, small-pox, wounds, burns, &c.

When deep, the cure is difficult; when the consequence of a wound or ulcer, it is rarely cured; when the natural shape of the eye is altered, the prognostic is unfavourable. The *albugo* which follows an inflammation generally disappears spontaneously.

The aqua cupri ammon. alone sometimes succeeds in the cure; and in general saturnine and mildly astringent or stimulant applications are useful. When the film is very tough, and the eye not inflamed, common glass finely levigated may be blown upon it through a quill, and repeated once in a day or two. Dr. Kirkland thinks, that, in general, nature, assisted by strengthening the eye with cold water, will affect the cure. A single drop of laudanum, dropped into the eye night and morning, will often cure it. Boerhaave prescribed the repeated use of calomel and cathartics to dissolve the lymph, and free the cornea from leucoma. See UNGUIS. See Kirkland's Inquiry, vol. i. p. 492. Bell's Surgery, iii. 356. Wallis's Nosology of the Eyes, p. 134. White's Surgery, 228.

A'LBUM BALSAMUM, (from ALBUM, a Chaldæan term). See CAPIVI BALSAMUM. A balsam also so called is thus made: R. Aquæ lythargyri acetati ad consist. mellis evaporat. et ol. rosar. āā p. æq. m.

A'LBUM CANIS, } THE WHITE DUNG OF DOGS;  
——— GRÆCUM, } also called *spodium Græcorum*, *nil album*—*gryseum*, *cynocofrus*. It is slightly stimulant and discutient, and was formerly applied to the outside of the throat in quinsies, being first mixed with honey.

A'LBUM HISPANIÆ, et HISPANICUM. SPANISH WHITE. It is also called *bianca Alexandrina*. It is made from tin and bismuth, in the same manner that ceruss is made from lead, and is a cosmetic.

ALBUM JUS. WHITE BROTH. Boil whiting, had-dock, cod, or any similar fish, in water, with a little oil; a small quantity of anised and leeks. When the fish is parboiled, add a little salt.

A'LBUM NIGRUM. MOUSE-DUNG.

A'LBUM OLUS. LAMB'S LETTUCE, or CORN SALAD. See LACTUCA AGNINA.

ALBUMEN O'VI, WHITE OF EGG; called also *albumor* and *albor ovi*, *ovi albus liquor*, *ovi candidum*, *albumentum*, *clareta*, &c.

The white of an egg is a pellucid viscous liquor, thinner towards each end, and thicker in the middle. That part which is more dense and close than the rest is called *gallatura*.

The industry of later physiologists has discovered three different kinds of albumen in each egg, of different densities. The external is the most liquid; the second is less so, and the third still less fluid. It is to this third portion that the shape of the albumen is confined; the others surround the yolk: this consists of two segments of spheres of unequal diameters, applied to the sides of the yolk, and connected with it by a somewhat denser albuminous process, *near* each extremity; though not, as has been represented, at the poles. These albuminous processes are styled *chalazæ*. Each of the portions of this internal albumen is penetrated by a convoluted cord: that, on one side, is membranous; the other, vascular. The former is contiguous to the pellicle of the yolk; the latter, analogous to the umbilical cord in the mammalia, forms the communication between the albumen and the yolk.

The albumen of the egg, in its early period, is less homogeneous than at a later; since, in boiling, it concretes into a curdly fluid. Some water escapes from it, and is collected in a pellicule, on the top; and it is probable, though by no means certain, that some oxygenous gas is absorbed. It is said to be destined for the nourishment of the chicken; but, in the process of incubation, it is not materially diminished in quantity, and we know that the yolk is the real nutritious substance, and is taken into the body of the chicken at the end of the period of incubation. A milder nourishment may probably be required in the early stages: nor is it very improbable that the three kinds of albumen may be designed as nourishment for the chicken at its different ages, and the waste repaired by the absorption of humidity. If this is prevented, the progress of the embryo is checked, and the egg continues in its first state.

The albumen is peculiarly mild, resembling the serum of the blood, which is a watery fluid, with an admixture of the gluten; a portion of which appears to be chemically combined, and the larger part mechanically mixed. It is soluble in hot or cold water, coagulated by heat of 165° of Fahrenheit; by acids, and by alcohol. When diluted by ten times its weight of water, heat does not coagulate it; but acids and alcohol continue to produce this effect until it is more largely diluted. In the coagulation, the bulk is not increased; and the coagulum neither absorbs nor emits air. The cause of the coagulation is probably the addition of caloric; but to ascertain this idea, which is originally Scheele's, the capacity of the albumen in each state for heat should be ascertained.

Albumen naturally contains a proportion of soda and a little sulphur. In water of 80°, it soon becomes putrid, and exudes through the broader end of the shell. Alkalis and alkaline earths dissolve it; disengaging some ammonia, in consequence of its decomposition. A solution of tannin precipitates albumen in the form of a yellow precipitate, of the consistence of pitch; and, however minute the proportion of albumen combined with water may be, it is discoverable by means of tannin. When dissolved by alkalis, and precipitated by acids, its qualities are altered. When coagulated, water no longer dissolves it, but mineral acids have this power, and tannin only will precipitate it: alkalis have no effect. In its analysis, it resembles the gluten of the

blood, but contains a less proportion of azote than the fibrin: the other ingredients are carbone and hydrogen. See BLOOD and TANIN.

The yolk of the egg differs in appearance, rather than its nature, from the albumen. It has a portion of the gluten, and contains a resinous, or rather an oily fluid. By heat, the oil is entangled in the coagulable substance; but a portion may be expressed, and is employed as an antiphlogistic remedy against sun-burns. The colouring material is not known. Fourcroy supposes it to be iron; but it is more probably sulphur, as a putrid egg exhales a strong hepatic gas. The shell of the egg consists chiefly of carbonat, and phosphat of lime, with gelatinous matter. The membrane that lines it, though apparently dense, suffers some fluids to escape, and some gases probably to be absorbed, since acrid and deleterious vapours destroy the chick. This membrane is a part of the albumen, and, of course, a part of the embryo, since its vessels may be injected from those of the chick.

Eggs are chiefly employed as nourishing substances. In the arts, the albumen forms, with quick lime, a strong cement for china; and, diluted with water, it has been used to lessen the rigidity of the tendons; in pharmacy the yolk is employed as an intermede, to mix or suspend oils, balsams, and resins in water. The oil of the yolk we have already mentioned.

As a nutritious substance the yolk is the most distinguished. It is not certain that the albumen abounds in nourishment. It is very bland when fresh, and highly deleterious when in the slightest degree putrid. Even in its best state it disagrees with many stomachs; producing eructation, sickness, and sometimes erysipelatos eruptions. The yolk is very nourishing; but, when firmly coagulated by boiling, it is slow of digestion. It was some years since in high reputation as an aliment for weak stomachs. A fashionable physician ordered it, in one instance, and every one took it. The consequence might be easily supposed; but the practice continued while the physician was fashionable. In jaundice and liver complaints, a fresh unboiled egg has been recommended every morning, and it is said with success: we know not for what reason, except that it is yellow. In general, it is useful in weak stomachs, as it contains much nutriment within a small compass; and, though the hard egg is slow of digestion, we have not found it increase hectic exacerbations. We shall see that *slow* and *difficult* of digestion are not synonymous. Nature seems anxious to retain the food in the stomach; and the best digestives are those which *retard* the process. Too rapid a digestion is, in many views, productive of inconvenience. See DIGESTION.

The eggs of different birds do not differ essentially: those of geese and ducks are said to be the most gross and alkaliescent: those of pea-hens and gallinas the least so. The latter have certainly less flavour.

ALBUMOR. See ALBUMEN OVI.

ALBURNUM, (from *albus*, *white*). The softer and paler part of wood next the bark: artificers call it the sap, to distinguish it from the heart, which is deeper coloured, and harder. See SANTALUM ALBUM.

ALBUS LIQUOR. See ALBUMEN OVI.

ALBUS ROMANUS PULVIS. See MAGNESIA

ALBA.

ALBUS, besides its well known signification to express white, is also the name of a fish. See CAPITO LACUSTRIS.

A'LCAHEST, or A'LKAHEST. The UNIVERSAL MENSTRUUM, or DISSOLVENT. A name first used by Paracelsus, and derived from the German words AL and GEST, i. e. *all spirit*. Van Helmont borrowed the word, and applied it to his invention, which he called the universal dissolvent.

ALCAHEST is also a name of the liquor of flints, and of all fixed salts volatilised.

A'LCALI, or A'LKALI, (of *al* and *kali*, i. e. the essence or the *whole* of kali, the plant from which it was originally prepared, though now derived from plants of every kind). Alkaline salt is called *alafi*, *alafort*, and *calcadis*. As alkalis effervesce with acids, all volatile or fixed salts, and all terrestrial matters which ferment with acids, are called *alkalis*.

*Alkalis* are mineral, vegetable, and animal, which three were particularly distinguished by the term, adding to it the peculiar epithet; but the College of Physicians of London have now distinguished them by three different appellations; calling them NATRON, KALI, and AMMONIA; but they are either earthy or saline.

The former terms are now indeed found to be peculiarly improper; since the kali is discovered in some minerals, even in some granites, and the ammonia is obtained not only from plants, but seeds. The soda or natron occurs both in vegetables and animals. Besides these, there are several earths, which, in their more general properties, resemble alkalis; particularly lime, magnesia, barytes, and strontian.

Earthy *alkalis* are those substances which of themselves scarcely dissolve in pure water; but if added to acids, form a neutral. Of this sort are *chalk*, *limestone*, *crabs'-eyes*, *oyster-shells*, *egg-shells*, &c. Thus, if pure water is acidulated with oil of vitriol, it effervesces, if you scrape chalk into it; and during the effervescence, the water hath a brisk taste; when enough of chalk is added, the acidity is lost.

Their taste is in general acrid and urinous; they change the blue colours of vegetables to a green, destroy the taste and other properties of acids, and dissolve with peculiar facility in water. As the volatile alkali is known to be a compound of azote and hydrogen, it is probable that the fixed kinds are formed of similar ingredients. Thus hydrogen, with lime, may form pot-ash; with magnesia, soda. Some experiments supposed to prove these combinations, have been found fallacious; yet the principle is highly probable.

The saline *alkalis* are fixed and volatile. The latter of which differs from the former only in volatility and its consequence; the volatile alkali rises sooner than the rectified spirit of wine.

Tachenius is said to have first made the fixed vegetable *alkali*: he established the general use, but it was known long before his time. A fixed *alkali* is the basis of sea salt.

— VEGETABLE. This was formerly prepared from wormwood, and named SAL ABSINTHII; but the College of Physicians have supplied its place with the KALI PREPARATUM, which is made in the usual method of dissolving, filtering and crystallising the salts of vegetable. The same salt may be prepared

from tartar, burnt till it becomes of an ash colour : and, indeed, of all the substances from which a fixed alkaline salt is obtained, tartar yields the largest quantity, and with the least trouble. The college has ordered the solution of potash to be set apart a whole night for the neutral salts, which are part of the composition, to crystallise, but that is not sufficient ; for, in order to have the alkali in its purest state freed from those salts, which is their intent, the solution will require to be exposed to crystallisation three times, at least : otherwise it will retain too great a share of vitriolated tartar. *Observations on the Pharmacopœia Collegii Regalis, &c. London, 1788.*

The quantity of pure potash usually employed in commerce, is estimated by Vauquelin according to the following table :

	Potash.	Sul. of Pot.	Muri. of P. A.	Insol. Car.	Ac. & W'
Russian potashes	772	65	5	56	264
American ditto	857	154	20	2	119
Pearl ashes	754	80	4	6	308
Potashes of Treves	720	165	44	24	119
Dantzic ashes	603	152	14	79	304
Potashes of Vosges	444	148	510	34	304

**ALCALI MINERAL.** This MINERAL FIXED ALKALINE SALT may be procured from sea salt, and from the waters of many springs, either by distillation of the acid, or the superior affinity of the vegetable fixed alkali. This alkali differs from that of vegetables, by being milder, and less acrid to the taste ; melting more easily in the fire ; requiring more water to dissolve it ; in its concreting into crystalline masses on evaporation after solution in water ; not becoming liquid by exposure to the air ; and in being a less powerful solvent of the stone in the bladder. As a less deliquescent salt, it is best adapted to form pills. The crystals are prismatic, resembling those of the natron vitriolatum. With this mineral alkali the Spanish soap is made. This salt, joined with the *vitriolic acid*, forms the NATRON VITRIOLATUM ; with the *nitrous*, NITRUM CUBICUM ; with the *muriatic*, SEA SALT ; and with *vegetable acid*, the NATRON TARTARISATUM. The Egyptian soda was usually reckoned the strongest ; but it is usually mixed with sea salt, with sand and a kind of steatite ; then the Spanish (barilla). After this came the trona from Tripoli, and then that prepared from different species of kelp. We have now, however, an ample supply from another source. In preparing the oxygenated muriatic for the purposes of bleaching, the muriate of soda is decomposed by the sulphuric acid. The sulphate of soda is afterwards decomposed in different ways ; for which see Accum's Chemistry.

**VEGETABLE.** The VEGETABLE ALKALI, OR POTASH, and the MINERAL ALKALI, OR SODA, possess the general properties of alkalis ; and most inflammable substances are acted upon by them. They melt in a moderate heat ; and in a stronger they are volatilised : in the dry way they dissolve earths and the calces of metals.

Fixed alkaline salt is obtainable from sea salt and nitre, and from all vegetables, except perhaps some of the volatile acrid kind, which impress the nose sharply with their scent, such as mustard seed, garlic, &c. ; these contain parts that are volatile, and become volatile salt. The fixed salt of some plants vary greatly from one another, in strength, &c. if taken in the state wherein they are first extracted from the ashes : they

sometimes contain some neutral salt of the vitriolic or of the muriatic kind, which are discovered by shaking them in a vial, with equal part of spirit of wine, the fluid with neutral salt becomes milky. Sometimes a bitter crystalline hard salt, that is neither acid nor alkaline, but a mixture of earthy and alkaline neutrals, is found among the fixed alkaline salt ; readily separated by means of cold water, in which it will not dissolve. This hard salt is never met with in making the salt of tartar, but in potash it is often found. The salts of the leaves, and other herbaceous parts of plants, are more difficultly brought to a state of purity than those of the more woody and compact portions, a portion of the oil being so tenaciously retained : some endeavour to retain this oil in the salt, by burning the vegetables in a smothering heat until they are reduced to ashes. They do this to render the salt more mild, or to combine the virtues of the oil ; but the mineral alkali is sufficiently free from acrimony to sit easy on the most irritable stomach, when administered in the usual modes ; and the empyreumatic oil, retained, will occasionally, it is supposed, excite nausea. To this, however, there are objections. Some practitioners have thought that saline draughts made from the alkali, which still retained a portion of the oil of wormwood, sat more easily on the stomach : we are confident that the taste was more pleasing. In other instances, the advantages are less equivocal : we allude to the ashes of broom and tobacco, which certainly possess a stronger diuretic power from the oil adhering to the salts.

In estimating the strength of alkali it has been usual to add the muriatic acid, and for each dram saturated, so many one-sixteenths of pure alkali were allowed. Alkalis, when pure, from whatever plants obtained, are entirely the same. What was, however, formerly styled pure alkali, is not so in the modern acceptation of the term. Mild alkalis are carbonated ; that is, neutralised by carbonic acid. When exposed to heat, or combined with quick lime, which has a greater affinity for the carbonic acid than alkali, they become what has been styled caustic : in reality they are pure ; and, when a mild alkali is united with a stronger acid, the separation of the carbonic acid, in the form of gas, occasions the effervescence. As a medicine, if largely diluted with water, and taken in bed or a warm room, vegetable fixed alkali promotes perspiration ; but its tendency is more directly to become diuretic, and this is promoted by the patient resting in a cool situation. In this way it appears sometimes slightly laxative ; and is useful to the studious, in whose stomachs acids usually abound. It destroys acidity in the primæ viæ, converting them into a mild aperient salt, and thus removes a cause of many chronic diseases. It loosens the texture of calcareous concretions by strongly attracting their air ; and when pure, this power is increased. In those flatulent disorders which arise from a defective bile, it affords great relief.

The dose may be from gr. ij. to ℥ j. twice a day, but always plentifully diluted ; the dose of ℥ j. should be mixed with at least 3 x. of water. Considerable doses may be long continued, as is evident in those who take the aqua kali puri to remove calculous complaints ; but the tone of the stomach, and the powers of digestion, are sometimes destroyed by large doses and long use. It was supposed that alkalis thinned the blood ; and numerous are the diseases attributed by the humoral pathologists to alkaline acrimony. It has indeed been

suspected in scurvy, but seems to take place only in a small degree; and the alkali is the volatile in the form of an ammoniacal neutral. Fixed alkalis have been generally found diuretic; and perhaps in a greater degree when not neutralised in the stomach, or when defended from its acid by bitters. On the contrary, they are laxative only when they meet with such an acid as the stomach affords. The absence of an acid also seems necessary to their operation, as lithontriptics.

The fixed alkalis have lately been recommended in cutaneous complaints, and have been employed with some success. It is probable, however, that they chiefly act by correcting an acidity in the stomach, which occasions them; or by the discharge of urine which they excite. It is singular that acids have a similar power; nor does the distinction of the species adapted to each appear in any medical author. In general, the acids seem best adapted to the cases where the eruptions occur in worn-out constitutions, and are of the tettery kind: the alkalis in the drier, scurfy eruptions. Yet even this distinction will not hold in every instance; nor indeed in our hands have the alkalis been eminently successful.

The fixed alkali has been sometimes thought useful in adding to the power of different menstrua, or in correcting the drastic acrimony of some resinous purgatives. With bitters, it has been supposed to be a febrifuge; and with camomile flowers, it has been in high esteem as a remedy for intermittents. It seems to produce some chemical change on bitters, as it reddens the infusions of bark and of rhubarb: and in many cases of dyspepsia appears an useful addition to astringents or tonics.

Externally, it is used in the form of a lotion in rachitic cases, as a stimulus in indolent ulcers, and in some cutaneous eruptions. The solution soon abates the pain arising from the stings of bees and wasps, and has been applied in burns. With sulphur, under the title of *hepar sulphuris*, it is also often useful. See *KALI SULPHURATUM*.

The fixed alkalis have obtained a variety of appellations, partly from fancy, but more frequently from the ignorance of chemists; who, having obtained these salts from different sources, supposed that they had discovered a new substance.

The fixed vegetable alkali has been styled *Cineres Russici* and *clavellati*, *pot blanch*, and *pearl-ashes*, *alkahest glauveri marcroft*, *cendres gravellées*, *sol tartari*, *sal absynthii nitrum fixum*, *cassob* and *lapis infernalis*. It has been more lately styled by Dr. Black, *lixiva*; by the French chemists, *potassa*; by the London College, *kali*; by others, *oleum tartari* and *lixiva tartari*.

The fixed mineral alkali has been styled by Dr. Black, *trona*, from a district of Tripoli where it abounds; *soda*, by the French chemists and the Edinburgh college, &c. *Anatron*, also called *nataron*, *anachron*, *soude blanche*, *nitrum antiquorum*, *litron*, *aphronitum*, *baurach*, *sal alkalinus salis marini*, *barilla*, *soda*, *salitron*, *bariglia*; *anatron*, *anatronum*.

**ALKALI VOLATILE.** **AMMONIA**, called also *Asanon*. **VOLATILE ALKALINE** salt is either in a dry or liquid form; when dry, it is called salt; when liquid, water; the salt is obtained by sublimation, the water by distillation.

The volatile alkaline salt hath been chiefly obtained from the horns of deer, by distilling them in large iron

pots, with a fire gradually increased to a strong red heat; but a similar salt, liquor, and oil, may be extracted from all animal substances except fat, from blood dried by a gentle heat, from urine first evaporated to the consistence of honey, and subjected to putrefaction. Urine, distilled with the addition of quick lime, yields an extremely pungent spirit. Ivory, and the bones of animals, are used for this purpose; bones are, indeed, preferable to hartshorn; as the salt and spirit of bones require less rectification, are less disgusting to the stomach, and the spirit retains its limpid appearance longer than that from horns: when bones are used, their fat must be extracted first by long boiling. Wood-soot affords a salt liquor and oil, not differing from those of hartshorn, except as it is less easy to rectify. From crude sal ammoniac, mixed with any fixed alkaline substance, the volatile alkaline salt of the sal ammoniac is obtained, and with very little trouble rendered perfectly pure; the spirit of sal ammoniac is free from the inconveniences which attend those spirits obtained from horns, ivory, bones, &c.

*LIQUOR, olim SPIRITUS, SAL, et OLEUM CORNI CERVI.*

*The liquor, salt, and oil of hartshorn.*

These preparations are brought to us by the practical chemists in a state sufficiently pure for common purposes, and the process will be found in the commonest chemical author.

As the fixed alkalis, from whatever plants they are prepared, do not essentially differ when pure, so the volatile is the same from every source. The crude sal ammoniac, as it is styled the muriated ammonia, is prepared in large quantities in Egypt from camel's dung, and other animal excrementitious fluids. This affords the ammonia usually employed, and it is preferred, in general, as a medicine. That from the hartshorn has always a little of the animal oil; which, though better adapted as a smelling salt in some hysteric affections, is less agreeable to the stomach.

The volatile alkaline salt is very penetrating and pungent to the smell and taste, and is the only concrete salt that in its pure state emits sensible effluvia; it dissolves oils, resins, fats, &c. more slowly than the fixed alkalis, on account perhaps of its not being susceptible of any considerable heat by which its solvent power might be promoted. In the bodies of animals it operates more powerfully than the fixed alkaline salt, and is more disposed to pass off by the pores of the skin, and acts more remarkably on the nervous system. It is peculiarly useful in lethargies, apoplexies, hysteric and hypochondriac disorders, languors, head-ach, flatulencies, and other symptoms attending these complaints; in languors and faintings this salt often gives immediate relief; in low fevers it is an useful remedy; it relieves rheumatic pains, particularly joined with blisters, and purges.

The fanciful idea of its promoting putrefaction has prevented its being employed in putrid fevers; but when a quick, active stimulus is required, no medicine is preferable; and the very small quantity given can have no bad effect on the whole mass, even were its septic power less equivocal. When united with the vegetable acid in the aqua ammoniæ acetatæ, it is eminently useful, if given in a sufficient dose, which is at least half an ounce, or six drams.

Externally it is used as a stimulant, in the form of

the volatile liniment, united with oil, or in that of a soap, styled in common language opodeldoc.

The dose of volatile alkaline salts may be from gr. ij. to ℥ ss. given in a draught or in a bolus ; in the latter form, to prevent the pungency of the salt from affecting the throat, it may be proper to mix it with a solution of gum tragacanth, or some other mucilaginous substance. See AMMONIA.

SP. SAL. AMMON. DULC.—now called SPIRITUS AMMONIÆ.

DULCIFIED, OR SWEET SPIRIT OF SAL AMMONIAC.—SPIRIT OF AMMONIA.

Take of a fixed alkaline salt ℥ vi. of crude sal ammoniac ℥ iv. of proof spirit lb iij. and mix ; with a gentle heat draw off ℥ i. ss. ; the dose is from fifteen drops to a dram or more.

The volatile *alkalis*, not caustic, do not unite with vinous spirits by simple mixture ; yet a solution of them in sp. vin. R. is obtainable by distillation. This preparation is deservedly in great esteem both as a menstruum and a medicine ; it is a solution of alkaline salt in spirit of wine, for though proof spirit is used, its water does not rise ; it only serves to facilitate the action of the pure spirit upon the ammoniac salt ; it might, perhaps, for some purposes, such as making the sp. ammon. comp. &c. be more advisable to make a dulcified spirit with the pure liquor of ammoniac, for it may be mixed at once with rectified spirit of wine in any proportion, without the hazard of separating the volatile *alkali* ; and readily form an extemporaneous dulcified spirit of sal ammoniac :

Take the spirit of sal ammoniac prepared with quick-lime, rectified spirit of wine, of each a pound.

SPIRITUS VOLATILIS CAUSTICUS, vel

SPIRIT. SAL. AMMON. CUM CALCE. VIV. PPT. Now AQUA AMMONIÆ PURÆ.

This spirit, prepared with quick-lime, is thought to be too pungent and acrid for internal use ; but in the dilute state of administering this medicine, it is as safe as that prepared with an alkaline salt. It is an excellent menstruum for some vegetable substances ; and when saturated with such ingredients, is so sheathed as to be as safe as the other. If this spirit is not pure, a slight proportion of it will make lime-water turbid.

The aqua ammoniæ puræ appears in many cases preferable to that prepared with an alkaline salt. It is better suited for the sp. ammon. compositus, and sp. ammoniæ fœtid. as being perfectly miscible with the sp. vini rect. in any proportion, without any separation of its volatile alkaline part, and as being a more powerful menstruum for some oils, difficult of solution. The EAU DE LUCE, for example, is made with the aqua ammoniæ puræ, et ol. succin. rect. ; but the oil must be rectified until it hath lost its smell, and is become limpid, and then the process will be the following :

R. Ol. succin. rect. ut supra gtt. xxxvi. alcohol. vini ℥ ss. bene misceantur, et adde paulatim aquæ ammoniæ puræ, ℥ vi. This appears milky ; but if required limpid, it may be made so by distillation ; or if it is only designed for smelling, it may be tinged of a fine blue colour, with a drop or two of a solution of copper. See Malouin's Chimie Medicinale.

The College of London give the following prescription for making the EAU DE LUCE, under the title of SPIRITUS AMMONIÆ SUECINATUS ; *Succinated spirit of*  
VOL. I.

*ammonia*. Take one ounce of alcohol ; water of pure ammonia four ounces ; rectified oil of amber one scruple ; soap ten grains : digest the soap and oil of amber in alcohol, until they are dissolved ; then add the water of pure ammonia, and mix them well by shaking :—it is chiefly used externally. There is a great nicety in this preparation, known only to those who prepare it, and which chemists have not attained ; but this accuracy does not affect its medical virtues. The chief imperfection is, that the ingredients separate, but they will unite again by agitation.

Divers mixtures of volatile and vinous spirits, flavoured with aromatic and other oils, or tinctured with different ingredients, according to the intention of the prescribers, have been, and yet may be, used with great advantage. Of this kind are the following :

Sps. AMMONIÆ COMPOSITUS, instead of the sps. volatilis aromaticus.

R. Ol. nucis moschatæ et ol. limon. essent. āā ℥ ii. sp. ammon. ℥ iij. m. Distil these with a gentle heat. This is from the Pharmacop. Collegij Lond. 1788.

By this method a volatile oily spirit may be prepared occasionally, and at pleasure adapted to particular purposes, by choosing an essential oil proper for the intention ; thus in *hysterical cases*, where the uterine excretions are deficient, a sp. ammon. comp. may be made with the oils of rue, savin, penny-royal, asafoetida, &c. For *weakness of the stomach*, the oil of mint may be taken ;—for a *cephalic*, the oils of marjoram, lavender, and rosemary ; against *fainting and coldness*, the oil of cinnamon ;—to remove flatulencies, the oil of aniseeds and sweet fennel. The spirits thus made by simple mixture, or by dropping essential oils into sp. ammon. with which they easily mix, are nowise inferior in medical efficacy to those prepared by distillation, though the tinge which they receive from the oil may render them to the sight less pleasing.

The small quantity, however, of any medicine which can be thus conveyed into the system, can have no very powerful effect ; while, as a warm stimulant, it greatly assists the power of other medicines. The ammoniated alcohol conveys very rapidly the effects of aromatics, as in the spiritus ammoniæ C. of the London Dispensatory ; the alcohol ammoniatum aromaticum of the Edinburgh ; or the spiritus alkali volatilis of the Dublin. The compound tincture of castor, the volatile tincture of guaiacum, and the ammoniated tincture of valerian, are, in their respective uses, excellent medicines. The ammoniated tincture of bark is less useful ; as from bark we do not want an immediate effect, and the quantity of this medicine introduced is inconsiderable. The objection does not apply to the volatile tincture of guaiacum, as the menstruum, in this instance, directs and increases the power of the medicine.

SOME VEGETABLES are considered of an alkalescent nature, as they do not become acid by putrefaction ; and from them no vinous spirit can be procured by fermentation ; to this class belong most of the acrid aromatics ; some of which are the alliaria, allium, arum, asparagus, brassica, capsicum, cardiaea, centaurium min. cochlearia, cepa, nasturtium aquat. et hort. porrum, raphanus com. et rusticanus ; ruta, sinapis, &c.

The signs of ALKALINE ACRIMONY in the blood, viz. thirst and desire of sour drinks, loss of appetite, and aversion to alkalescent food, nidorous eructations, putrid

ulcers on the lips, tongue, and other parts in the mouth, bitterness in the mouth, sickness in the stomach, and a frequent diarrhœa, a sense of heat, lassitude, and general uneasiness, a dissolution of the texture of the blood, the urine high-coloured and red, in fact only show that it exists in the stomach.

**ALKALINE GAS.** This is only volatile alkali in the form of air, and has never yet been applied to medical uses.

**ALKALINE EARTHS.** Many of the earths are absorbents; but some approach so nearly to an alkaline nature, that they have obtained this appellation more pointedly. These are magnesia, lime, barytes, and strontia: all but the last are used in medicine; the barytes, in composition only, with the muriatic acid.

**ALKALI** in botany. See **SALICORNIA**.

**ALKALI'NA, INFUSIO.**

R. Kali  $\bar{z}$  ss. croc. Anglic.  $\bar{z}$  ss. rad. liquorit. rec.  $\bar{z}$  ij. aq. font. bullientis lb ij. infund. per horas vi. vel vii. et cola. Vel,

R. Fol. absinth. vulg. sicc.  $\bar{z}$  ss. kali pp.  $\bar{\theta}$  ij. infund. in aq. font. bullient.  $\bar{z}$  xij. colaturæ; adde aq. juniperi  $\bar{z}$  ij.

These are useful methods of administering the fixed alkaline salt; small doses may be given warm every three or four hours, interposing occasionally a purgative, when such medicines are required. If intermitting fevers return, this method, for a few days, is an excellent preparation for the bark.

**ALKALISA'TIO, ALCALISATION.** The impregnating any thing with alkaline salt.

**ALKALI'NUS SAL, SA'LIS MA'RINÆ.** See **ANATRON**.

**ALCA'NCALI.** See **ANGELOCALOS**.

**ALCA'NNA**, (Indian word). See **ICHTHYOCOLLA**, **ANCHUSA**, and **LIGUSTRUM INDICUM**.

**ALCA'RNI**, (an Arabic term). A name of a confection made by Messuc.

**A'LCARA.** See **CUCURBITA**.

**A'LCE**, (from *αλκν*, strength). The **ELK**. It is a large animal of the deer kind, met with in Muscovy, Germany, and very cold countries. The hoof of the hind foot on the left side hath been celebrated against epilepsies, from a ridiculous opinion that the *elk* is himself subject to disorders of this kind, and prevents or removes them by scratching his ear with his hoof.

**ALCE'A**, (from *αλκν*, strength,) so called, on account of its force in expelling poisons.

**ALCE'A VULGARIS MAJOR.** See **DORONICUM GERMANICUM**.

**ALCE'A**; **VERVAIN MALLOW.** See **MALVA VERBENACEA**.

**ALCE'A INDICA.**

**ALCE'A ÆGYPTIACA, VILLOSA.** } See **ABELMOSCHUS**.

**A'LCEBAR.** See **AGALLOCHUM**.

**A'LCEBRIS VIVUM**; i. e. **SULPHUR VIVUM**.

**ALCE'DO.** A bird called the **KING'S FISHER**. It is also called *ispida*, *halcyon*, *alcyon*, *fluvialis*, *fiscator regis*. It is said to make its nest in the sea, and then it is a sign of fair weather, whence the word *halcyon days*—calm and peaceable times.

**A'LC'HABRIC.** See **ALKIBRIC**.

**A'LC'HACHIL.** See **ROSMARINUS**.

**A'LC'HARITH.** See **ARGENTUM VIVUM**.

**A'LCHEMIA, A'LC'HIMIA, or A'LC'HYMIA,**

**A'LKIMA, ALCHEMY.** That branch of chemistry which relates to the transmutation of metals into gold; the forming a panacea, or universal remedy; an alkahest, or universal menstruum; an universal ferment; and many other absurdities. The pursuits of the alchemists obtained more attention, as they offered two of the most powerful attractions—riches and immortality. With the former we have no concern; but it is necessary to remark, that the fifteenth century was the era when these fancies began to influence medicine. To the alchemists we are indebted for our mercurial and antimonial preparations; and their pretensions—in some measure their success—produced a considerable revolution in medicine, by undermining the authority of Galen, till that time supreme. Basil Valentine seems to have been the earliest of these authors; and his *Curus Triumphalis Antimonii*, though abounding in enthusiastic reveries, displays reflection and knowledge. Paracelsus was an ignorant boasting enthusiast; but Van Helmont, though of the same sect, appears to have been a man of good judgment and acute observation. In pursuit of their fancies, they discovered many chemical changes produced by the mixture of bodies; and, among other sciences, medicine received considerable improvement from their misdirected labours.

**A'LCHERON, LA'PIS**, (so called from the Arabic term *ALCHERAN*, a horn; because it was found of a horny consistence). The stone in the gall-bladder of a bull, or ox, called *bezoar bovinus*.

**A'LC'HIBRIC.** **A'LC'HIBERT.** See **ALKIBRIC**.

**ALCHIM'LLA**, (so called, because it was celebrated by the alchemists); called also *branca*, and *pes-leonis*; *stellaria*; **LADY'S MANTLE**, and **LION'S FOOT**. **Rulandus** calls it *diaphencia*.

The leaves are gently astringent, the root is of the same quality; but this plant is not in any repute as a medicine.

**ALCHIM'LLA SUPINA GRAMIN FOL.** See **KNAWE**.

**A'LC'HITRON**, **OIL OF JUNIPER**; see **JUNIPERUS**. Also the name of a dentifrice of Messuc.

**ALCHO'LEA**, (Indian term). A sort of animal food made of beef or other flesh, pickled and dried, then boiled and potted for keeping. It is used by the western Moors. See **Philos. Trans.**

**A'LC'HUTE.** See **MORUM**.

**A'LC'HYMY.** A composition of copper, with a small quantity of arsenic, resembling silver.

**ALCIBIA'DION**, so called because Alcibiades first used it against the bite of a serpent. See **ANCHUSA**.

**A'LCIMAD.** See **ANTIMONIUM**.

**A'LCOB.** See **AMMONIAC. SAL.**

**ALCO'CALUM.** See **CINARA**.

**A'LCOFOL.** See **ANTIMONIUM**.

**A'LCOHOL, or A'LC'HAHOL**; **A'LC-KA-HOL**. It is an Arabian word, signifying an impalpable powder, which the Eastern women used to tinge the hair and the edges of their eye-lids. As this powder, viz. an ore of lead, was impalpable, the same name was given to other subtile powders, and to spirit of wine exalted to its highest purity and perfection. See **VINUM ADUSTUM**.

**A'LCOHOL MA'RTIS.** It is the filings of iron rusted by adding urine to them. When the whole is per-

fectly rusted, pure spring water is repeatedly added, until all that is urinous is washed away, and the remaining powder is the *alcohol martis*. Musgrave employed it with the theriaca in misplaced gout, to bring it to the joints.

A'LCOL, (ALCAL, Arab.). See ACETUM.

ALCOLA, (ALCALA, *filth*, Heb.). APHTHA, which see. Paracelsus gives this appellation to the tartar or excrement of urine, whether it appears as sand, or mucilage.

ALCOHOLIZATION. The rectification of alcohol; and, according to Starkey, the union of alcohol with fixed alkalis, which forms a neutral, and the alkali is volatilised.

ALCOLI'TA. See URINA.

ALCOLISMUS, (from *alcohol*). Reducing any thing to powder by corrosion.

ALCO'NE. See ÆSECAVUM.

A'LCOR. See Æs USTUM.

AL'CTE. It is the name of a plant mentioned by Hippocrates; Foesius thinks it is the Elder. See ACTE.

ALCU'BRITH. See SULPHUR.

ALCYON FLUVIA'TILIS. See ALCEDO.

ALCYO'NIUM. BASTARD SPONGE. It is the froth of the sea hardened by the sun, of different shapes and colours. It is so named, from the bird ALCYON, which builds on the sea, and whose nest it is said to resemble. It is difficult to say what the Greeks called by this name. Dioscorides names five sorts; viz.

1. ALCYO'NIUM DU'RUM. HARD BASTARD SPONGE.

2. FARRA'GO; called also *farrago australis*, *alcyonium*, *vessicaria marina nigra*.

3. ALCYO'NIUM VERMICULA'TUM, or VERMICULA'TE. VERMICULATE BASTARD SPONGE.

4. ALCYO'NIUM SUPPOSUM. Lemery calls this *alcyonium molle*. TREADY BASTARD SPONGE.

5. ALCYO'NIUM TUBERO'SUM. Lemery calls this *alcyonium foraminosum*. TUBEROSE BASTARD SPONGE.

There are many other species; they are calcined with a little salt as dentrifices, and are used to remove spots on the skin.

ALDABA'RAM. See ALBADA'RA.

ALDIN, ET ALDIN. HORT. FARN, i. c. Exact. Descriptio rariorum quarandum Plantarum Horti Farnesiani Tobie Aldini. Rome, 1625, fol.

ALDROV. EXANG. i. c. *Aldrovandus* De Animalibus exangibus, Bonon. 1642.

ALE, (*oel*, Dan.; *aile*, Fr.; from *alo*, to nourish). The ancient Saxons called it *acl*. The Germans first invented and brought it into use.

Ale is distinguished from BEER, by being fresh or new, while beer is kept until the remaining saccharine matter is more completely changed to a vinous spirit by a slow fermentation.

Beer, called by the Latins, CEREVISIA, from Ceres, because corn is its principal ingredient; also LIQUOR

CERERIS; VINUM HORDEACEUM, *barley-wine*; VINUM REGIONUM SEPTENTRIONALIUM; sometimes *bira*.

Ale produces colics, and is occasionally, when not well fermented, acescent; but does not produce calcareous diseases, as has been asserted. Those who drink ale are stronger than those who drink wine; and those who do not drink strong liquors are said not to be able to labour so well as those who do; but this does not appear to be invariably true. Ale-drinkers are fat, occasionally gouty, but, on the whole, healthy. Cordials may fit the person for extraordinary exertions, but should not be commonly used. Ale, however, must not be considered as one of these. When well fermented it is an wholesome beverage, and seems only to disagree with those subject to asthma, or any disorder of the respiratory or occasionally the digestive organs. See DRINKS, BEER, PORTER.

If malt liquor, of any degree of strength, is become flat and acid, as it is used, it should be drawn out of the cask into a jug, in which as many drams of powdered chalk should be put as pints of liquor; thus an effervescence will be raised, a sprightly, though not very agreeable, taste will be restored to the liquor, and its acidity will be destroyed.

Ale being in some countries cheaper than wine, hath occasioned it to be medicated for the same purposes; and there are two ways of impregnating malt liquors with medicinal substances; *first*, by macerating the ingredients in the ale after it is duly fermented; *secondly*, by adding them to the liquor while it is fermenting, that by the power of fermentation the medicinal virtues may more fully be extracted; of nutmeg, for instance, one dram powdered will flavour a large vat of fermenting ale, but when the fermentation ceases, it flavours but a very small quantity. Branches of the spruce fir, fermented with beer, render it wholesome, antiscorbutic, and useful in cutaneous diseases. It is the pleasantest form of turpentine; and many who have begun it as a medicine, have continued it as a luxury.

The following is an agreeable bitter, and far preferable to any of the purls.

CEREVI'SIA AMA'RA. BITTER STOMACH-IC ALE.

R. Rad. gent. cort. limon. rec. āā ʒiv. piper. long. ʒi. cerevis. Cong. i. infund. sine calore.

CEREVI'SIA ANTISCORBU'TICA. ANTISCORBUTIC ALE.

R. Fol. cochl. hort. rec. m. viij. ras. guaiac. ʒj. sem. coriand. ʒij. fol. senn. ʒss. infund. in cerevis. recent. durant. fermentat. Of these medicated ales ʒss. may be taken night and morning.

Various other impregnations of ale have been used as diet drinks or medicines. We find in the old dispensaries, ale against the gout; for the eyes; for the head, &c. Vulgar practice still retains an infusion in ale of some virtue; viz. of the *broom ashes*, which contain an alkali, with the diuretic oil of the broom. Syrup of ale consists of the ale inspissated before it is attenuated by fermentation, and is little more than a mucilaginous infusion of malt, employed as a demulcent, in the diseases for which this class of medicines is used. Gill ale is an infusion of ground ivy, and supposed to heal internal wounds, and to relieve diseases of the breast. Dr. Butler's purging ale is indeed purgative, from containing senna; but has numerous other ingredients, which tend to no one purpose unless it be slight-

ly expectorant. *Ale berry* is a sudorific, and consists of ale boiled with bread and mace.

ALE'CARITH. See ARGENTUM VIVUM.

ALEFA'NTES; i. e. FLOS SALIS. FLOWER OF SALT.

ALE'IMMA, (from αλειωω, to anoint). A greasy ointment, or a liniment, without wax, to give it a consistence.

ALE'ION. Hippocrates uses this word as an epithet for water.

ALE'IPHA, (αλειωω, to anoint). Any medicated oil, impregnated chiefly with the juices of vegetables.

ALE'LAION, (from ἅλς, salt, and ἔλαιον, oleum). It is oil beat up with salt to apply to tumours. Galen frequently used it.

ALE'MBACI. BURNT LEAD.

ALE'MBIC. See ARGENTUM VIVUM.

ALE'MBICUS. Avicenna considers this as an Arabic term; but others suppose it half Arabic and half Greek, from the Arabic particle *al*, and αμβιξ, which is again derived from αμβαινω, for ἀναβαινω, to ascend. Seneca calls it in the Latin language *miliarium*. Alembic and Moor's-head. It is also named *capella*, *capitulum*; it is a copper cap of a still tinned in the inside, made like a head, in which the pipe passing through a tub of cold water, is fixed to receive the vapour from the heated cucurbit or body, to convey it to the receiver. Before retorts were used so commonly, the matter distilled was put into a vessel called a body, with a head placed on it to receive the vapour, whence it was conveyed by a canal, called the rostrum, or beak, to the receiver; this head is properly the *alembic*, and is called *alembicus rostratus*, i. e. the *beaked alembic*, to distinguish it from *alembicus cæcus*, or *blind alembic*, which is without a canal, as it is to receive dry substances that are sublimed, into it. The body of the *alembic* was placed over a fire in hot pump-water, hot salt-water, or hot sand. *Alembics* are preferable to stills, by requiring less fuel, and not so readily imparting empyreuma. In quickness, and the attention necessary to regulate the heat, they are less convenient.

ALE'MBROTH. A Chaldee word, importing the Key of Art; some explain it by sal mercurii, or sal philosophorum et artis: others say it is named *elem-brot* et *sal fusionis*, or *sal fixationis*. *Alembroth desiccatum* is said to be the sal tartari; hence this word seems to signify alkaline salt, which opens the bodies of metals by destroying their sulphurs, and promoting their separation from the ores. From analogy, it is supposed to have the same effect in conquering obstructions and attenuating viscid fluids in the human body. A peculiar earth, probably containing a fixed alkali, found in the island of Cyprus, has also this appellation; and a solution of the corrosive sublimate, to which the muriat of ammonia has been added, that greatly assists the solubility of the mercurial salt, is called *sal alembroth*.

ALE'MZADAR.}

ALE'MZADAD.}

See AMMON. SAL.

ALEOPHANGI'NÆ PILULÆ; these are the pil. aromaticæ of Messue. Joined with the hellebore they have been called pil. aleophang. capitales et stomachicæ.

A'LEOS, (from αλεω, heat). Taken as an adjective it signifies *heaped, crowded, condensed, continued*; as a substantive, *heat* or *warmth*.

ALEPE'NSIS. See MANNA.

A'LES, (from ἅλς, salt). The name of a compound salt.

A'LESCH. See ALUMEN PLUMOSUM, N° 2.

ALEU'RON, MEAL, (from αλεω, to grind). Strictly it is the meal of wheat, though commonly applied to other sorts. See ALPHITA.

ALEXA'NDRIA. See LAURUS ALEXANDRINA.

ALEXA'NDRI ANTIDOTUS AU'REA. ALEXANDER'S GOLDEN ANTIDOTE. Myrepsus gives us the prescription; it is composed of animal, vegetable, and mineral substances, and contains about seventy ingredients.

ALEXA'NDRI REGIS COLLYRIUM SICCCUM. King Alexander's dry medicine for the eyes. It was made of saffron, Celtic nard, and canal coal.

ALEXANDRI'NA. See LAURUS ALEXANDRINA.

ALEXANDRIUM EMPL. VIRIDE. A plaster described by Celsus, made with wax, plumose alum, &c.

ALEXA'NTHUS. See ERIS FLOS.

ALEXICA'CA, (from αλεξω, to drive away, and κακον, evil). See ANTIDOTUS and AMULETA.

ALEXIPHA'RMICA. ALEXIPHARMICS, (from αλεξω, to repel, or drive away, and φαρμακον, poison,) called also *antipharmica*, and *caco alexeteria*. Medicines to preserve the body against the power of poisons, or to correct or expel those taken into the machine; the words ALEXETERIA, THERIACA, and ANTIDOTA, have the same import; hence warm stimulants and diaphoretics may be considered of this class; and perhaps the whole power of the alexipharmics will be chiefly of service by acting in one of these modes. Their celebrity among the ancients arose from the frequent apprehensions of poison; and, in the middle ages, the nature of the apprehended poison only was altered, and the preventive was employed against contagious fevers. The term has been also applied to Amulets. See AMULETA.

ALEXIPYRETICUM, ALEXIPYRETOS, or ALEXIPYRETUM, (from αλεξω, to drive away, and πυρετος, a fever). A remedy for a fever, or πυρ, fire.

ALEXITE'RIA, ALEXITERIALS, (from αλεξω, and τρεω, a preservative from contagion). Hippocrates used the word *alexiteria* to express help or remedies. Strictly speaking, alexiterials were opposed to poisons inflicted from causes external to the body. See ALEXIPHARMICA.

A'QUA LA'CTIS ALEXITE'RIA. *Alexiterial milk-water*.

AQ. ALEXITE'RIA SPIRITUOSA; called also *epidemica aqua*, plague-water. Each is now rejected from modern pharmacopœias.

ALFA'CTA. See DISTILLATIO.

ALFA'DIDAM. The scoria of gold, iron, or copper; also burnt copper. See Æs USTUM.

ALFA'TIDA, burnt copper, or the scales flying off from copper. See Æs USTUM.

ALFA'TIDE. See AMMONIACUS SAL.

ALFA'SARA, or ALPHESARA. Arabic terms for the vine. The name of a confect described by Messue; from the Arabic particle *al*, and *fesera*, or *phiser*, the root of the vitis alba.

A'LFIDAS. See PLUMBUM.

A'LFOL. See AMMONIACUS SAL.

A'LFUSA. TUTTY. See TUTIA.

ALGA. A weed growing upon the sea shore, and in cold situations; called also *ulva*, *fucus marinus*, *bryon*

*thalassium*, GRASS-WRACK, WRAKE, SEA-WEED OR GRASS, and SEA-MOSS.

There are three kinds distinguished by La Marck: the first, filamentous, gelatinous, and membranous; the second, with more decided appearances of fructification; the third, with those parts more obvious, and opening to scatter the farina or deposit seeds. Some of the species are employed in the manufacture of kelp on the coast of Scotland; but in medicine their powers are, perhaps, principally owing to the sea salt they contain, and little choice is necessary. The bladder oar-weed, *fucus vesiculosus*, has been preferred, but with little reason. On the coast of the Mediterranean sea a species of *alga* is gathered and dried to feed oxen.

The seeds of the *alga* are more perfect than those of the fuci, for its vessels gape when perfect, and the seeds fall out. Stackhouse *Nereis Britannica*, Major Vellei on Marine Plants; Turner on Fuci, Linnean Transactions, vol. iii.

ALGA MARI'NA LATIFO'LIA VULGATISSIMA, the COMMON SEA-WRACK, see KALI.

A'LGAË, (from *alga*, sea-weed). It is a term botanically applied to a tribe of plants which have their roots, leaves, and caudex, in one, and comprehends sea-weeds, and some other aquatic plants.

A'LGALI. See NITRUM.

A'LGALY, (ELGALA, hollow, Arab). AN HOLLOW LEADEN PROBE, OR CATHETER. See CATHETER, and SOUND.

A'LGAMET. COALS.

A'LGARAB. See ÆGYLOPS.

A'LGAROT, ALGAROTHI, ALGEROTH, (PULVIS). So called from VICTORIUS ALGAROTH, a physician of Verona, and its inventor. It is the same with the *mercurius vitæ*; and is only the antimonial part of the butter of antimony, separated from some of its acid by washing it in water. It is tasteless, but violently emetic, in doses of two or three grains; and is prepared with antimony and sublimate, or by mixing water with the butter of antimony, which precipitates a white powder, &c. This is the preparation preferred by many chemists for making the emetic tartar.

ALGA'IA. CIVET. See ZIBETHUM.

ALGE'DO, (αλγος, pain). SUPPRESSED GONORRHEA; when it has stopped, or been checked suddenly after it has appeared, and is attended with pain.

When it thus stops, a pain is continued to the bladder by the urethra; to the anus by the acceleratory muscles of the penis; and to the testicles by the vasa deferentia, and vesiculæ seminales. These last do not always swell, but the urine is partially suppressed.

In this case, calomel repeated, so as to purge, often brings back the running, and then all difficulty from this symptom ceases. If the pain is great, and a sanguinary plethora requires it, after bleeding, may be given of calomel prepared ten grains, opium one grain, made into a bolus with conserve of roses. This should be taken at night, and followed in the morning by the infusion of senna with tamarinds.

In these and other disagreeable symptoms, such as ophthalmies, deafness, swelled testicles, &c. from the suppression of the virulent gonorrhœa, where the common methods fail of reproducing the discharge, it has been recommended to introduce a bougie into the urethra, smeared with the virus of an infected patient:

Dr. Swediaur says, "The method proposed has been tried many years ago in one of the first military hospitals in Europe, with constant success, and has since been confirmed by Dr. Lange, in his Treatise on Ophthalmia. See his Practical Observations on Venereal Complaints, p. 53.

ALGE'MA, or ALGEMATO'DES, (from αλγεα, to be in pain). UNEASINESS, PAIN. Hippocrates often uses the word αλγυμα, to signify the disease whence the pain proceeds. James's Med. Dict. See DOLOR.

ALGERIÆ, or ALGERIE. LIME. See CALX.

A'LGIDA, (from *algeo*, to be cold). Numbed, withered, chilled.

A'LGOR, (from the same). A sudden chillness affecting the body, or any detached portion of it.

A'LGOSAREL. The Arabian term for the *daucus sylvestris*.

ALHAGI, (Arab.). The plant thorny SYRIAN BROOM; called also *agul et almagi Arabibus genista*, *Spartium spinosum*, *spinosum Syriacum*. *Hedysarum alhagi* Lin. Sp. Pl. 1051.

It is commonly met with in Persia and Mesopotamia, where the inhabitants gather from it a sort of manna, in grains about the size of coriander seeds. The Arabians call this *manna, tereniabin, or trangebin*. Raii. Hist. The leaves of the alhagi are hot and pungent, the flowers purgative.

There is another species called *alhagi maurorum*.

ALHA'NDALA, (ALHANDAL, Arab.). An Arabian name for the colocynth. See COLOCYNTHIS.

TROCH. ALHANDAL. The troches of *alhandal* is a composition as old as Messue, but is now not used.

ALHA'NNA. See ALANA TERRA.

ALHASEF, (ALASAF, filth, Arab). A sort of pustule, called HYDROA.

A'LIA SQUILLA, (from αλιος, belonging to the sea, and σκίλλα, a shrimp). The PRAWN.

A'LICA, (from *alo*, to nourish). A sort of food admired by the ancients; it is difficult to say whether it is a grain or preparation from some seed: many writers speak of it as a sort of wheat; but upon the whole it seems to be a kind of meal made into frumenty, to be eaten with milk, &c. Salmasius says, that *alica* is one sort of the chondros of the Greeks, which was grain broken into large fragments, or rather only freed from the husks, but not ground in a mill; called also *apharema, adroteron, farinarium*.

A'LICES, (from αλιζω, to sprinkle). Little red spots in the skin, which precede the eruption of pustules in the small-pox.

ALICO'RNÜ, (from the Hebrew terms *ali*, lifted up, and *karan*, a horn). See UNICORNÜ.

ALIENATIO ME'NTIS, (from *alieno*, to estrange). See DELIRIUM.

ALIENUM, (from the same). In a medical sense it is any thing foreign and troublesome to the body. Sometimes it means corrupted.

ALIFO'RMIS, PROCESSUS. See PTERYGOIDES PROCESSUS. (From *ala*, a wing, and *forma*, the shape).

ALIFO'RMIS MUSCULI. See PTERYGOIDEI.

AL GULUS. See CONFECTIO.

A'LILAT, or αλιτλα, an Arabian name for *Lucina*, or the goddess which the Greeks supposed to preside over child-birth.

A'LIMA, (from αλιμος, belonging to the sea). A

sort of sand from which lead and other metals are obtained.

**ALIMENTA, ALIMENT;** OR FOOD BOTH SOLID AND LIQUID: (from *alo*, to nourish). It is such matter as is convertible by the actions of the body into an alkaliescent gluten, of which all our solids and fluids are formed, and by which their waste is repaired. Next to air, food is the most necessary thing for the preservation of our bodies; and as, on its choice, our health greatly depends, it is of importance to understand, in general, the properties of our aliments, so as to judge not only the kind of food proper in different situations to support life, but to restore health when impaired; and, in particular deviations from health, what is the best adapted to restore us.

Our blood and juices naturally incline to a putrid acrimonious quality: fresh chyle, duly received, prevents this destructive tendency, and preserves in them that mild albuminous state that is alone consistent with health.

The subject of aliment, if pursued at length, would require a volume. It must be considered here more shortly; but we shall offer an outline, which may be easily filled up. The structure of the human stomach shews that man was not intended to be granivorous, or exclusively herbivorous; the length of the intestines, on the other hand, proves that he was not wholly designed to be carnivorous. In all situations where the dictates of nature have been complied with, mankind have consequently mixed both foods, and the proportions have been such as fancy or necessity may have suggested; so accomodating is the animal economy, that it adapts itself to every kind of diet, and the axiom is universally true, *sanis omnia sana*.

It will be at once obvious, that the food, taken in, is by no means in the state which nature requires to form our mass of blood. It must undergo some change; a process which, in its successive stages, is called **DIGESTION AND ASSIMILATION**, q. v. These subjects we must not anticipate; but may now remark, that aliment is only admitted into the system in the form of a bland oily fluid, named chyle. This, though resembling milk, yet essentially differs from it, since milk is not absorbed until it has been coagulated and experienced some chemical changes. The great divisions of our aliments are vegetable and animal: these, as usual, are in their confines scarcely distinguishable, and the mushroom of the vegetable kingdom is of a more animalised nature than even the milk of the most carnivorous animal, the dog. Of vegetable substances, the prevailing principle is carbon; of animal, azote. The changes which the first undergo are, therefore, the most considerable, and their assimilation requires the longest time. We have already observed, that *difficult* and *slow* of digestion are not synonymous; and this is particularly exemplified in the digestion of vegetable substances, which excite little commotion in the system, though they are long retained in the primæ viæ; and the criterion we shall employ of *difficult* digestion, will be the *exacerbation of hectic paroxysms*. In hectic, the arterial system is peculiarly irritable, and the slightest exertion of the digestive organs accelerates the circulation.

The nutritious parts of the vegetable kingdom are mucilage, starch, or sugar. In the lowest degree of nutriment are the **ESCULENT PLANTS**, such as the bete, the spinach, and the lamb's lettuce. The cabbage and wa-

ter-cresses, scarcely ranking higher in nutritious powers, have some effect from their peculiar acrimony. Among the vegetables of weak nutritious powers must be reckoned the marine algæ, which, perhaps, except in one instance, owe their chief advantages to the stimulus of the salt. The *fucus esculentus palmatus* and *digitatus* are used; the second is the dulse of Scotland. The *ulva umbilicalis* affords the laver, and the *u. latissima* (Iceland sea-grass) is saccharine. The Iceland liverwort, lichen *Islandicus*, we shall speak of as a medicine. The *siliquosæ* of Linnæus follow, including the endive, the lettuce, the celery, the artichoke, and asparagus. Many of these are highly acrimonious, but deprived of their peculiar principle by confinement from light, styled etiolation, or bleaching. The early buds of the asparagus are only employed, in which the peculiar acrimony is not unfolded.

We should next arrange the roots: of these the radish and the turnip are the least nutritious, and the *umbiliferæ* of Linnæus follow: they include the carrot, the parsnip, and the skirret (*sesarum*). The *semiflosculosæ* are more nourishing; the orchis, which produces the salep and the potatoe, with some others, are of this class: those which rank with them, the onion, the leek, the garlic, including its species, the chalot and rocambole, are not, *with us*, employed as aliments, but must rather be considered in the rank of condiments. The leguminous seeds, chiefly of the *papilionaceæ* of Linnæus, are next in order: they unite with the herbaceous matter a large proportion of mucilage; we shall enumerate them in the order of their nutritious powers, viz. kidney-beans, pease, beans, lentils, and cicer seeds (*cicer arietinum*, Lin.) As nutrients, the gums have also held a place. We know not their comparative value; but shall not be greatly in an error if we add here the only substance of this kind, of which there has been any trial, viz. the gum arabic, the production of a species of mimosa. This, from the testimony of Hasselquist, has been found nutritious; and of a similar quality, perhaps, the gum tragacanth and the cherry-tree gum may be found.

In this climate some of the fruits are less nourishing than a few of the roots we have mentioned; but in warmer climates they are more so, and it was at least improper to separate them. The *cucurbitaceæ* of Linnæus, including cucumbers, melons, pumpkins, &c. are in the lowest rank: they are followed by the *senticosæ*, in which class currants, strawberries, raspberries, gooseberries, and grapes, are arranged: the *hesperideæ* (oranges), *pomaceæ* (apples and pears), *drupaceæ* (apricots, peaches, plums, and cherries), follow, with little distinction, but nearly in the order assigned. The dry fruits of warmer climates, raisins, dates, and figs, are more nourishing.

We next arrive at the **SEEDS**, which are nutritious, from their amylaceous principle, viz. the *cerealia*. Of these we may mention rice, wheat, barley, oats, rye, Indian corn, millet, buck wheat, Guinea corn or sergo (*holchussorgum*, Lin.), flote fescue grass (manna seeds), and the lotus of Africa, mentioned by Park. The **FARINACEOUS** roots of warm climates are more nourishing, viz. the sweet potato, the Jerusalem artichoke; the various yams, viz. *dioscorea sativa*, tryphilla, and bulbifera, the toyos and black cocao (*arum colocasia* and *sagittifolium*), the farina of the sweet and of the bitter

cassada (*Iatropa manitot* and *ianipha*), and the starch of the arrow root (*maranta arundinacea*). The farina of the sweet cassada is the tapioca. We have placed the cerealina nearly in the order of their nutritious powers, for perfect accuracy is unnecessary; but we must now add, what is of more importance in a dietetic view, the order in which their saccharine principle is most readily evolved, and, of course, that in which they appear most acescent, viz. oats, barley, wheat, millet seed, rye, Indian corn, and buck wheat: the order of the others has not been ascertained.

After the arrow root we must mention the farinaceous fruits, and the farinaceous medulla: we know not that as nourishment they merit any distinction. Of the former kind we find the bread-fruit tree of the South-Sea islands (*artocarpus incisa* Lin.), the bread nut (*Brosimum alicastrum* Lin.), the sweet chesnut, the plantain tree and banana fruit (*Musa paradisiaca* & *sapientum* Lin.): of the latter the sago, the medulla of the *sagus farinifera* of Gärtner; the cabbage-tree palm (*areca oleracea*), and the meal bark (*cycas coffra* Lin.).

When with the farina a mixture of oil is discovered, the nutritious powers are more conspicuous; but the oil is sometimes so closely involved with the farina, as in the almond, the cashew nut, the filbert and walnut, that the stomach, except in its strongest state, is unable to separate it; while in the chocolate nut (*Theobroma cacao*), the cacao nut (*Cocos nucifera*), and particularly in the butter cacao nut (*Cocos butyracea*), it is so loosely combined as often to produce inconvenience. We must not, however, confound the butter cacao nut with the butter-nut oil described by Mungo Park; though, when expressed, it is the *oleum calajphi*, the cow-nut butter. The tree noticed by Park is probably a species of the *bassia* Lin. The fat oils, viz. the oils combined with mucilage, may be still more nutritious, but they are not very digestible, and our experience with them is consequently limited.

THE SACCHARINE SUBSTANCES as nutriments are highly estimated, and perhaps their power is increased when joined with farina. We thus, therefore, place in the first rank, as least nutritious, refined sugar; it may be followed by coarser sugar, honey, maple sugar, beet-root sugar, and sugar of malt.

In this variety of vegetable bodies we must fix our eyes on the leading constituent parts. These, in a chemical view, we shall find to be mucilage and sugar, for starch differs only from mucilage, in containing a less proportion of caloric. Mucilage contains oxygen, hydrogen, carbone, and azote; sugar no azote, and a larger proportion of oxygen. We are yet too little acquainted with the influence of the chemical principles on the process of digestion, to be enabled to say how far one or the other of these principles may render a substance eligible as a nutrient from an examination of its analysis. We can perceive that oxygen is a necessary part of our system, as it gives a more brilliant hue to the red blood, and as our most recrementitious fluids are azotic. On the other hand, azote is necessary to animalise the vegetable portion of our food, and then becomes injurious. We can go no further in this path. From experience we find the herbaceous substances cold in the stomach, and affording so little support as to render the constitution unfit for great exertions, without at least some condiment, if not stronger nutriment. The cerealina give a better support, for reasons that we shall soon

perceive: the farinaceous roots still more; but these also require assistance for their more perfect digestion: the oils and sugars, as we learn from Dr. Stark's experiments, will support the body for a time in tolerable health. The Irishman lives on potatoes, but he adds the stimulus of whiskey; the Spaniard and the Frenchman on bread, but with the assistance of olives and garlic. The infusion of oat-meal in Scotland, or the oat-cakes, require the warmth and animal impregnations of milk, if not of malt spirit; and the moss of Iceland would be an insalubrious food without the dried fish.

Yet in corn, in potatoes, in parsnips, and numerous other vegetable substances, particularly the grains, a principle, resembling that in animals, is found. It is styled the gluten, and resides in the skin of corn, and is more intimately mixed in the potato. In fact, the root of the latter consists of follicles containing farina, and the coats of these seem to contain gluten. The prevailing principle of gluten is azote, and, in each experiment, its chemical nature is animal. MUSHROOMS, which unite in a chemical and a dietetic view the vegetable and animal kingdoms, abound in gluten, and produce, on distillation, ammonia. We have, however, no experience of these as an article of diet; they are seldom employed but as a condiment. The various kinds used are the common mushroom (*agaricus campestris* Lin.), truffle (*lycoferdon tuber* Lin.), orange agaric (*agaricus deliciosus* Lin.), coral clavaria (*cl. coraloides*), the *agricus mucheron*, and the *phallus mitra* Lin.

We approach still nearer the animal kingdom in the various MILKS. These consist of an animal oil; of a coagulable part, which is gluten; and sugar. Milk, on standing, absorbs oxygen, which promotes the separation of cream, and suffers an halitus to escape, which has not been examined, but which is certainly not an aqueous fluid only. The cream, with the oil, contains some gluten and sugar, and the latter are left in the butter-milk, after the operation of churning. This subject will be detailed more at length under the article MILK: the outline was only necessary to explain the dietetic properties of different milks. In diet, the milk of ruminant animals is chiefly employed, viz. cows', goats', and ewes' milk: this is the order of the nutritious properties, beginning, as usual, with the least nourishing. Cows' milk contains also the least, and ewes' milk the largest, proportion of cheese. Of the non-ruminant animals we employ women's milk, asses', and mares': they nearly resemble each other; but women's milk is the lightest, and perhaps contains most sugar. Later experiments seem to have shewn that it does not coagulate with vegetable acids. The coagulable part of milk, with more or less of the oil pressed into the form of cheese, will be afterwards considered.

THE ANIMAL FOOD which digests in the stomach with the least irritation, though not the most quickly, is the white meat of all animals, and the meat of the younger ones. White and young meats abound in jelly, which forms also a considerable proportion of the membranes, tendons, and cartilages. Jelly, though soluble in water, is not affected by alcohol; and, while it resembles albumen, yet differs greatly from it. Jelly contains a larger proportion of earth than albumen, and the further an animal is advanced in life, so much more are its fluids loaded with earth. Jelly also contains an alkaline phlegm of an animal nature which readily putrifies, with a

larger proportion of carbone, the predominant principle of vegetable substances. To these it adds hydrogen and azote; the last of which abounds more in the coagulable lymph of the blood, and still more in the fibrin. See BLOOD.

Birds have been considered as of more easy digestion than mammalia. This however is not unexceptionably true. Even in the gallinaceous tribe there are some exceptions; but it may be admitted in general, that the young of the feathered race are easily digestible. The parts of the bird most so are those most used; as the wings of the wilder kind, and the legs of the tame ones. Birds also differ in their digestibility, as they are more or less alkaliescent, or more or less oily. Alkaliescence is a term introduced into diætetics, on a principle neither correct in a chemical nor a physiological view; yet it may be admitted as a naturalised foreigner, without examining its pretensions. Wild animals are styled alkaliescent; as woodcocks, snipes, moor-fowl, &c. among birds; hares, red-deer, &c. among the mammalia. These are perhaps justly considered as more easily and quickly digestible than the tamer animals of a similar kind: when they have been some time pursued, they become aliments still more easily assimilated. It is said, we know not with what truth, that bulls baited become wholesome food; and that an act of parliament exists, which directs, that no bull should be killed without being thus previously irritated and tormented.

On the other hand, the oily birds, the anseres for instance, are gross and indigestible, though only when full grown. We dare not say, that in earlier periods they are very easily subdued by the stomach, though, on the whole, they are then a mild, and generally harmless, nutriment.

QUADRUPEDS differ in their digestibility from various circumstances. In general, the *pecora* afford mild nutriment, though food is taken from the other orders also; but the particular animals we shall afterwards separately enumerate. The size of the animal, independent of its age, appears of consequence, as of the larger animals the fibres are coarse and more indigestible. The mode of life, and the exercise, are of importance in this view. An animal living according to its own nature is a more nourishing, though not always a more delicious food, than one crammed or pampered. A grass lamb is more digestible and nourishing than house lamb; a black turkey, that roosts on trees and feeds on chesnuts and acorns, superior to that fattened in the coop. The ground on which they feed, the food they eat, and the air they breathe, necessarily alter their nutritious, and consequently their digestible, powers. We know the fatal disease, the rot in sheep, which arises from the air, probably from hydrogenous gas, since sheep will catch the infection in a single night; and we can easily conceive, that, in a slighter degree, the same disease, though less obvious, may injure their nutritious powers. Sheep, fed on turnips, are less nutritious than those which have grazed on the finer turf of more elevated districts. The cow, fed on oil-cakes, gives an ill-tasted milk, while its flesh is coarse and indigestible.

A circumstance influencing the digestibility of animal food, not generally noticed, is what the graziers call the proving state. When an animal is improving in condition, the meat is tender and easily digestible:

when its condition is growing worse, though equally fat, and in appearance promising, it is tough and not easily assimilated. This peculiarity proceeds further; and, in proportion to the rapidity of the improvement, the meat is preferable in flavour and solubility. Thus an ox, worked to the lowest degree of emaciation, affords, when quickly fattened, the best beef. This, we have said, is independent of the fatness. Fat meat, however, is more nourishing, though in weak stomachs not so easily digestible. Savages are fond only of the fattest meats, and they style lean cattle bread meat: we have heard a similar expression among the rustics in our own remote provinces, so universal is the opinion derived from experience. The marrow of meat, though resembling the fat, is not equally difficult of digestion: by some authors it is arranged, we suspect with reason, among the most digestible substances.

Another circumstance which influences the solubility of meats is castration. The flesh of the ox is more digestible than that of the bull; of the wether than of the ram; of the capon and the pullard rather than the cock or the hen. In reality the meat approaches that of the female, though more firm, and probably of a higher flavour. If to this there is any exception, it is in the capon, whose flesh is more moist and soluble than that of the hen. The preservation makes some difference in this respect. Animal food, kept till putrefaction *approaches*, is more soluble than at an earlier period. We have said "approaches," for, when in the slightest degree arrived, it generally excites nausea, unless the stomach be stimulated, and the further progress of putrefaction prevented by the warmest condiments. Meat preserved by freezing, and gradually thawed, is in the state of that well kept. By salt and smoke it is hardened, and rendered more indigestible; by sugar we think it is preserved in nearly as soluble a state as by cold. The mode of cookery also affects the solubility of animal food. Boiling renders it more digestible than roasting; and this than baking or frying. Various fancies have prevailed on this subject, and different modes have been recommended according to the inclinations of different authors; for physicians usually advise what they themselves like. In general, however, in roasting, baking, and frying, the oily parts are rendered empyreumatic; and a substance of this kind is very indigestible. If, of roasted meat, the inside parts are only taken, the difference is not considerable; but in baking and frying, the gravy is retained, and a change similar to the empyreuma of oily substances takes place. This is known from the preference given to the superior flavour of meat, dressed in these manners.

The AMPHIBIA form a link between animal substances and fish. The turtle, the delight of the epicure, is an example of this class; but the species we shall afterwards mention at length. The conger eel, in its flesh, approaches also animal substances.

The rank which fish in general ought to bear in the scale of digestibility, has not yet been settled. Sea-fish bear, we suspect, the same relation to river-fish, that wild animals do to tame ones; and the fish of stagnant ponds are less digestible than those of running water. The meat of the same fish differs according to the period of spawning: fish are in perfection not at the moment of this crisis, but when the melt or pea begins to enlarge. They differ also according to the

time they have been killed, and from the operation of crimping. These subjects must be resumed when we speak of the different kinds of fish, as it would not be easy to give a general rule.

Of the insects but one species (the locust) has been eaten, except those of the sea. Of the locust we have no experience; but the white kind, not unlike crabs, is seemingly a mild nourishing food. In the east they are boiled or roasted, and, like crabs, become then of a red colour. They were eaten, as we are informed by Diodorus, by the Æthiopians: and Dampier tells us, that the custom still continues. Of the sea insects, crabs, lobsters, &c. appear to be mildly nutritious; in many constitutions more so than animal food.

Of the terrestrial VERMES we take but one species, the snail, and this in England rather as a medicine than as food. The marine vermes, the oyster, &c. rank among foods easily digestible, and may be considered, *when not roasted*, as the most digestible of animal nutriment.

We cannot leave these more general doctrines respecting aliment without noticing some fancies respecting the nutritious powers of mineral substances. The pangolin has undoubtedly been dug out of a sand hill, where it seemingly could have no access to vegetable or animal nutriment: yet we know not but that it might have laid in a stock of food, as some animals that have their returning periods of torpor require no nourishment for a long period: nor can we say that it finds no vermes in the sand. Some tribes of Indians have also, it is said, in periods of scarcity, devoured a species of steatite. That the greasy appearance of some steatites may have induced them to consider such mineral substances as nutritious, is not surprising; but that they have proved so is doubtful. Much of the pain of hunger arises from emptiness, and this may be in part avoided by any substance; and it is equally avoided by external pressure on the stomach, a practice not uncommon among savages, when food cannot be procured.

As we have now stated the more general facts respecting aliment, we shall resume the consideration of the different classes, not only to point out the different species employed, but to remark some peculiarities which will influence our conclusions in the choice of different articles of food.

We began with the BIRDS, as many of these afford lighter nutriment than the flesh of quadrupeds. We shall follow in some measure the classes and orders of the historian of nature, though we must invert their order. Birds, in a dietetic view, may be divided into the more or less digestible. The extremes are well marked, *viz.* the gallinæ and the accipitres of Linnæus. Experience has decided that chicken are the most easily assimilated of the feathered race; and though some doubts may perhaps be suggested, from a comparison of some of these with other species, yet, on the whole, as a general position it may be admitted. Of the gallinæ, some species of every genus are occasionally eaten, and perhaps every one will afford a moderately mild food. Even the ostrich, when young, is a delicacy. The most common species, which adorn the tables, belong to the genus *phasianus* Lin. the domestic fowls; the *meleagris*, the turkeys; *pavo*, the pea-hen; *otis*, or the buzzards; and the *tetrao*, including the partridges, black

cocks, &c. The quail belongs to this genus. These are all graminivorous. The rails, particularly the *rallus* grex, connects them with the grallæ on one hand; the pigeons and larks with the passeræ on the other. The grallæ afford a more sapid food, and we suspect often a more digestible aliment. The rails we have already mentioned; but the edible species of scolopax (the woodcocks and snipes) are more commonly known and esteemed. The genus tringa, including the sand-pipers, and the knots, may be next arranged; and the charadrius, the plover, is scarcely inferior. Some of the other genera are seldom eaten; and the herons and curlews, though not rejected, are not, on account of their fishy flavour, to be recommended when the digestion is weak.

The columbine race resembles, rather in appearance than in qualities, the gallinæ. The young pigeon is, however, easily digestible; but the older birds are dry and insoluble. We have had reason to believe, that none of the columbæ, when they exceed half their usual size, are easy of digestion; and, when full grown, they have often created uneasiness in the stomach. The *lauda* Lin. are often eaten, and the flesh of the *a. arvensis* is safe to be of a delicious flavour in the southern climates; though accused, perhaps without reason, of being injurious in calculous complaints. The greater number of the passeræ are too small to enable us to determine their relative digestibility, as they cannot wholly form a meal, even for an invalid. We have reason to think them in general easily digestible.

The *anseræ* usually afford a gross indigestible food, unless in the earliest periods of their existence. The genus *anas* offers the greater number of the edible species. All species of the *anas* have been occasionally eaten; but the wild kinds are often lean, hard, and fishy; the tamer ones, which have been fed on grain, are sapid; and, when young, easily digested. The teal is the most delicate of the wild kind, and the young duck of the tame *anseræ*. Of the auks, some of the younger kinds, when cured by smoke, are eaten by the inhabitants of the northern regions; and the egg of the arctic auk is said to be delicious. The penguins also have been eaten from necessity, and their eggs commended; but we find only among common foods the *pelicanus bassanus*, the solan goose from the Bass island. Some of the shags, also, which belong to this genus, have been occasionally employed as food. Of the gulls, one species is mentioned by Sauer, as delicious, and not unlike the turkey.

Of the *pica*, some of the macaws have been eaten; but the flesh is hard, dry, and indigestible: those, however, which feed on vegetable substances, must be excepted. The *psittacus pertinax*, for instance, the yellow-faced parroquet, and the *p. jaguilma* and *cyanolyseos*, two species observed by Molina, in Chili, have been used as food; the last are said to be delicious. The *buceros hydrocorax* of the Molucca Islands, which feeds on nutmegs, has been considered as a delicate high flavoured food. One species of the wattle bird, the *glacotis cinerea* Lin. is mentioned by Dr. Foster as edible; and many persons are fond of the young of the *corvus frugilegus*, the rook: yet their colour and flavour must be rendered less disgusting, by previously soaking them in milk. It is indeed doubtful whether this species of *corvus* really feeds on corn; the more

probably devour the larvæ of insects, raised by the plough; but some other species certainly feed on grain, though we find only the chough or Alpine crow, *c. pyrrhocorax* Lin. reckoned among the foods. Among the rollers, the European species, *coracias garrula* Lin. is only eaten; but of the *oriolus* many species have been employed as food. As the greater number feed on grain, we may find the edible species numerous. Among the other picæ, we perceive only the golden woodpecker, the *picus auratus* Lin. and a species of *alcedo*, *a. galbula*, recommended as eatable. The accipitres have never been employed as aliment; but some of the shrikes, which feed on grain, and resemble the picæ in their manners, may perhaps afford wholesome nourishment.

The AMPHIBIA approach, in their digestible nature, the younger animals of the mammalia and aves; yet the more luscious and fatty parts render them sometimes gross, and not easily assimilated. The muscular flesh of the turtle and tortoise is not unlike veal; their tendons, ligaments, and fat, are more indigestible. Different species of the *testudo* are employed as food; among which the green turtle, and the ferocious tortoise of America, are the most delicate; and the *t. caretta* the driest and worst flavoured. The land tortoise is neither a very delicate nor easily digestible food, though it has not been employed in its best state. Of the lizards, the crocodile is said to be eaten by the Moors, but we know not the nature of its meat: its eggs are well flavoured and digestible. The eggs of the guana, the *l. iguana*, are said to have no yolk, and not to be coagulated by heat. The meat is digestible, and, in the opinion of some authors, preferable to fowl. The viper has been reckoned an easily assimilated and a nourishing food: its broth has been consequently employed as a restorative after fevers. It is probably an easily digestible substance, or it would not so long have maintained its credit; and it may now be lost rather from varying fashions than any inconvenience resulting from it. The buffalo snake, *boa constrictor*, is enumerated among the edible amphibia; but its peculiar nature is not mentioned. It probably does not greatly differ from the viper. The frog is well known to be a light, digestible food, and greatly to resemble delicate veal. The green lizard, *lacerta agilis*, is not greatly different. We may here mention a gelatinous esculent substance, which, though the work of a bird, is probably derived from some of the lower orders of animated nature; we mean the nest of the *hirundo esculenta*. It is found in the East India islands, particularly in the caverns near the sea, and is gelatinous, indeed peculiarly rich and luscious; nor have we heard that it creates uneasiness or indigestion.

The sea insects may be next arranged, as they seem to be easily digestible, and occasion less uneasiness than even the lighter kinds of fish. They have been accused of exciting febrile heat and efflorescence on the skin; but these are probably accidental effects from the food they take in. We have found them, in general, light and nourishing. The only sea insects eaten are the species of *cancer*: yet the lobsters, craw fish, prawns, and shrimps, should be separated from the crabs, probably in a scientific, certainly in a dietetic, view. The crab affords a very digestible food; the others are less easy in the stomach. Next to the crab are the shrimp,

the white shrimp, and the prawn, the *c. crangon*, *squilla*, and *serratus*. The lobster is richer as a food (*C. gammarus*); and the *craw fish* still more rich.

The marine vermes are also albuminous and glutinous. They are easy of digestion only in their raw state; for when heated the albumen is coagulated, and not easily assimilated. The oyster and the cockle are the most easy. The muscle, *mytilus edulis*, is next in the order: this animal is suspicious, from the accidents which have followed its use. These are not well understood, and may arise from the habit of the person affected; for, in some constitutions, even the white of an egg boiled will occasion sickness and efflorescence: but it is more probable, that the muscle occasionally feeds on a deleterious insect, which is the real poison. It is, on this account, probably safer to avoid it. The queen is more rich, and the scallop, *ostrea chama*, too luscious for weak stomachs. The borer, *pholas dactylus*, the limpet, the sea apple, *echinus esculentus*, and two species of *sepia*, the cuttle and stocking fish, are seldom employed as food, and resemble, in their nature, the cockle, though more dry and coriaceous; at some seasons indigestible. Of the terrestrial vermes, we eat only the snail, as a mild nutriment: several species have been eaten in hectic cases, with little apparent advantage or inconvenience.

In a dietetic view, FISH are of two kinds, which we may denominate from the most common instances—the whiting and the turbot kind. The flakes of the former are firm and dry; those of the latter more luscious and fat, or more tender and watery. We cannot pursue this distinction through the whole tribe of esculent fish, but shall thus arrange the more common kinds; adding the others, whose qualities are less known, in a more indiscriminate list.

Of the first kind, then, the genus *gadus* affords the most prominent instance. It contains the cod, the ling, the whiting, the haddock, the sea burbot, the pollack, the rawlin pollack or coal fish, the dorsk, *g. cellarius*, and the bibb, *g. luscus*. The meat of these species is firm, solid, and easily digestible; nor is there, in the whole list, any striking exception. The flakes are white, firm, and conchoidal. The genus *mullus* affords a species of a similar nature, though not equally firm. Of these, the firmest is the surmullet, *m. barbatus*, or red mullet; called the woodcock of the sea, both from its superior flavour and from the custom of using the tail as sauce. This fish is easily bruised, and soon spoiled: so that it is little known in this metropolis. The genus *clupea*, containing the herring, sprat, anchovy, and pilchard, are more oily, and less easily digested. The *scombri*, whose most common species is the mackarel, are still stronger, but of a more delicate flavour. The genus *trigla* affords the piper, the gurnard, which is occasionally gray, but generally red, and the sea lantern. These are apparently less gross, but we do not find that they afford an easily digestible nutriment. The *zeus faber*, St. Peter's fish, or the john dorey, (*jean doré*, from its shade of gold mixed with green,) belongs to the whiting tribe; and its connexion, from the firm, flaky flesh, with the whittings, prevented our dividing them into the flat and rounded fish.

There is a class which, from the firm solidity of the flesh, approach the whiting tribe, though often hard

and indigestible; viz. the CARTILAGINOUS FISH. The genus *accipenser* (sturgeon) affords the common sturgeon, the isinglass and caviare sturgeon, and the tube. They are, like the piper, firm, but not easily digestible. The various *skates* are not very dissimilar; and of this genus, *raia*, we find five edible species. We have alluded to the practice of crimping; and, as the skates are usually subjected to this operation, we shall now explain it. While the irritability of the muscles remains, the fish is cut across in a direction perpendicular to the fibres: these portions consequently contract, and the fish is more firm. It is chiefly employed in the skate, because the fibres easily separate longitudinally; and, from their want of firmness, much of the flavour is lost. The same operation is sometimes performed on the whiting and salmon; but this is only useful when these fish are long kept. They are firm when taken out of the water; but the fat separating diminishes the connexion of the longitudinal fibres, and renders the flavour less pleasing. The *lamprey* is one of the cartilaginous fish which belongs to this class. It is high flavoured, but gross and indigestible. Three species are eaten, but the sea lamprey is preferred. The *fish-fowl*, *lophius piscatorius*, derives its name from the resemblance of its flesh to that of chicken; and the *lumpfish*, *cyclopterus lumpus*, is not very different. The *conger eel*, when divested of its rankness by soaking and salt, approaches animal substances, and particularly hard, ill-fed veal. The *shark*, of which many species are eaten, is still more dry, hard, and disgusting.

The *turbot* tribe are much more alluring; but they are confined to one single genus, the *pleuronectes*. The softest and most digestible is the plaice; then follow the flounders, the dabs, the sole, the holibut, the brill, and the turbot, nearly in the order of their digestibility. The holibut, indeed, is dry and woolly; the brill is often similar; yet, when fresh, they appear sweet to the taste, and seem to be easily assimilated. We find some other edible species, of which we have no experience, viz. two species of *sparus*, the gilt and laxative fish; two of *labrus*, the sea pullet and sea peacock; the *sea pike*, *esox bellona*; the *trachinus draco* (the weaver), mentioned with high encomia by Duhamel; and the *mulga cephalus*, whose ova make the Italian botargo. The caviare sturgeon furnishes a similar substance from its roe; but it is hard, dry, and indigestible.

We have, in compliance with the arrangement of some respectable authors, separated the river from the sea fish: we think, however, without reason; for several river fish are truly inhabitants of the sea, and are caught in rivers while reaching a secure asylum to deposit their spawn, or while returning to the sea. The young ones are also occasionally caught in their way to their natural habitation, the ocean; and, we suspect, have been sometimes considered as distinct species. River fish have been considered as more easy of digestion than those of the sea. If we advert to the distinction just noticed, we should form a very different opinion. We have hinted that the river fish are only the degenerate offspring of those of the sea; and, were this a place for such discussions, we could render this opinion highly probable. We have seen the herring in some inland lakes of Asia; but in a state that we could scarcely recognise it, except by its determined specific characters. The trout of the sea is greatly superior to

that of rivers, and the salmon from the ocean is a fish of much higher flavour than when it has resided some time in fresher water. To this there is only a single objection; the char, from the lakes of Westmoreland, is a fish of considerable flavour, and equals or excels the other species of *salmo*, to which it belongs.

The chief genera of what are styled river fish are the *salmo* and *cyprinus*, though the last is only strictly such. From the genus *salmo* we select the salmon, the salmon trout, the trout, the char, the salmarine, the redling, the grayling, the huch, the salvelin, the smelt, the white fish, and the oxyrinchus. We have placed them nearly in the scale of general estimation; but tastes differ, and these we cannot dispute: excepting the salmon, they are of sufficiently easy digestion; but this fish, from its richness, if kept more than a day, disagrees with weak stomachs; and the fat, rising to the surface, occasions sickness and disagreeable eructations. From the genus *cyprinus* we receive the carp, the tench, the roach, the dace, the gudgeon, with many similar fish of little estimation, which, in general, owe their attractions to the cook, as, without the most poignant sauce, they are dry and insipid. The *perca* (perch) affords several species, not more attractive. The wolf fish, and the ruffe, *p. labrax* and *cernua*, are two of these, little valued. The *pike*, the devouring monster of the river or pond, scarcely admits of a better character; and the stickleback, *gasterosteus aculeatus*, and the shad-fish, *silurus glanis*, the giant of the rivers, are chiefly sought after when sea fish are not to be procured.

There are two river fish which deserve a higher rank, the river burbot (*gadus lota*), and the eel. Of the former, the liver, like the trail of the surmullet, is a peculiar delicacy; and the latter is a fish often very rich and highly flavoured; nor have we found it an inconvenient food, even in weak stomachs. The eel, however, is very strictly a fresh water fish; and its ova preserve the principle of life so long, that, in India, the tanks, after having been dry many months, when again filled, are said soon to swarm with eels. Some small fish, as the *sand eels*, the *minnows*, the *groundlings*, and *weather fish* (*cobitis barbatula* & *fossilis*), scarcely deserve notice as articles of diet. These resemble the turbot in the structure of their flesh, while the other species approach the firmer flakes of the whiting tribe.

The animals which connect the inhabitants of the sea with those of the land are the CETACEOUS TRIBE, differing from fish in their structure, though adapted for the same element in other respects. We find among the edible cetacea the *balena mysticetus* and *physeter*; the nord caper, and the fin-fish. The flesh of the whale is in general hard and coriaceous; near the tail it is more succulent. The Russians, in the Fox Islands, who eat it, ascribe to this aliment a deleterious effect, producing an offensive perspiration, and irritating the urethra so as to produce a disease resembling gonorrhœa. The Japanese, on the contrary, prefer it as a strengthening aliment, and chiefly eat it when engaged in any laborious occupations. The Greenlanders eat the skin and the fins of the nord caper, and, in the early periods of the whale fishery, the Basque sailors commonly lived on the meat of these animals. Captain Colnet tells us, that the heart of a young whale was considered by his crew as a peculiarly delicate food.

The muscular fibres must be obviously hard and dense, since, when the whale is not fat, or after the fluid oil has escaped, the flesh sinks in the sea like a heavy stone. The *monodon monoceros*, and two species of *dolphin*, d. *phocæna* and *delphis*, have been occasionally eaten, but are hard and indigestible.

Other animals that occasionally inhabit the ocean are sometimes eaten. The *trichecus manatus* is mentioned as a highly flavoured food, particularly the northern variety. The fat is employed as butter. The flesh of the t. dugong, the *Indian walrus*, resembles, it is said, that of the ox. The lips and snout, boiled to a jelly, are considered as a delicacy by the Tshutski. The meat of the *phocæ* is also said to be wholesome and pleasant. The *p. ursina* and *vitulina* (sea bear and sea calf) are preferred; though the *sea lion*, *p. leonina*, is occasionally eaten. The meat of the sea calf is said to be fat and watery, and to soon cloy. The flesh of the sea lion is dry and fishy. The flesh of the ursine seal is blue, but when the animal is young it is well tasted. The *mustela lutris*, the sea otter, is mentioned among the animal foods; but we know not its quality, or the authority on which its alimentary properties are founded. The animal, when young, we are told by Sauer, is as delicate as a sucking pig, and resembles it. It may perhaps be proper, in this place, to notice the animals which live very commonly in water, viz. the *beaver* and the *river* or *fish otter*, the *castor fibra*, and *mustela lutra* Lin. The flesh of these animals, however, furnishes our food so rarely, that our experience of it must be limited. The flesh of the beaver has been thought to resemble beef. It is hard and difficult of digestion, and the smell is offensive. The tail is, however, an exception; as it is tender and more delicate. The native Canadians often eat it, and in Lorraine it is said to have been no uncommon food. When well seasoned, it is supposed to resemble lampreys. The flesh of the otter smells and tastes of fish; it is dry and coriaceous; eaten only by the monks when fish cannot be procured. In this scarcity they sometimes even employ the grossest fishy wild fowl.

We now arrive at the QUADRUPEDS, the class from which the greater portion of our food is taken. In a dietetic view, the *pecora*, with ungulated feet, are the most easy of digestion, and perhaps the most nutritious; and it is a rule, apparently general, that the further the claws are extended, till they become palmated, the less digestible and wholesome is the food which the animal affords. We have said that the flesh of wild animals is more digestible than that of tame ones. The genus *cervus* claims the pre-eminence; and perhaps not a single species exists which is not, in some country, a delicacy, if well fed: many, in the more emaciated state of a wild animal, are highly esteemed. The various species of the *sheep* follow: nor need we stop to enumerate the warm commendation of the tails of the African sheep, or the delicate flavour of the Siberian. In general, the small wild kind are preferable: the larger and fatter varieties are rank and less digestible. The modern improvers, who have covered the muscles with immense loads of fat, have not rendered the flesh of a superior flavour, or more ready solubility. The goat, so nearly allied to the sheep, should be next mentioned, though probably not the next in the view of its digestibility. Our praises must be limited to the ani-

mal in its earlier periods, when most of the species afford a delicate nutriment. When older, the flesh is rank, hard, and dry. The *antelopes* are not equally excellent; and indeed many of the species have not been employed as food. The *a. rupicapra*, gnu and *sylvatica*, are particularly commended. Some of the other species, particularly the *a. sagea*, are scarcely eatable: many are rank, and have the offensive smell of musk.

The genus *camelus* affords species so nearly resembling the sheep, that it should certainly be placed at no great distance. We allude to the sheep of Peru and Chili, which wander over the immense chains of the Andes. The lama of Buffon, the *c. glama*, *c. arcuacanus*, *vicugna*, and *paco*, afford a meat of high flavour, and very digestible. The flesh of the *c. huanucus*, discovered by Molina in Chili, is more hard and insoluble; though, when young, highly esteemed. The camel and dromedary (*c. bactrianus et dromedarius*) have always been highly esteemed in the East, as food. The Arabians consider the latter, usually called the camel, as the greatest delicacy. The rank odour of the musks (*moschus* Lin.) has prevented many of the species from being employed as diet; and we find only the *m. moschiferus*, the Thibet musk, spoken of with approbation. The meat of the younger animals is of a delicate flavour. Of the *ox* we need scarcely speak; and of its various species, many of which are varieties only, the common ox is almost exclusively eaten. The flesh of the *b. moschatus* is strongly perfumed; that of the *b. gruniens* hard and indigestible, unless in its earlier period of life. Of the Cape ox (*b. cafer*), the flesh is coarse, but juicy, and of a wild taste.

The genus *equus* is of a similar nature. Policy forbids the horse to become an article of food; yet, among the Tartar hordes, the horse and the mule also are articles of diet; probably in their younger state. The Mongul and Tungusian Tartars admire the flesh of the *equus hemionus*, which ranges in a wild state, between the borders of Thibet and China. Even the *ass*, in its younger period, is, we believe, occasionally eaten. The zebra has never been an article of diet.

The *hippopotamus* connects the horse and the hog. Both its species, the one resembling the horse, *h. amphibius*, the other more nearly approaching the sow, are eaten; the first by the Africans, particularly the Ethiopians; the second by the inhabitants of the shores of the vast river of the Amazons, where the animal abounds. Either would scarcely suit an European palate, as the flesh is dry and coriaceous.

The feet of the *hog* are more minutely divided, and, as an aliment, it is gross, often indigestible. It has been considered as peculiarly aphrodisiac, though without sufficient foundation. Linnæus once supposed it particularly injurious in occasioning a relapse of intermittent fevers, for this was the meaning of an obscure phrase in the system of nature, *cinconæ criticis obest*. The suspicion however seems void of any foundation, and in the later editions it is, we see, omitted. The Chinese variety is the most delicate in flavour, but each is gross, and in weak stomachs occasions inconvenience.

The Guinea pig has, within our own knowledge, formed an article of diet, but was not highly relished. The *s. tajassa*, the Pecary, or Mexican hog, is said to be alimentary, if eaten immediately after the animal is killed. It is a more cleanly animal, and feeds, at least in

part, on grain and fruit ; partly indeed on reptiles and serpents. The *Ethiopian hog* has, we believe, been never eaten : the *s. baby russa*, the Indian hog, which nearly equals a stag in size, is said to afford a good food.

The feet are still more divided in the *GLIRES* ; and they afford in few instances either a wholesome or a delicate nutriment. The hare forms the chief exception ; which is easily digestible, and when young a delicate and light food. The rabbit merits similar commendations ; and authors have styled it a soluble meat. But on this point we have our doubts ; and should it ever be so, the animal must be young. The flesh of the Alpine hare, as well as of the Russian rabbit, is less delicate ; but that of the small hare of Chili is said to be of a superior flavour. There are some other species, of which we have received no information. The genus *hystrix* must be next mentioned. It resembles the hog ; and the crested as well as the Brazilian porcupine are said to afford a salutary nutriment. The *h. dorsata* and *macrocoura* seem never to have been used as food. The species of *cavia* resemble, in qualities and flavour, the rabbit. The *c. acuschy* and *aguti*, with its varieties, are most commended. The *c. capybara* is of a less delicate kind. The genus *hyrax* is nearly connected with the *cavis*, but neither of the species have supplied any nation with aliment.

The beaver, of which we have already spoken, connects the *cavia* with the *mures* ; and the *mus coyhus* greatly resembles it ; but we cannot find that it has been ever eaten. The other species of *mus* are so disgusting in their appearance and manners, that they have been eaten only from necessity. We have seen more than one person who has declared, that young mice and rats are little inferior to rabbits ; but we doubt their having employed them as food, and perhaps

Rats and mice, and such small deer,

Have been Tom's food for seven long year,  
may be considered as a poetical hyperbole to enhance the supposed misery of poor Tom's situation. Some of the species have been certainly eaten from necessity, and Pallas has told us that the Yakuti employ a few of these as food.

The *arctomys*, allied to the rats, is undoubtedly edible ; and some of the species are peculiarly delicate. In Switzerland, and in the North of Asia by the Yakuti, the *marmotte*, *a. marmota*, is esteemed a tender highly flavoured food. The *bobak* of Poland is little inferior. The *a. citillus* is inferior as an aliment. Of the other species we have no experience, nor can we find any account. Many of the squirrels are eaten, and some of them have been reckoned a delicate food, particularly that which in the arctic regions is styled *belka* : those, which are separated by Linnæus, and united under the genus *myoxus*, have, we believe, been never eaten. The genus *dipus*, which includes the kangaroo, affords, besides the largest quadruped of New Holland, many edible species. They afford, particularly when young, a tender and easily digestible aliment.

Among the *bruta*, we find some species of armadillo used as food ; and the flesh of the rhinoceros is said to be eaten by the Moors and Hottentots : it must be however in the earlier periods. We recollect hearing that the trunk of the elephant is delicate nourishment, but we cannot discover our authority.

Among the *feræ*, the lion is pre-eminent. Bruce speaks of it as food ; and it is said that Shaw mentioned

its having been eaten, but was fearful of publishing what would be thought incredible. It is now ascertained, that the flesh of the lion forms occasionally the food of the Africans. The *cat* is said, by Gesner, to be eaten in Switzerland ; and Nobleville, in his continuation of Geoffroy, remarks, that many people think cats as great a delicacy as rabbits. If we may credit Le Sage, they are sometimes substituted for rabbits in Spain. *Dogs* are, we know, eaten in the islands of the Pacific Ocean, but apparently in no other country. The young of the *bear* are said to be tender and delicate ; and the *badger*, a species of the same genus, when young and well fed, is said to be excellent, and is eaten at the best tables in Italy and Germany.

One order only remains, the *primates* ; and, unfortunately, man has, in some instances, fed on man. The savage devours his enemies from revenge : the half-famished wretch clings to life, by eating a devoted victim of his own kind. In the South Sea Islands man once was employed as food ; and in New Zealand probably it is still a banquet in great estimation. We apprehend human flesh resembles, in taste as in look, that of the hog ; nor is it said to be unpleasing or indigestible. We need not enlarge on this subject ; to fill the picture, it should furnish one object ; to avoid disgust, it should be immediately removed.

We add the following list of alimentary substances from Dr. Darwin's *Zoonomia*, in the order of their nutritious powers, beginning with the most nutritive, and proceeding to those less so :

- I. *Cervus elaphus*, the stag.
- C. dama*, the fallow-deer.
- C. capreolus*, the roebuck.
- Bos taurus*, the ox.
- Capra ovis*, the sheep.
- Lepus timidus*, the hare.
- Anas anser*, the goose.
- A. boschas*, the duck.
- Scolopax rusticola*, the woodcock.
- S. gallinago*, the snipe.
- Tetrao rufescens*, red game.
- T. tetrix*, black game.
- Ostrea edulis*, oysters.
- Cancer gammarus*, lobster.
- C. pagurus*, crab.
- C. squilla*, prawn.
- C. astacus*, cray-fish.
- Fungi esculenti*, mushrooms.
- Murena anguilla*, eel.
- Cyprinus tinca*, tench.
- C. barbus*, barbel.
- Salmo eperlanus*, smelt.
- Pleuronectes rhombus (maximus)*, turbot.
- P. solea*, sole.
- Testudo mydos*, turtle.
- Caro agnina*, lamb.
- *vitulina*, veal.
- *porcelli*, sucking-pig.
- Meleagris gallopavo*, turkey.
- Tetrao perdrix*, partridge.
- Phasianus colchichus*, pheasant.
- *gallus*, fowl.
- Esox lucius*, pike.
- Perca fluviatilis*, perch.
- Salmo fario*, trout.
- S. thymalus*, grayling.

*Cyprinus gobicus*, gudgeon.

II. *Triticum*, *hordeum*, *avena*, *pisum*, *solanum tuberosum*, *rapa*, *daucus carota*, *brassica oleracea*, *b. brocoli*, *asparagus*, *cynara*, *scolymus*, *spinacia*, *beta*, *poma*, *pyra*, *piruna*, *mala armeniaca*, *persica et aurantia*, *fraga*, *uvæ*, *melones*, *cucumeres*, *figus siccate*, *uvæ passæ*, *saccharum mel*, &c.

III. *Aqua fontana*, *rivalis*, *carbonas calcis*.

IV. *Aer atmosphericus*, *gaz oxenium*, *azotum*, *acidum*, *carbonicum*.

V. *Balnea*, *enemata* *nutrientia*, *transfusio sanguinis*.

VI. *Condimenta*.

On this arrangement we shall make no remarks. It is the offspring of fancy rather than observation; and an obvious distinction is neglected, viz. that between the degree of nutrition and the facility of digestion. Some of the generic names differ from ours, which are those of Gmelin's edition of the *Systema Naturæ*.

ALIMENTARY CANAL. The whole tract of intestines, including the stomach.

ALIMENTARY DUCT. See THORACIC DUCT.

ALIMOS. Common liquorice.

A'LIMUM. See ARUM.

ALINDE'SIS, or *αλινδος*, (from *αλινδρα*, *volvō*). A bodily exercise, which seems to be rolling on the ground, or rather in the dust, after being anointed with oil. Hippocrates says, that it hath nearly the same effects as wrestling.

ALINTHISAR. See HYPOSTAPHYLE.

ALIO'CAB. See AMMONIACUS SAL.

ALIPÆNOS, } (from *α*, neg and *λιπαινειν*, to grow

ALIPANTOS, } fat). Any external dry remedies that have no fat in them.

ALIPA'SMA, (from *αλειφα*, to anoint). A powder which, when mixed with oil, is rubbed on the body to prevent sweating.

ALIPE, *αλιπη*. Remedies for wounds in the cheek to prevent inflammation. Galen.

A'LIPILI, (from *alarum pilos*, evelientes.) Servants so called from their pulling off hairs from the arm-pits with tweezers, from persons in the baths.

ALIPOW, a species of turbit found near Mount Ceti, in Languedoc. It is a powerful purgative, used instead of senna, but much more active.

ALI'PTÆ, (from *αλειφα*, to anoint). Servants of the baths, whose office was to anoint the persons after bathing.

ALISANDERS. See SMYRNIUM.

ALI'SMA MATHI'OLI. See DORIA.

ALI'SMA, (from *άλς*, the sea, the name of many aquatic plants); called *Acúron*. A name of Doria's wound-wort, and of the German leopard's-bane. See DORIA NARBONENSIS, and ARNICA MONTANA.

ALI'STELES, (from *ἅλς*, salt). See AMMONIACUS SAL.

A'LITH. See ASAFETIDA.

ALITURA, (from *alo*, to nourish). See NUTRICATIO.

ALKAFI'AL. ANTIMONY. See ANTIMONIUM.

A'LKAHEST GLAUBERI, i.e. SALES ALKALINI. See ALCALI.

A'LKALE. The FAT of a HEN.

A'LKALI FIXUM, SAL. i.e. KALI. See ALCALI.

A'LKALI VEGETABILE FIXUM CAUSTICUM. See KALI.

ALKA'LIA. See VAS.

A'LKARA, or ALCARA, (ALKARAGH, Arab). See CUCURBITA.

ALKA'SA, (ALKASAH, a *cup*, Arab). } See CRUCI-  
ALKAZO'AL. } BULUM.

A'LKAUT. See ARGENTUM VIVUM.

ALKEKE'NGI, (ALKAKANGI, Arab). WINTER-CHERRY; also called *halicacabum*, *solanum vesicarium*, *vesicaria vulgaris*.

The species used in medicine is the *physalis alkekengi* Lin. Sp. Pl. 262.

It grows wild in France, Germany, and Italy, and thrives well in our gardens. The fruit ripens in October, and continues to December, when the plant dies to the ground.

These cherries have an acidulous and not unpleasant taste, with a bitterishness; but their covering is very bitter.

They are diuretic, but neither heat nor irritate; five or six cherries, or an ounce of their juice, is a dose; and if given in the strangury from cantharides, a speedy relief is said to be obtained. Hoffman recommends them in hæmoptysis, and some authors have thought them useful in dropsy. ʒij. of the berries infused in a pint of water, are extolled in the jaundice; but they are rarely called for in the English practice. The plant itself is of a poisonous class, and consequently suspicious; yet, as they seem to combine an anodyne with an astringent quality, they may deserve a trial.

ALKE'RMES, (ALKARMAH, Arab). See CHERMES.

ALKE'RVA. See CATAPUTIA.

A'LKES. BURNT BRASS. See ÆS USTUM.

A'LKETRAN. See CEDRIA.

ALKI'BRIC, A'LCHI'BRIC, A'LCHIBERT, A'GIBIC, A'LKIBIC, A'LCHABRIC, A'LKIBRIE. According to some, the sulphur vivum is meant by these words; but others say they signify an incombustible sulphur.

A'LKIN. See CLAVELLATI CINERES.

A'LKIR. SMOKE of COAL.

A'LKITRAM. See PIX LIQUIDA.

A'LKOSOR. See CAMPHOR.

A'LKI PLU'MBI. It seems to be the cerussa acetata. See PLUMBUM.

ALL-HEAL. See HERACLEUM and STACHYS.

ALL-SPICE. See MYRTUS.

A'LLABOR. LEDA. See PLUMBUM.

ALLANTOIDES, ALLA'NTOIS. The membrane, which forms part of the secundines, (from *αλλας*, a *sau-sage*, or *hog's pudding*, because in some brutes it is long and thick, and *ειδος*, *likeness*). It is also called *allantoides farciminalis*, the URINARY MEMBRANE; but its existence in the human species is generally denied. If any anatomists have ever demonstrated, not one of them has given a distinct figure of it; all the engravings designed to represent it are too incorrect to afford us a distinct idea. Dr. Hunter, in his lectures, absolutely denies the existence of this membrane, except in brutes.

Dr. Hales in the Phil. Trans. Abr. vol. iv. and Mons. Litre in the Mem. Acad. de Sciences, 1701.

ALLARI'NOCH. See PLUMBUM.

ALLELU'IA, (HALLELUJAH! *praise the Lord*. Heb. *wood-sorrel*, so named from its many virtues). See ACETOSA.

ALLEGER, ALE AIGRE, VINEGAR made of ale. It

is almost the only vinegar now employed in this country.

A'LLENCE. See STANNUM.

A'LLIAR ÆRIS. A term used in preparing the philosopher's stone, to signify philosophical copper, which is also called water of quicksilver, white copper, and many other names.

ALLIARIA, (from *allium* garlic; so named from the likeness of its smell and taste to garlic). SAUCE ALONE, or JACK BY THE HEDGE; also called *hes asininus*, and *hesperis allium*. It is the *erysimum alliaria* Lin. Sp. Pl. 922.

The leaves are somewhat acrid, and of a garlic smell; on drying they lose much of their scent, and also of their taste. Its medical virtues are similar to those of the onion tribe, but the plant is not much in use. Their great acrimony renders them occasionally stimulant, and they are probably, as has been said, diuretic and errhine. Externally they have been supposed useful in putrid ulcers.

A'LLICAR. See ACETUM.

ALL'COL. See PETROLEUM.

ALLIGATU'RA, (from *ad*, and *ligo*, to bind). Scribonius Largus uses this word for a *ligature* or *bandage*. See FASCIA.

ALLIO'TICUM, (from *αλλιωω*, to alter, or vary). Galen. An alterative medicine, consisting of various antiscorbutics.

ALLIUM, (either from *oleo*, to smell, because it stinks, or from *αλειω*, to avoid, as being unpleasant to most people). COMMON GARLIC. Called also, from its antiputrescent property, *theriaca rusticorum*. It is the *allium sativum* Lin. Sp. Pl. 425. Nat. Ord. *Liliaceæ*.

It grows wild in Italy, Sicily, and other warm countries; but in England it is raised in gardens from seed: it flowers in July.

The roots only are used in medicine; their virtues consist of a very acrid putrescent volatile oil, combined with a large proportion of mucilage, the principal effect of which is to warm and stimulate the solids, to promote a discharge from the bronchial glands and the kidneys; perhaps in a slight degree to resist putrefaction. Applied to the skin they excite inflammation; and sometimes raise blisters: they are used as a stimulating epithem to the soles of the feet, in the low stage of acute fevers, for raising the pulse and relieving the head. Sydenham says, that garlic excels all other applications for occasioning a derivation from the head in fevers of any kind; and he adds, that the efficacy of garlic is more speedy than that of cantharides, without a dissolution of the juices as when the common blistering plaster is applied. This, however, we now know to be hypothetical merely. Garlic beat up with an equal quantity of soft bread is occasionally applied to the feet, but is found of little service, except in children, who cannot swallow any medicine. It certainly is absorbed, as it affects the breath, and consequently may be useful as an expectorant.

Sometimes the garlic cataplasm causes much pain, but this would not happen if it was removed as soon as an inflammation appeared, and immediately after another cataplasm of bread and milk to supply its place.

The cloves of fresh garlic are bruised, and applied to the wrists as a cure of agues; and to the bend of the arm to cure the tooth-ach: held in the hand they are said to relieve hiccough; beat with common oil into a

poultice, they resolve sluggish humours; and if laid on the navels of children, they are supposed to destroy worms in the intestines.

If garlic is taken inwardly, its action manifests itself through the whole habit, the breath, urine, and the matter of perspiration are scented with it. It assists digestion, and is certainly heating and inflammatory to the whole system. Its diaphoretic and diuretic powers have been useful in dropsy: it is a remedy for the scurvy; and in pituitous, and even in spasmodic asthma that require expectoration. It has been said to be efficacious even in subduing the plague, and its stimulant powers have been employed for preventing the recurrence of intermitting fevers. Bergius says, quartans have been cured by it, and he begins by giving one bulb, or clove, morning and evening, adding every day one more till four or five cloves be taken at a dose. If the fever then vanishes, the dose is to be diminished, and it will be sufficient to take one or even two cloves twice a-day, for some weeks. This author also recommends it in deafness, and Dr. Cullen is inclined to believe it may be beneficial, as he has found the juice of onions in such cases very useful. A clove or small bulb of this root wrapt in gauze or muslin, and introduced into the meatus auditorius, is the mode of applying it in these cases. Some authors have considered it as a lithontriptic. Where people cannot take the garlic in substance, the best forms are either the syrup or oxymel. See Cullen's *Materia Medica*. If cows happen to eat the leaves of garlic, their milk will be strongly impregnated with its flavour.

In cold phlegmatic habits it is particularly useful, by its corroborant, expectorant, and diuretic effects. In the asthmas of such constitutions it is more eminently useful, and in these chiefly it has been supposed to possess a lithontriptic power.

Hoffman says, that if the cloves of fresh garlic are boiled in milk, they are one of the best anthelmintics; but garlic should be taken in the form of a pill or a bolus, fresh made. The syrup and oxymel of garlic have been thrown out of the British pharmacopœias. Swallowing the clove of garlic entire, or cut into pieces, after having been dipped in oil, is considered as a very effectual mode of administration.

In hot bilious constitutions garlic is improper; for it produces flatulence, head-ach, thirst, heat, and other inflammatory symptoms: a free use of it soon promotes the piles in habits disposed to this complaint.

In drying it loses nine-fifteenths of its weight, but fresh or dry it equally gives out its virtues to boiling water, vinegar, or brandy, though it has been suspected that its powers are somewhat weakened by drying; and an infusion in the latter is highly useful to relieve or prevent uneasiness in the stomach and bowels from gout.

The oil, or active principle, is small in quantity, yellowish and ropy; but the juice may be inspissated into an extract by a gentle heat.

Rectified spirit of wine, digested on dry garlic roots, extract their virtues more readily, and more perfectly, than either water or vinegar. For those called

ALLIUM ALP'NUM,	} See OPHIOSCORODON.

ALMARKASI'TA. See ARGENTUM VIVUM.

ALMAR'TACK. POWDER OF LITHARGE.

ALMELILE'TU. A word used by Avicenna to express a preternatural heat less than that of a fever, and which may continue after recovery.

ALME'NE. See SAL GEMME.

AM'ISA. Musk. See MOSCHUS.

ALMISA'DAR, or ALMIS'ADIR, or ALMIZ'A-DAR, or ALMIZ'ADIR. See AMMONIACUS SAL.

ALMISA'RUB. EARTH. See TERRA.

ALMIZ'ADIR. See ÆRUGO.

ALNABA'TI. In Avicenna and Serapion, means the *siliqua dulcis*, a gentle laxative.

A'LNEC. TIN. See STANNUM.

A'LNERIC. See SULPHUR VIVUM.

A'LNUS. (*Alno*, Ital.). THE ALDER TREE. *Betula alnus* Lin. Sp. Pl. 1394.

A'LNUS ROTUNDI, FOLIA GLUTINOSA VIRIDIS, C. B. THE COMMON ALDER TREE, called *amendanus*.

THE BLACK ALDER is the *Rhamnus frangula* Lin. Sp. Pl. 280; called also *Avnus*.

All the parts of this tree are astringent and bitter, the bark is more astringent; a decoction of it hath cured agues, and is often used to repel inflammatory tumours in the throat.

THE BLACK OR BERRY-BEARING, ALDER, is a shrub found in the moist woods. The inner yellow bark of the trunk or root has a bitter and styptic taste:

given to 3ij. vomits, purges, and gripes; but joined with aromatics it operates more agreeably; though an infusion, or decoction of it in water, inspissated to an extract, acts yet more mildly. It is said also to be diuretic and anthelmintic; externally, useful in itch and in varices of the anus. The berries of this species of alder are purgative; they are not in use under their own name, but are often substituted for buckthorn berries. The berries of the black alder, however, have a black skin, a blue juice, and two seeds in each; while the buckthorn berries have a green juice, and commonly four seeds. The error is not, however, of much consequence: the plants belong to the same genus, and the berries do not differ greatly.

ALOE, (AHLAH, *growing near the sea—αλον*); called also *Fel Naturæ*; a plant which affords the purging gum of the same name; all the species have thick succulent leaves like those of the house-leek, but much larger, and run two or three feet high. The best is said to grow in India, but all Asia produces excellent plants; and in most warm climes they are found, as in the West Indies, &c.

ALOES GUMMI, GUM ALOES. This is the inspissated gum of the whole plant described above. It is reported that Alexander, landing on the island of Succotora, or Zocotria, at the mouth of the Red Sea, in one of his expeditions, took notice of the *aloe* plant, and from that it was brought into use, and called *Succotorina*.

Of the gum we have three kinds in the shops.

1. A'LOE SUCCOTO'RINA, vel ZOCOTORINA. SUCCOTORINE ALOE.

It is imported from the island Succotora, in the Indian Ocean, wrapped in skins; it is obtained from the *aloe spicata*, according to Thunberg. This species is not in the edition of the species published by Linnæus, but occurs in the Supplement, p. 205, and is the second species of the 659 genus of Willdenow's edition. Its natural order is the *Liliaceæ*. The gum is bright on its surface, and of a reddish colour, with a purple cast; but when powdered it is of a golden hue: it is hard and friable in very cold weather, but in summer it softens very easily betwixt the fingers. It is extremely bitter, and also accompanied with an aromatic flavour, but not so much as to cover its disagreeable taste. Its scent is rather agreeable, being somewhat similar to that of myrrh. It is said to be the juice exuding from an incision of the leaves.

2. ALOE HEPATICA, vel ALOE BARBADENSIS. THE COMMON, BARBADOES, or HEPATIC ALOES, called *kadanaku*, and *catevata*, is from the *aloe perfoliata* Lin. Sp. Pl. 458. The best is brought from Barbadoes in large gourd-shells; an inferior sort in pots, and the worst in casks. It is darker coloured than the Succotorine; drier, and more compact, though sometimes that in casks is soft and clammy; to the taste it is intensely bitter and nauseous, being almost totally without that aroma which is observed in the Succotorine; to the smell it is strong and disagreeable.

3. A'LOE CABALI'NA, vel ALOE GUINEE'NSIS, HORSE ALOES. It is not easy to believe, as is generally reported, that this is only the more impure part of the Barbadoes aloe, or rather the residuum after the hepatic aloe have been expressed, because the difference does not consist in the purity, but in the quality. It is very distinguishable from both the others by its

strong rank smell; in other respects it so agrees with the Barbadoes species, as to be often sold for it. Sometimes its purity and clearness are such, that it cannot be distinguished from the Succotorine aloë; but either its offensive smell, or its want of the aromatic flavour, betrays it. This aloë is not admitted into the materia medica; but employed by veterinary surgeons.

The general nature of these three kinds is nearly the same; their particular difference only consists in the different proportions of gum to their resin, and in the flavours they possess, which render them more or less pleasant for internal use.

Aloës consist of a small portion of resin, and a large one of gummy matter. Twelve ounces of the Barbadoes aloës yield nearly four ounces of resin, and eight of a gummy extract. The same quantity of the Succotorine yields three ounces of resin, and nearly nine of gummy extract.

The aloës may be purified by solution in water, and an evaporation so immediately after, that the resin may not have time to settle. When it settles, it may be separated by spirit of wine.

The resin of aloës hath but very little scent; that from the Succotorine hath very little taste, from the Barbadoes a slight bitter, and from the caballine somewhat more of the aloëtic flavour.

The gummy extracts are less disagreeable than the crude aloës; that of the Barbadoes smells rather stronger than that of the Succotorine, but in taste is less ungrateful; that of the Succotorine has very little smell, and is scarcely unpleasant to the taste; that of the caballine aloës hath a rank smell, but its taste is not worse than that of the Succotorine.

In the resinous part consists the healing qualities, hence for *external uses* the Barbadoes is the best; *internally*, however prepared, the resin hath very little cathartic power. In the gummy extract resides the purgative, and all the other qualities. The gum of the Succotorine aloës is more irritating and active than that of Barbadoes: its effects are uncertain; but it does not seem to leave a costive habit. In *small doses*, twice a day, it occasions a considerable irritation about the anus, and sometimes a discharge from the hæmorrhoidal vessels. These small doses cleanse the first passages, warm the habit, and promote the secretions. In phlegmatic, sedentary, and cachectic habits, and oppressions in the stomach from irregularity, it is useful; and, in common with bitters and purgatives, has been considered as an *anthelmintic*, but it is so only in cases of ascarides. In all diseases of the nervous tribe, aloës is useful, and is supposed to assist digestion. In jaundice it has been thought a succedaneum for the bile, and its title of *fel nature* has been the cause or effect of this opinion.

Aloës is injurious where inflammation or irritation exists in the bowels or neighbouring parts; in pregnancy, and in habits disposed to piles; from three to five grains are a sufficient dose.

Alkaline salts lessen the purgative quality of aloës; and long boiling quite destroys it.

By means of heat, the crude aloës may be wholly dissolved in water; but the resin is deposited when cold. A mixture of pure water two parts, and proof spirit one part, perfectly dissolves it without heat; though rectified spirit of wine dissolves it most speedily. If water or wine be the menstruum, the aloës becomes tenacious,

and dissolves slowly; in this case, white sand should be previously mixed with the powdered aloës.

Cloves cover the offensiveness of aloës the most perfectly, but are too stimulating. The *canella alba*, or the *cassia caryophyllata*, is preferable.

The pharmaceutical forms of aloës are various. It was for ages fashionable to combine them with myrrh and saffron; a form still in use in the pills styled *Rufus's*. These additions were supposed, though with little reason, to correct their acrimony; but the formula answers every purpose desired in a mild eccoprotic, and consequently still retains its credit. There is little reason for supposing the myrrh and saffron useful, except for the more minute division, and soap answers this purpose, at least as well. In the common aloëtic pill, called from Dr. Anderson, aloës is corrected only by the cardamom seeds.

With alkaline salts, aloës loses its bitterness, probably its efficacy; and when the gummy extract is prepared by long boiling, exposed to the air, it becomes inert; as from the absorption of oxygen its extractive matter is changed to a resin. The resin of aloës, as has been said, is very weakly, if at all, purgative. For the reasons assigned, the volatile aloëtic tincture, viz. aloës dissolved in the volatile alkali, is a very inefficient preparation; and the vitriolic elixir proprietatis, which consists of aloës dissolved in vitriolic æther, is perhaps little superior. Van Helmont's vinum aloëticum alkalinum, appears to be a preparation of greater efficacy. It consists of aloës dissolved in mountain wine, with the addition of kali and crude sal ammoniac. It is not however now employed; and seems to have obtained a great part of its credit from the attachment of the Boerhaavian school to alkaline tinctures, which they considered as saponaceous. In stomach complaints, however, it promises to be of service. In our college we find the pill of Rufus; pil. ex aloë cum myrrha: a similar tincture, styled the compound tincture of aloës; and the aloës dissolved in a weak spirit, the common tinct. aloës. This medicine is also joined with more active purgatives, as the scammony and colocynth, with guaiacum, asafœtida, and iron, to answer the various purposes of a more powerful cathartic, a more effectual stomachic, antihysterical, and emmenagogue. Any other purgative joined with aloës, neither increases its powers nor lessens any inconvenience it may produce. See Cullen's *Materia Medica*, Murray's *Apparatus*, and Woodville's *Medical Botany*.

ALOE rosata; violata; violata tartarea; insuccata; insuccata tartarea. These are old forms, in which the aloës is repeatedly dissolved in the juice of roses and violets, and as often exsiccated by evaporation. When dissolved in the juices of roses, violets, borage, and bugloss, it is styled 'insuccate;' when with the addition of one-third of its weight of cream of tartar, it has the appropriate epithet of 'tartarea.'

For other preparations, whose principal ingredient is aloës, as

ALOEDARIA, ALOEPIANGINA, and ALO-ETICS. Compound purging medicines; so called from having aloes as one ingredient. The aloepiangina contains aromatics.

ALO'MBA. } See PLUMBUM.  
ALO'OC. }

ALO'PECES, (from *αλωπεξ*, the fox,) so are the PSOÆ muscles called, because in a fox they are particularly strong. Lat. *Vulpes*. See PSOÆ.

ALOPE'CIA, BALDNESS, the FALLING OFF OF THE HAIR, (from *αλωπεξ*, a fox,) because the fox is subject to a distemper that resembles it. *Athrix*, *Depilis*, *Phalacroctis*; when particularly on the sinciput, *Calvities*, and *Calvitium*; which Galen thinks is owing to a defect of moisture. When the bald part is smooth and winding, like the track of a serpent, it is called *ophiasis*: but the general name of all the different appearances of bald places is *AREA*; and the hair is said to fall off *areatim*, by shedding; whence in general this disease is called *area*.

Celsus says, that the *alopecia* comes at any age, but the *ophiasis* only affects infants. In childhood, it often succeeds the *tinea*, *achores*, and *favi*.

The cause is a disease of the roots of the hair. Galen says, that eating mushrooms may occasion these disorders; and that malignant or contagious diseases of various kinds may produce the same effect.

The *alopecia* spreads itself on the beard, as well as on the hairy scalp, and is irregularly formed. The *ophiasis* usually begins at the back part of the head, and creeps about the breadth of two fingers, till it hath extended its two extremities to both the ears, and sometimes to the forehead. It seems to be more malignant than the *alopecia*, since the cuticle is also corroded so far as the roots reach; the skin also changes its colour, and is pale, or darker coloured, and, if pricked, a serous blood issues out.

In the *tinea* the excoriations and exulcerations are deeper, and often the hair does not grow again.

In infants these disorders commonly go off as age advances; but in adults, the cure, especially of the *ophiasis*, is very difficult. In proportion as a redness appears readily on rubbing the part, the cure may be expected to be easy. If a leprosy is the cause, the case is more difficult of cure. The most favourable is when hairs begin to push out on the edges of the areas.

If any other disease attends, its removal will often cure the *alopecia*. If the disease is formed, the head must be shaved, then washed with lye in which are infused the abrotanum and other warm stimulants: the part must then be rubbed until the skin grows red, and gentle stimulants should be continued. See CELSUS, SENNERIUS.

AL'OSA, (from *αλισκα*, to take, because it is a ravenous fish). SHAD. *Clupea alosa* Lin. TRITTA, of ancient authors.

A sea fish, the size of a salmon, with large scales, but thin and easily taken off. This fish is in season

in the spring, but if pickled it keeps well all the year.

A'LOSAT. } See ARGENT. VIVUM.  
ALO'SOHOC. }

ALOSAN'THI, (from *αλς*, the sea, and *ανθος*, a flower). FLOWERS OF SALT.

ALPHENIC, (ALPHANAC, tender, Arab.); an Arabian word for sugar-candy, or barley-sugar. So called from its frangibility. See SACCHARUM.

A'LPHI'TA, the plural of *αλφιτον*, (from *αλφος*, white). The meal of barley that has been hulled and parched. Hippocrates uses this word for meal in general. Galen says, that *κριμνα* is coarse; *αλευρα*, fine; and *αλφιδα*, middling sort of meal.

ALPHI'TIDON, (from *αλφιδον*, meal). It is when a bone was broken into small fragments like alphi, i. e. bran; also called *caryedon*; and *catagma*, when like a broken nut.

A'LPHI'TON. Greek. A HASTY-PUDDING; in Latin, *polenta*; it is made of barley meal, moistened with water, wine, &c. commonly used by the soldiers.

A'LPHUS, *αλφθ*, (from *αφαινω*, to change,) M. A. Severinus calls it *Baras*.

This disorder is a species of that sort of white leprosy called *vitiligo*, and which is divided into the *alphus*, *melas*, and *leuce*, called also *albara*; in the *alphus* the skin is white and roughish in spots; sometimes the patches are broad, bearing the same analogy to the leuce as the scabies to the lepra; the first is superficial, chiefly affecting the skin; the second sinks deeper into the flesh: but these disorders only differ in their degrees of inveteracy. See LEPRO.

Oribasius commends lime water as a lotion in all the species; and says, that the *alphus* requires a thin lime water, the scabies a thicker or stronger, and the lepra the strongest. Aetius commends, as equally proper for the white or the black *alphus*, the following liniment:

R. Fol. ficus, sulphuris vivi et alumin rup. āā. æq. p. acet. acerrim. q. s. f. linim. cum qua inung. partes affectæ.

In all kinds of cutaneous complaints, the itch excepted, internal medicines are necessary, and generally mercurial alteratives. Their operation may be assisted by the warm bath, and decoctions of elm bark or mezeoreon. This subject will, however, be treated at length, under the article of CUTANEOUS COMPLAINTS; q. v.

See Celsus. Actuarius Method. Medend. Oribasius de Morb. Cutan. Curat. Aetius's Tetrab. iv. Germ. cap. i. 132. Willan on Diseases of the Skin.

A'LPHINI, Bals. BALM OF GILEAD. See BALSAMUM.

ALPIN. ÆGYPT. The abbreviation for Prosperus *Alpinus* de Plantis Ægypti.

ALP. EXOT. The abbreviation for Prosperus *Alpinus* de Plantis Exoticis.

ALP. PL. ÆG. The same author de Plantis Ægypti.

ALSADAF, the UNGUIS ODORATUS; and the MUREX, of the shell of which it was supposed to be a part.

ALSCHNEFU, a term for WORMWOOD.

ALSIMBEL and SIMBALA, the SPIKENARD of India, from the number of its ears or "spikes."

A'LSINE, (from *αλς*, a grove, because it delights in shade). It is also called *morsus gallinæ*. centunculus;

in English, CHICKWEED and MOUSE-EAR; *cerastium vulgatum* Lin. 627; called in English from its leaves resembling the ears of mice.

It is cooling, but scarcely ever employed as a medicine. It is used to promote an appetite in linnets and Canary birds. The name also of a species of saxifraga, or the whidow grass. See PARONYCHIA.

ALSIRACO'STUM, (ALSIRAKA, *evacuation*. Arab). The name of a compound purging medicine in Messue; called also *siracostum*.

ALSURE'NGIUM. See HERMODACTYLUS.

ALT. The abbreviation for ALTER and ALTDORF.

ALTAFOR. See CAMPHORA.

ALTERA'NTIA, (from *altero*, to change). ALTERATIVES. Medicines of this kind claimed formerly a considerable share of the physician's attention, when acrimony was the most common reputed cause of diseases. This subject will be considered at length under the title of PATHOLOGY. It is sufficient at present to remark, that many of the supposed acrimonies have no existence, and the class of *alteratives* is consequently limited. We have, however, still the inspissants and attenuants, which, though they do not permanently affect the state of blood, yet change that of the excretory fluids; and so far, in a remote view, may be styled alterants. These are to be considered under their proper heads. Alteratives, in the present more scientific views of pathology and therapeutics, are those medicines supposed to correct the acrimony which appears in eruptions on the skin, formerly called the scorbutic acrimony. These are almost exclusively mercurials, assisted by the medicines just spoken of under the article ALPHUS. They do not act by any chemical affinity on the mass of fluids, but by their power of gradually increasing the secretion from the skin; for we shall show, that cutaneous complaints are seldom owing to any increased acrimony, but sometimes to an obstructed cutaneous discharge; and, at others, to the excessive rapidity of this evacuation. The only instance of a real change in the circulating fluids, is in sea scurvy, and in high putrid fevers. The latter admit not of alteratives; and in the sea scurvy, the only useful medicine of this kind is a vegetable diet.

*Alteratives* have been given with other views, and seem occasionally to have some effect. We allude to the use of sea water in scrofula, to burnt sponge and mercurials in the same disease. In scrofula, there is evidently a want of irritability; and we may suspect a want also of a due proportion of neutral salts, which give fluidity to gluten, when dissolved in the serosity, forming the serum. This defect may occasion the stagnation of fluids in the conglobate glands, and we should be more confident in this explanation, were the contents of these glands gluten. The saline remedies, above mentioned, are undoubtedly useful, and probably act as attenuants; the mercurials are alterants by increasing the action of the vessels, deficient from the want of irritability. Emmenagogues and tonics are sometimes also considered as alterants, but with little accuracy. In fact, if there is any real medicine of this kind, it is mercury used in venereal complaints; to which we cannot deny some alterative power. It is proper, however, in this early part of our work, to declare our opinion, that it chiefly acts by exciting and supporting the evacuation from the skin.

ALTERCANGENON. ALTERCUM. See HY-OSCIAMUS NIGER.

ALTERNUS; ALTERNATE. Used in medicine when two different remedies are employed in turn.

ALTEY PLU'MBI. Most probably the CERUSSA ACETATA.

ALTHÆ'A, (from *αλθεω*, to heal,) called also *bismalva*, *hibiscus*, *malvaviscus*, *bolus Judaica*, *anadendromalache*, *anadendron*, *aristalthea*; in English, MARSH-MALLOW. It is the *althea officinalis* Lin. Sp. Pl. 966, and Willdenow, G. 1289, Sp. 1. Natural Order, *Columnaceæ*.

All the parts of this plant abound with a mucilaginous matter, with little odour or taste. The dry roots, if boiled in water, give out near half their weight of gummy matter, which, in evaporating, forms a flavourless yellowish mucilage; the leaves afford nearly one-fourth, the flowers and seeds still less.

All its virtues depend on its mucilage, and consequently its demulcent and emollient qualities, where the membranes become abraded, or the mucus thin and acrid: it moderates tickling coughs, gives relief in hoarseness, erosions of the stomach and intestines, dysentery, difficulty and heat of urine, and nephritic complaints: two or three ounces of the fresh roots, or one ounce of the dry, may be boiled in a sufficient quantity of water to a quart, to which one ounce of gum arabic may be added, and one dram of nitre: a little of the juice of liquorice renders it more palatable. From long boiling, it acquires a bitterish taste; and when ordered in a decoction of the woods, it must be put in some time after the other ingredients.

The London College has introduced a syrup of *althea*; and more refined practice a very pleasing and more efficacious form—a paste made from its powder, viz. pate de guimauve.

The custom of sitting over an infusion of marshmallow leaves for curing the piles, is useless, for nothing of the mucilage arises with the watery vapours.

Externally it is employed in emollient poultices; and in the foreign Pharmacopœias it is an ingredient in, and gives a name to, an ointment.

The great comfrey root is preferable in all the cases wherein the *althea* is used.

ALTHA'NACA, or ALTHANACHA. See AURIFIGMENTUM.

ALTHEBE'GIUM. An Arabian name for a swelling observed in cachectic and leucophlegmatic habits, and such as is seen under the eye-lids of those who sleep too much.

ALTHIT. (HALTHITH, Arab). See LASERPITUM.

ALTIMAR. BURNT COPPER. See ÆS USTUM.

ALTINGAT. RUST OF COPPER, OF FLOWERS OF COPPER. See ÆRIS FLOS.

ALTINURA'UM. See VITRIOLUM.

ALUACH, or ALUECH. See STANNUM.

ALUD. (ALHUB, Arab). See AGALLOCHUM.

ALUDE'EL. (Arab. *vessel*). A CHEMICAL SUBLIMING VESSEL; called also *Cementarium*. Many are to be employed at once; the matter to be sublimed is put into a body or pot, the upper part is fitted into the *aludel*, and this *aludel* into another, &c.: to the top *aludel* a head or alembic is fixed to receive the sublimed matter.

ALUM, (from *αλυαομαι*, to wander; from its creeping roots). See CONSOLIDA.

ALUMBAIR. BUTTER. See ADEPS.

ALUMBOTI. CALCINED LEAD. See MINIUM, under PLUMBUM.

ALUMEN (ALUM, Arab.). The Greeks called it *ερυπτηρια*, *Assos*, *azub*, *Ascb*; and when extremely hard, as iron, *Elanula*. It is an earthy salt, consisting, in a great measure, of the vitriolic acid and a pure clay, changing the purple juices of vegetables into a red colour; and extracted from substances usually called alum ores, which either are, or probably were, originally composed of clay and sulphur.

The present practice employs only the last two of the following species; but all the four have been in use.

1. ALUMEN PLUMOSUM OFFICINARUM. EARTH FLAX.

It is entirely rejected from medicine, being more dangerous than useful. See AMIANTHUS.

2. ALUMEN PLUMOSUM VE' RUM, also called *scissile*, *jamenum*, *plumcum*, *trichites*. The PLUMOSE, FEATHERED, or HAIRY ALUM.

It sometimes shoots upon the surface of those minerals that afford the factitious *alum*, and is also found on other bodies in the form of fibrous efflorescences. It seems to be the native *alum* of the ancients; and is formed by the evaporation of water that hath passed over beds of *alum* stone.

3. ALUMEN COMMUNE, COMMON ALUM; also called *alumen crystallinum*, *rupeum*, *factitium*. FACTITIOUS or ROCK ALUM; ENGLISH ALUM.

4. ALUMEN ROMANUM, ROMAN ALUM; also called *alumen rubrum*, *rutilum*, *rochi Gallis*. ROCK, RED, or ROCH ALUM, by the French.

These two latter agree in their general qualities. The greatest quantities of them are artificially produced from different minerals, such as a blue slate, which is found about Scarborough in Yorkshire, Preston in Lancashire; and a whitish stone at Tolfa near Rome: these stones are calcined and exposed to the air. They thus absorb oxygen and become an acid salt; for in all *alum* the acid is in excess, which occasions its changing the blue colour of vegetables to a red. In the *alum* of commerce, or rather in the form offered to us as a medicine, there is a proportion of potash or ammonia. Each of these is supplied in its preparation; the latter from urine; and the former, at least, is essential to its crystallisation, but the excess of either, above the other, does not seem to injure its medicinal properties. It generally contains, according to Vauquelin, 49 parts in 100 of sulphate of alumine; 7 of sulphate of potash; and 44 of water. This proportion of water occasions by heat the watery fusion; but, in a higher temperature, the water, and at last the acid, escape. Its crystals are regular octaedrons, representing an indented column, whose sides are equilateral triangles. It is soluble in about 16 times its weight of cold water, in a temperate heat, and in about 3-fourths, at the boiling point. Its specific gravity is 1.71. As the acid is in excess, its proper name is *super sulphas aluminæ et potassæ*. When more completely saturated with the aluminous earth, it crystallises in cubes, and is called cubic *alum*; but it then loses its medicinal powers.

The English or common *alum* is colourless, and commonly in large masses, into which it is cast by

melting the crystals after the *alum* is perfectly made, and then pouring the fused matter into vessels, whose cavities give the forms it appears in. The Roman *alum* is of a reddish colour, and in small crystallised masses; but its chief difference from the English is in its being less styptic, and less nauseous. The name of *roch*, or rock *alum*, is applied to our *alum*, on account of the hardness and size of the masses; but foreigners apply it to the Roman, on account of the hard stone, or rock, from which it is extracted.

*Alum* hath a peculiarly sharp, rough, astringent taste; it melts over a gentle fire, sending up in a vapour nearly one-third of its weight, and becomes a light, white, spongy substance, called ALUMEN USTUM, BURN'T ALUM; it is the only salt that, with other animal ingredients, or vegetable matters, will make the black pyrophorus, which is owing almost exclusively to its potash. With an infusion of galls it becomes turbid and whitish. Upon adding a fixed alkaline salt to a dissolution of *alum*, its earth is precipitated, and its acid uniting with the alkali forms a tartarum vitriolatum, sulphas potassæ.

It is used by dyers to strike, fix, clear, and brighten their colours: it serves as the *mordant* to all colours; and by dipping paper in it, ink is prevented from spreading: vintners fine their liquors with *alum*; fishermen use it to dry codfish; it preserves animal substances from putrefaction, and wood from burning; it is used in the manufacture of leather; by calico printers, engravers, and soap-boilers; and bakers mix it with flour to make their bread white and compact.

Medicinally, it is employed as a powerful astringent; as such it is prescribed to preserve the gums, to restrain uterine hæmorrhages, and check the fluor albus; but though in these diseases it is highly commended, it is rarely, and with great caution, to be admitted in dysenteries, particularly in the beginning. Though celebrated as an astringent in some cases, it is no less extolled in the colic and other painful disorders of the bowels, attended with obstinate constipation. See Percival's Essays, vol. ii. The doses in these cases are from five to twenty grains, and may be repeated every four, eight, or twelve hours; and when duly persisted in, prove gently laxative, mitigate the pain, abate flatulence, restore the appetite, and strengthen the organs of digestion. *Alum* is powerfully tonic, and is supposed to contribute to the relief of pain in the intestines, by blunting the morbid sensibility of their nerves. In robust habits, after due bleeding and purging, it cures agues; and Dr. Cullen thinks it ought to be employed with other astringents in diarrhæas. In active hæmorrhages it is not useful, though a powerful medicine in those which are passive. It should be given in small doses, and gradually increased. It has been tried in the diabetes without success: joined with nutmeg it has been more successful in intermittents, given in a large dose, an hour, or a little longer, before the approach of the paroxysm. In gargles, in relaxations of the uvula, divested of acute inflammation, it has been used advantageously; as well as in every state of the cyanche tonsilaris. It is also preferable to white vitriol, or acetated cerusse, in the ophthalmia membranarum; from two to five grains are dissolved in an ounce of water, for this purpose. Cullen's Mat. Med.

The Roman *alum* is counterfeited with common *alum*

coloured; but break it, and the counterfeit will be found pale within, while the true is of a deeper red.

Its pharmaceutical preparations are well known. The aqua aluminosa contains a drachm of the salt to six ounces of water. In the compound alum water, as much vitriolated zinc is added: in many hospitals, however, the proportions are greatly increased. The alum curd consists of the white of two or three eggs shaken with a little alum, recommended for chronic inflammation of the eyes; and alum whey is made by adding two drachms of alum to a pint of cow's milk. The purification of alum by chalk, as directed by the London College, seems to injure its virtues. See STYPTICUS HELVETII PULVIS.

In extemporaneous prescription, the greatest caution is requisite. Almost all the salts destroy the union of its ingredients, but fortunately selenite is not of that number; so that hard water may be employed in its solution. Yet carbonat, nitrat, and muriat of lime, will decompose it. Mild ammonia and magnesia with its various neutrals, and all salts whose bases are barytes, potash, soda, and perhaps strontian, will have the same effect. It is decomposed also by the gallic acid; probably by tannin; certainly by the gummy resin kino; by various colouring matters; by different animal and vegetable substances. A similar effect is produced by eau de luce, by the different mercurial salts, and by the sugar of lead.

ALUMEN CA'TINUM. A name of potash. See CLAVELLATI CINERES.

ALUMEN GLACIALE. When transparent like ice.

ALUMEN PLUMOSUM. } See ALUMEN.

ALUMEN USTUM. }

ALUMINO'SÆ, Aq. Waters impregnated with the particles of alum. What gives efficacy to these waters is said to be an acid aluminous mineral salt, dissolving a slight mixture of iron, and united with other materials. They are supposed to be deobstruent, and beneficial to hypochondriac and cachectic patients; and not astringent, as the idea of their being solely impregnated with alum would induce us to conclude.

ALU'NSEL. A DROP. See GUTTA.

A'LUS.

A'LUS GA'LLICA. } See CONSOLIDA.

AL'USAR. See MANNA.

ALVEA'RIMUM, (from *alveare*, a bee-hive). The bottom of the concha or hollow of the external ear; it terminates in the meatus auditorius. It is in this cavity where the ear-wax is principally lodged.

ALVEOL'ARIS PROCES'SUS. So called from the likeness to an honey comb. See MAXILLARIA SUPERIORA OSSA.

ALVE'OLI, (a dim. of *alveus*, a channel,) called also *bostrion*, or *bothrion*; *frena*, *mortariolum*. The sockets in the jaws in which the teeth are set; they are lined with a very sensible membrane, which also incloses the roots of the teeth. There are usually sixteen of these *alveoli*, or sockets, in each jaw.

A'LVEUS, a channel. Medicinally, it is applied to many tubes or canals through which some fluid flows, particularly to ducts which convey the chyle from its receptacle to the subclavian vein.

ALVIDU'CA, (from *alvus*, the belly, and *duco*, to draw). Medicines which purge. See PURGANTIA.

A'LVI'FLU'XUS, (from *alvus*, and *fluo*, to flow). See DIARRHŒA.

A'LVUS, (from *alveus*, a channel). The BELLY. Celsus uses this word for the belly, relative to the intestinal discharge, as Hippocrates and others use the words *κοιλια*, or *κοιλιν*. See also ABDOMEN.

A'LYCE, (from *αλωω*, to be anxious). See ALYSMOS.

ALY'PIA, ALY'PIAS, A'LYPUM, (from a neg. and *λυπη*, pain). The HERB TERRIBLE. It is also called WHITE TURBITH. *Prutex terribilis*, *empetrum*, *thymelea*, and *globularia fruticosa*. *Globularia alypum* Lin. Sp. Pl. 139. Not used at present in medicine.

ALY'SMOS, A'LYCE, (from *αλωω*, to be uneasy, or anxious). ANXIETAS, ANXIETY. Hippocrates uses it to express that restless uneasiness that is attendant on acute diseases. Duretus distinguishes between the *αλυσμος ανεμετος* and the *αλυσμος ναυτιδης*. The first is caused by an oppression of the vital powers; the latter by sickness in the stomach; but of this last *alysmos*, called also *diaphorema* and *aphoria*, there are reckoned four sorts.

The 1st and 2d of which are without, the 3d and 4th with fever; and occasioned, 1st, By something uneasy in the stomach, producing an irregular contraction of the heart, and a difficult passage of the blood through the lungs. Uneasiness of the stomach by sympathy, as from a stone in the kidneys, &c. produces this disorder.

2d, By vapours or spasms in the stomach, or other viscera; as in the cholera morbus, hysteria, &c.

3d, From a difficulty in the passage of the blood through the lungs, which may be from a spasmodic stricture in the smaller vessels, in which case the blood is confined to the larger. In inflammatory fevers, this symptom is attended with a low pulse, oppression in the breast, and difficult breathing.

4th, From a stricture of the vena portæ, which prevents a free circulation of the blood in the lower belly. In this case there is great weight and oppression of the hypochondria.

ALYS'SUM, MADWORT, (from *a*, for *an*ti, and *λυσσα*, that madness which the mad dog occasions by his bite). It is the *marrubium alysson* Lin. Sp. Pl. 815, and has been considered as a diaphoretic.

ALYS'SUM GALENI. The MARRUBIUM.

ALYS'SUM PLINII. The MOLLUGO.

ALYS'SUM VERTICILLATUM. See MARRUBIUM VERTICILLATUM.

ALZE'MAFOR. See CINNABARIS.

ALZI'LAT. The name of a weight of three grains.

ALZO'FAR. BURNT COPPER. See ÆUS USTUM.

ALZUM, ALDUM, and ALRUM. The name of the tree that produces gum bdellium in some ancient authors.

A'MA, A'ME, or A'MES, (Syriac). A sort of small cake. Aretæus uses this word to compare the quantity of hellebore for a dose.

AMA'LGAMA, (from *αμα*, simul, and *γασιν*, nubile, vel *μαλαττειν*, mollire). Its chemical character is

A. A. A. In chemistry it is a soft paste, produced by mixing mercury with a metal.

All metals may be amalgamated with mercury, except iron; but gold amalgamates the most readily; then silver, lead, and tin in order; copper with difficulty.

With amalgamated gold, silver and other metals are gilt; but this subject does not belong to medicine.

A'MALT. The abbreviation for *amalthæum*.

AMAME'LIS, (from *αμια* and *μηλια*, an *apple*). The *amamelis* of Hippocrates is supposed to be the same with the *epimelis* of Dioscorides, which is the small bastard medlar.

There is another medlar in Italy, called the *epimelis*, also *setanium*. See *MESPILUS*.

AMANI'TA, (from *a*, priv. and *μανια*, *madness*). The eatable mushroom, not poisonous. Their tribe is therefore called *Aminita*, *Fungi*, and *Tubera*. The fungous productions called MUSHROOMS, TRUFFLES, &c.

Among the ancients these are noticed only by Oribasius, Paulus Ægineta, and N. Myrepsus.

Among the moderns, they have only within about fifty years claimed particular attention, and it was long doubted whether they were really vegetables, or only the nidus of numerous animalcules. It is needless, on a point not connected with medicine, to enlarge by adducing the history of opinions on this subject. M. Bulliard has, at last, proved them to be really organised bodies of the vegetable kingdom. That they are propagated by seed is highly probable; but what Bulliard seems to have mistaken for the seed, Gærtner and Mirbel have shown, with some success, to be buds. Parmentier joins in the same opinion. What has been described as the male and female organs are consequently parts whose uses have not yet been discovered. Mushrooms, however, resemble plants in this respect, that their nutrition is derived from fluids drawn in by vessels; and the more solid kinds, resembling cork, show the annual deposition of concentric coats: in those still more solid, the resemblance to plants is stronger; while, in the transitory productions of short duration, the fluids, instead of being conveyed by vessels, seem to pass through a cellular substance by capillary attraction. From analysis they appear, as we have said, of an animal nature; and, under water, give out hydrogenous, azotic, and carbonic acid gas; by distillation, ammonia.

Parmentier considers mushrooms only as condiments. He thinks them incapable of being assimilated, and without any nutritious particles. In this, however, he is evidently mistaken; since tannin precipitates an albuminous substance from the water in which some of the species have been infused. A few only of the mushrooms are eatable: some are insipid, and some poisonous. Of the eatable ones, however, the flavour is delicious; and, as it is volatile, mushrooms are employed in Piedmont to give a flavour to some liquors. The poison of the injurious kinds is of a sedative nature, resembling, as we shall find, in its effects, hemlock. Some authors have therefore advised substituting a similar flavour from other vegetable substances. We know that an Indian bean, a species of *dolichos*, will, in a great degree, supply it as in the soy. The bottoms

of artichokes resemble it very nearly; and, by some management, even celery is not very unlike.

The only sorts in general use are the MUSHROOM, the TRUFFLE, and the MORILLE.

The true mushrooms, *agaricus campestris* Lin. are known by their external whiteness, and by being of a pale red within when young, and of a deeper red, or dark, when older; they are, at their first appearance, of a round figure, and not much larger than a small nut; after they have a little unfolded their membranes, they appear red, full, and close; on the top is a disagreeable softness, equal and white; the matter within is very white, with short and thick stalks. They grow in fertile ground, and should be gathered for eating as soon after springing up as possible, for they then contain an oily and a saline part; and if they stay long before they are gathered, their salts become more active and hurtful.

Another species of agaric, which now begins to attract the attention of the luxurious, is the *a. orcades* of Bolton; that kind which produces the circular appearances in fields, styled fairy rings. Its substance is tough, and consequently it is used only to make catchup, or in powder. It greatly resembles another species, the *mucron* of the French, employed in ragouts. There are several other species of agaric used, particularly a large one found in Cornwall, near the coast, but we need not enlarge further on the subject.

The TRUFFLE belongs to that family of fungi whose seeds are internal. The *tuber cibarium* of Bulliard is, we believe, the only species generally eaten; though the musk, the white, the American truffle, and some others, specifically distinct, are mentioned among delicacies. It is firm and fleshy, and its surface covered with prismatic tubercles; when at its full growth blackish, with white veins. It is buried about four or five inches deep in the earth, and discovered by hogs, or dogs trained for the purpose, as these animals are very fond of this fungus. De Bosch, who has written at some length on the truffles of Piedmont, informs us, that numerous tipulæ may be found over the place where truffles abound; and the larvæ of little flies, with red eyes, which likewise feed on truffles, lead to the spot. With respect to truffles, Bulliard gives up his seminal system, and calls them viviparous; as he finds the young fungus attached to the parent by a cord resembling the umbilical. As a food, truffles are stimulant and difficult of digestion. M. Bouillon la Grange has engaged at great length in their analysis; of which we find an abstract in some late volumes of the Critical Review. It differs little from the chemical analysis of other fungi; but we may remark, that truffles contain magnesia and some portion of albuminous matter. From the truffle the most odoriferous and pleasing liqueur is prepared.

The MORILLE is a mushroom whose stalk is hollow, and whose head is irregularly indented and wrinkled. It belongs to the family whose seeds are on the superior part of the mushroom, or, more strictly, which adhere to the surface of the cavities of the hat. It is of the genus *phallus*, and two sections have been distinguished; of which the *p. esculentus* and *impudicus* are examples. Ventenat, however, has shewn that this distinction is not strictly accurate, (Mem. de l'Institut, vol. i.). Yet on the whole, in a general review, it may

be adopted. The morille, in its early stages, is of a greyish brown, but becomes afterwards black. In the first period it is preferred on account of its odour and flavour; for at last it becomes insipid. It should be cut off, not torn up, because the water, which rises in the cellular substance, conveys some earth with it; and, if collected while the dew is on the ground, it soon becomes mouldy. When strung on cord, they will keep in a good state a long time, but should be moistened with warm water before they are used. Some other species of phallus are esculent; but it is useless to enlarge on them. If we recollect rightly, 13 species are described by Ventenat in the Memoirs of the Institute, and three other American species have been since added.

To various causes are attributed the disagreeable effects which some persons experience after eating them. The deleterious effects of these vegetables have been attributed to little worms, to their being too old, too long kept, &c. We cannot deny the effect of the worms; but as they are seldom, if ever, observed in the esculent kind, it is not probable that any injury can arise from them. The other causes are certainly inadmissible; since mushrooms are generally eaten at every period of their growth with impunity. We suspect that the mischief rather arises from mistaking the species, which, from the similarity of the poisonous to the esculent kinds, is easy. Bosch, however, informs us, that steeping the mushroom in water, or, what is preferable, vinegar, for a short time, will take away every probable inconvenience. The poison of the deleterious kinds, which differ in their chemical analysis from the others only in being more watery, is not of a volatile nature, and does not rise in distillation. Mushrooms raised from seed in hot-beds are never, we believe, poisonous. They are said to contain a larger proportion of oil; but they are less rapid, and more firm in their substance. It is the *agaricus esculentus*, or *campestris* of Linnæus, the *amanita esculenta* of La Marck, that submits most readily to this artificial mode of propagation.

When offended by eating them, some of the following symptoms are produced; a qualmishness first affects the patient, which increases to a considerable degree of sickness, swelling of the stomach or of the belly, restlessness, giddiness, a palpitation of the heart, heart-burn, colic, hiccough, diarrhoea, accompanied with a tenesmus, flushing heat in the skin, with more or less of redness there, and swelling in the face, and sometimes a sensation all over the body, which resembles what is felt from a general swelling; the patient stares in an unusual manner, all objects appear different from what they did before; a difficulty of breathing comes on, and the mind is strangely confused; delirium, trembling, watching, fainting, cold sweats, apoplexies, and convulsions, have followed the eating of this sort of fungus.

For the relief of persons under these circumstances, as speedily as possible, from gr. x. to ℥ i. of white vitriol, dissolved in a draught of warm water, should be given; and if the sickness is still urgent, the same quantity repeated two or three times, that the stomach may be well emptied. After this a large spoonful of vinegar in a glass of water should be frequently taken. The poison is not of the acrid kind, so that fat broths and oily medicines are useless. After evacuations up-

wards, a passage downwards by purgatives or clysters must be procured. After due evacuations of each kind, and besides the vinegar, cyder and perry, that are brisk and sparkling, may be now and then given. If any paralytic symptoms appear, sinapisms or blisters are necessary.

AMARA. (MARAR, to grow bitter. Heb.) BITTERS. Bitterness is a simple perception which cannot be defined, but must be referred to experience. What is the nature of the substances possessed of it, in a chemical view, we cannot determine, and consequently cannot explain.

The bitter is so often united with the astringent, the tonic, or the aromatic principle, that it has not been usual, in therapeutical authors, to distinguish the effects of the pure bitter. In this place, it must be considered as unconnected with either; and examples of a truly pure bitter we may find in the camomile flowers, the quassia, the gentian, and the columba. These, it is said, are tonic: we can scarcely think so. They are antiseptic, and most probably antacid; and from these qualities they correct the morbid state of the fluids in the stomach, thus giving strength by destroying the causes of weakness. The bile of animals appears to be a pure bitter; yet it is probably not so, since it occasions in the stomach sickness and faintness.

Dr. Cullen seems to suspect that bitters are narcotic; but his chief argument arises from their effects in gout, when, in the form of the duke of Portland's powder, they have been long continued. Various collateral circumstances have, however, convinced us that bitters should not be long continued without some intermission.

Bitters have been used as resolvents; a term not strictly defined, but intended to convey the idea of their resolving obstructions of the liver or other viscera. When joined with fixed alkalis or neutral salts, they seem to have this effect; and, in this union, they are also febrifuge. They formed the mild febrifuge of Boerhaave, who, with little chemical accuracy, styled them saponaceous. In this form, at least, pure bitters are not injurious to the robust or inflammatory habits; and we suspect that without the union of the salts they would not be hurtful in such constitutions; yet they are seldom, if ever, indicated in persons of this description, and the disquisition would tend to no useful purpose. Bitters, we have said, are stomachic; they are also slightly laxative; but we have never found them, as some authors have alleged, diaphoretic.

There is another class of bitters unconnected with those above mentioned; viz. the narcotic. Of this kind we have examples in the hop, the cocculus Indicus, the lactuca virosa, opium, perhaps the bitter of the myrrh, and of the Iceland liverwort. These are never employed, except in very small doses, for the purposes before mentioned. They will be more fully considered under their proper heads. We mention them in this place merely to connect the subjects, and to suggest a suspicion that these two kinds are very nearly related; to enforce also a due attention to the supposed narcotic power of common bitters. With this perhaps their anthelmintic power may be connected; but though the greater number of anthelmintics are bitter, yet it is in a very slight degree, if at all, a property of bitters in general. An additional proof of the connexion of the narcotic with other bitters, is their febrifuge power.

The faba St. Ignatii, a bitter of the narcotic class, is highly celebrated for the cure of intermittents; and a considerable febrifuge power seems to reside in the greater number.

Bitters yield their virtues both to watery and spirituous menstrua: they yield very little of their taste by distillation, either to water or spirit; nay, the bitterness is so tenaciously detained, as to be improved in many extracts. Cold water extracts the pure bitter without any mixture of unpleasant roughness. Even the cold infusion of the carduus benedictus is pleasant.

AMA'RA DU'LCIS. See SOLANUM LIGNOSUM.

AMA'RA INDICA. See MEMORDICA.

AMA'RA, Tinct.

AMA'RUM SIMPLEX, Infus. } See GENTIANA.

AMARA'CUS, (from *a*, non, and *μαραίνω*, to decay, because it keeps its virtues a long time,) SAMPSUCHUS. See MAJORANA MAJORI FOLIO.

AMARA'NTHUS, (from the same). LUTÆ'US. GOLDBLOCKS. See ELICHRYSUM.

AMARE'LLA, (from *amara*, bitter). See POLYGALA. A name also of Gentian.

AMA'RUS, DU'LCIS ORIENTA'LIS. See COSTUS.

AMA'RUS SAL. See CATHARTICUS SAL.

AMATO'RIA FEBRIS, (from *amo*, to love). See CHLOROSIS. In Vogel's Nosology, *amatoria* is defined to be a fever of a few hours' continuance, beginning with a great degree of coldness, and arising from expectation of marriage.

AMATO'RIA VENI'FI'CIA, (from *amo*, and *venificium*, witchcraft). See PHILTRON.

AMATO'RIOUS. The *obliquus superior*, or *trochlearis*, and the *obliquus inferior oculi*, are thus named, as ogling is performed by these muscles.

AMATZQUI'TL, (Indian): vel UNEDO PAPYRACEA. *Arbutus unedo* Lin. Sp. Pl. 566.

The wood is of a light texture, the leaves resemble those of the lemon tree, but are hairy and more pointed; the fruits are large as Pontic nuts, divided into white grains of the same shape and nature with those of a fig. It is met with in warm countries only. A decoction of the bark of its root is commended in fevers.

AMAUROSIS, (from *μαυρος*, obscure). It is a DECAV or LOSS OF SIGHT, when no fault is observed in the eye, except that the pupil is somewhat enlarged and motionless. This disorder is styled a *gutta serena*; *cataracta nigra*; *affuscatio*; *cacitas minor*; *mydriasis*. Some call it AMBLYOPEIA; q. v.

M. de St. Yves distinguishes this disease into the perfect and imperfect kinds. The perfect consists in total blindness; in the imperfect, there is at least a power of distinguishing light from darkness. There is a species which comes on instantaneously, continues for some hours, or days, returning often periodically in hysteria, &c. In another species, the pupil is always contracted, whether the unaffected eye is open or shut. In infants, the pupil is sometimes, though seldom, of its natural size, but no movement is observed in it, however exposed to the light. The nyctyalops is supposed to be a species of this complaint.

The causes are, a palsy in the retina, a tumour, or a plethora in the adjacent vessels; a translation of either a venereal or other poison. Suppressed periodical evacuations, vapours, hysteric and other nervous symptoms, sedative poisons, external injuries, or whatever

intercepts the nervous influence in the eye, may produce this disease. In the middle of the optic nerve runs that branch of the carotid artery which enters into the eye; this artery, when distended, may press the nerve; render it paralytic, and cause the periodical species.

Dr. Cullen ranks this genus of disease in the class *locales* and order *dysæsthesiæ*; and enumerates the species from the following causes, viz. compression, debility and its causes, spasm, and the applications or the swallowing of poisons. The application of the beladonna produces this disease.

On dissection, the optic nerve is sometimes found flaccid, and by far too small; in others it is compressed by extravasated blood, by a tumour, or by a turgescency of the artery which passes through it.

The phlegmatic, cachectic, aged, those with weak nerves, or that have been subjected to severities or excesses, and persons labouring under irregular or suppressed periodical discharges, are the principal subjects of this disorder.

The signs that indicate the presence of amaurosis are generally the blackness of the pupil of the eye, its size being larger or less than usual, and its not contracting nor dilating when exposed to a great degree of light. Its approach is generally attended with pain in the head; and as the pain decreases this disorder increases, though sometimes an absolute blindness comes on without any previous complaint. When it comes on without pain, and one eye only is diseased, no defect is discovered until the sound eye is closed; then the pupil of the diseased eye dilates, though exposed to a strong light; and when the other eye is opened it contracts to its natural size again. When it gradually comes on also, little specks appear on an object, or small flies seem to float before the eye, in the language of pathologists, *musca volitantes*. In infants the pupil is sometimes of a natural size, though it hath no movement; and thus they continue during many months, before they can see. When pregnancy, suppressed periodical discharges, nervous disorders, or vapours, are the cause, a headache, vertigo, drowsiness, noise in the ears, &c. often usher in this disorder: in these cases it frequently returns, but soon spontaneously passes away.

The prognostics are generally unfavourable: if this blindness succeeds a fever, comes on in the aged or very infirm, a cure is not to be expected; if one eye fails, the other soon follows; but if the case is slight, the habit of body robust, if it happens after the measles or the small-pox, or about the age of puberty, it is sometimes cured.

The treatment of amaurosis is not often successful. It is easy to draw indications from the causes; but when it proceeds from plethora, sanguine or serous, bleeding or purgatives have equally failed. In this exquisitely tender organ, palsy is apparently induced before the evacuations can relieve the oppression. Of internal remedies, valerian, castor, and the whole tribe of antispasmodics, have been most successful; but these should probably be confined to cases where it is connected with hysteria, and in these the disease often spontaneously disappears. The internal use of mercury has been recommended, but we have never found it efficacious. Active emetics have often succeeded, apparently from the general shock given to the system; and we

know not from what cause the vitriolated mercury (turbith mineral) seems most salutary. If the resolution or the constitution can bear these severe shocks twice a week, amaurosis may frequently be removed. Setons and blisters to the neck do no service; but when the blisters have been applied to the temples they seem to have been occasionally useful. Sternutatories have been employed, but, in our hands, with little success. The best is the turbith mineral, with about ten times the quantity of any mild powder. Electrical sparks drawn from the eye twice a day have proved highly beneficial; and the Galvanic influence, if rescued from the hands of quacks, promises considerable relief.

See Heister's Surgery, Hoffman's Med. Rat. Syst. St. Yves on the Diseases of the Eyes. Mead's Cautions and Precepts. London Med. Journal, ii. 10. Wallis's Sauvages' Nosology of the Eyes, p. 151, &c. 271.

AMAUROSIS à SY'NCHYSI. } See CALIGO PUPILLÆ.  
AMAUROSIS à MY'OSI. }

AMAZO'NUM PASTI'LLUS, usually given to chlorotic maids. THE AMAZONS' TROCH. These troches were formerly prepared of the seeds of smallage and anise, the tops of worm-wood, of myrrh, pepper, &c.

A'MBA. (Indian). See MANGA.

AMBAI'BA. (Indian). It is a tall tree growing in Brasil, with but few branches at the top; the trunk is hollow its whole length, except that its cavity is divided by a transverse membrane at every two or three inches distance; in the middle of which is a small hole. The root is very hard, even so as, by a gentle friction, to afford fire enough to burn cotton. The buds afford a juice that is cooling, if mixed with gruel. This the Indians call tapioca. See Raii Hist. Plant. It is the *cecropia peltata* Lf. Sp. Pl. 1449. A tree which produces a milky juice similar to the caoutchouc.

A'MBALAM, an Indian tree; also called *manga*. It resembles very nearly the cat-abolam. The root, used as a pessary, is said to promote the menses; the bark and the juices are used in dysenteries; and a decoction of the wood is commended in gonorrhœa. See Raii Hist. Plant. It is the *mangifera Indica* Lin. Sp. Pl. 290, the tree which produces the mango.

A'MBAR. See AMBRA.

A'MBARUM. (ABARA, Arabic). AMBERGRISE. See AMBRA CINERACEA.

AMBARVA'LLIS, FLOS, (from the Latin word *ambire*). See POLYGALA.

A'MBE,

A'MBI, } (from *αμβη*, a LIP, EDGE, OR BORDER).

An instrument used in dislocations of the humerus, called Hippocrates' *ambe*, from his having noticed it. Galen explains the word *ambe* by *αφρωδης επαναστασις*, an eminence like a border; and says, that the whole machine takes that name because its extremity runs out with an edge, like the lip or brim of a pot, towards the interior cavity.

When the head of the humerus rests in the axilla, this instrument is sometimes of service, but in no other case: and even here it is rarely used; for when gentle methods fail, violence seldom succeeds.

A'MBEGU. See MYROBALANI EMBLICI.

A'MBIA MO'NARD. A yellow liquid petroleum, VOL. I.

smelling like tacamahaca. - It flows from a fountain near the Indian Sea; and is used for the cure of itch.

AMBIDE'XTER. AMPHIDEXIOS. (From *αμφι*, both, and *δεξια*, the right hand). A man equally active with both hands.

AMBLO'SIS, (from *αμβλω*, to cause abortion). See ABORTUS.

AMBLO'TICA, (from the same). Medicines which occasion abortion.

AMBLYO'GMOS, AMBLYOSMOS, (from *αμβλως*, dull). DIMNESS OF SIGHT.

Hippocrates observes, that dimness of sight and coruscations of light are among the symptoms of an approaching hæmorrhagë, in continual fevers and genuine tertians. Galen improperly explains this word by *abortus*.

AMBLYO'PIA, (from *αμβλως*, dull, and *οψ*, the eye). *Visus debilis*. This is a debility of sight, absolute or relative, without any apparent opacity of the cornea or interior part of the eye. See AMAUROSIS.

Hippocrates means by this word, in his Aph. xxxi. sect. 3. the dimness of sight to which old people are subject.

Paulus and Actuarius use it to express a *gutta serena*, and the latter considers it as arising from a defect of the nervous influence. De Meth. Med. lib. ii. cap. 7.

The *amblyopia* comprehends, 1st, *Myopia*, or short-sightedness: 2dly, *Presbytia*, or seeing only at a great distance: 3dly and 4thly, *Amblyopia tenebrarum* and *luminis*. It is the *dysopia* of Cullen; and the *amblyopia* of some writers is the amaurosis of Cullen. The remedy for this complaint is not easily assigned. The eyes of the myopes and presbytæ are said to be defective in their form, either too convex or too flat; so that the pencil of rays terminates before or beyond the retina, and distinct vision is of course impossible. The latter is more generally true than the former; for it must be obvious, that a deeper orbit, and consequently a more distant retina, or a stronger refracting power of the lens, may equally produce short-sightedness. In either case, there is no remedy but using glasses, about one number less than that which renders the vision perfectly distinct, or using the eyes to examine distant objects. Age however alone brings relief, and this at no long period before blindness ensues; yet it is more common for short-sightedness to continue to extreme old age, than for the short-sighted to be blind.

The presbytæ can scarcely, in any instance, procure strong or perfect sight. The weakness of vision may be relieved by cold bathing; cold applications to the eye; frequent ablutions with water, to which about 1-4th or 1-6th of good brandy has been added, by drawing sparks, or by Galvanism. The *amblyopia tenebrarum* arises from imperfect perception, and may be relieved, if relieved, by the same means. The opposite complaint, on the contrary, the seeing *only* by night, arises from too great sensibility, which renders common light excessive in its powers; and the disease is truly "*tenebræ per tantum lumen obortæ*." Age may lessen it, but medicines will have little effect. See Wallis's Sauvages' Nosology of the Eyes, p. 151, &c.

AMBLYO'PIA, HYDROPHTHA'LICA, i. e. CALIGO HUMORUM. See CALIGO. It sometimes means also AMAUROSIS.

A'MBON, (from ἀνίσταμαι, to ascend). The edge of the sockets in which the heads of the large bones are lodged.

A'MBRA. See SUCBINUM.

A'MBRA ARA'BIBUS. } From cineraceus, the colour  
A'MBRA CINERA'CEA. } of ashes.

A'MBRA GRI'SEA, (from gris, grey). Also named *succinum-griseum*, *succinum-cinereum*, *ambarum*, *ambra arabibus*, and in English AMBERGRISE.

Much of it is met with in the Indian Ocean, and on the African coast; pieces of a considerable weight have been found in the northern seas. Sometimes it is seen floating on the surface of the sea, at others adhering to rocks; not unfrequently discovered in the stomachs of fish, or thrown on the shore; but it is found most plentifully about the island of Madagascar and the Molucca Islands: yet that brought to England comes from the Bahama Islands, and from Providence, where it is found on the coast. According to an account in the Philosophical Transactions, No. 385, and 387, this drug is only the produce of the male spermaceti whale: it is there said to consist of balls, from three to twelve inches diameter, lying loose in a large oval bag three or four feet deep or wide, nearly in the form of an ox's bladder, with a pipe running into and through the penis, four or five feet below the navel, and three or four feet above the anus. This bag is almost full of a deep orange-coloured liquor, not quite so thick as oil, of the same scent as the *ambergrise* which swims in it. These balls of *ambergrise* seem to be in laminæ, like onions; and, in the fluid, pieces of the laminæ are found. There are two, three, or four balls in a bag. Where one whale hath these balls, three or four have only the liquor in the bag. Whether these bags are peculiar to the male, or the aged fish, has not been determined. But the whole account is probably hypothetical. Accurate observers have constantly told us that the *ambergrise* is mixed with bones of cuttle-fish and other animal debris. It cannot then have been formed in a bag, from whence there is no very ample excretory duct, since the masses found are of a large size; nor can it have been produced in a bag to which the food has not access, since *ambergrise* is mixed with bones and other remains of the aliment. In fact, the accounts above referred to are collected from the observations of whalers, who seem to have mistaken either the urinary concretions for *ambergrise*, or some secretory follicle, containing a substance similar to musk or castor. It is certain that the nature of the concrete was mistaken, since *ambergrise* very seldom appears to be composed of concentric coats. Neumann, Geoffroy, Cartheuser, and Macquer, think it a bitumen; but a paper was some years since presented to the Royal Society, by Dr. Swediaur, which asserts it to be an animal production, and the indurated fæces of the spermaceti whale. Messue calls it the spawn of the whale-fish. This opinion also is not very probable. It is not a fæculent substance, for it neither contains ammonia nor an ammoniacal salt; and we are informed by Geoffroy, that it is sometimes mixed with the beaks of birds, with honey-combs, even with their cells filled with honey: nor is it a natural production of the fish, since the whales in which it is found are poor and sickly, and do not evacuate their fæces when hooked. It

is still probable, therefore, that it is not an animal production. We know that animals of very different kinds are extremely fond of it; and not only the cetaceous tribe, but fish, crabs, birds, and quadrupeds, seek it with avidity. It is not however digestible, though it apparently contains some nutritious particles, and is voided with little change. The excrements of some birds are collected with peculiar care on account of their fragrance, owing to their having eaten *ambergrise*. If however it was a fossil, we should probably have found it in its fossil state: a single instance of this occurs in the volumes of the Academy of Sciences, among the memoirs of foreign philosophers, but it has been contradicted; nor is the opinion of Buffon, adopted by Sonnini, that it consists of animal substances, agglutinated at the bottom of the sea by a liquid bitumen, more probable. Dioscorides, and some other ancient naturalists, thought it a vegetable substance, and Aublet considers it as the same with the resin de coumieri; and the younger Linnaeus as the production of the *amyris ambrosiaca* Lin. Pl. Supplem. 216. Sp. Pl. ed. Wildenow, 335. vol. ii. If it must be an animal substance, it is probably derived from the food of the whale. Many of the molluscæ and cuttle-fish, on which whales feed, have the smell of *ambergrise*, particularly the *sepa tuberculata* of Montfort, and the *s. rugosa* of Bosc. The human excrementitious fluids often smell of *ambergrise*. The human excrement, in some of Homberg's experiments, was made to exhale this odour; and a towel employed to wash the hands, if shut up closely, is not very distant from it in smell.

Pure *ambergrise*, in its tenacity, softness, and easily yielding, resembles wax: it swims in rectified spirit of wine; grows soft in a very gentle heat; is opaque, rugged, of a greyish ash colour, mingled with yellow and white or greenish spots; it hath no particular taste, though softish, oily, and somewhat aromatic; it adheres to the teeth; when bitten affords but little smell, except it is heated, and then it is very fragrant; set on fire, its odour is like that of burning amber; with a small degree of heat it melts into an oil, without froth, and in a great heat it is volatile. It may be broken into scaly fragments, but cannot easily be powdered.

The genuine is speckled with green or black spots: the less it is variegated, the worse: the worst sorts approach to a deep black. Its purity is ascertained by penetrating it with a hot needle, when its peculiar odour will be exhaled.

It is soluble in boiling spirit of wine: from which, if the saturated solution be set in a very cold place, a part of the *ambergrise* concretes into a whitish unctuous substance. Distilled, it yields an aqueous phlegm, a brown acidulous spirit, a deep-coloured oil, a thicker balsam, and sometimes a little concrete salt. The spirit, oil, balsam, and salt, are similar to those obtained from amber, except that the oil is more agreeable to the smell.

Rectified spirit of wine takes up near 1-12th of its weight of *ambergrise*. According to Neumann, if the spirit is impregnated with a little essential oil, the *ambergrise* will dissolve more readily in it. A deeper coloured, but not stronger, tincture is made with alcohol. Dulcified acids and alkaline spirits have no effect upon it; water and expressed oils have as little.

It is one of the most agreeable perfumes: it height-

ens the natural odour of other bodies; but the great secret to this end is, to add it so sparingly, that while it improves the smell of that to which it is added its own may not be discovered. It has been given as a cordial, aphrodisiac and antispasmodic, but is neglected by modern practice. The preparations belong to the trade of the perfumer. The usual dose was from twelve grains to a scruple. Hoffman informs us, that a highly rectified spirit of roses, drawn off repeatedly from a fixed alkali, is its best menstruum.

A counterfeit as well as adulterated sort is too often to be met with; the first generally consists of musk, civet, storax, labdanum, and aloes wood, mixed together; the latter of a large quantity of bullock's blood, duly flavoured with musk and civet. See Neumann's Chem. Works, and Lewis's Mat. Medica.

A'MBRAM. See SUCCINUM.

AMBRE'TTE. The French name of ABELMOSCHUS, which see.

AMBROSIA, (from  $\alpha$ , *priv.* and  $\beta\rho\alpha\mu\alpha$ , *food*; superior to mortal aliment). The name of a sweet shrub, anciently used for making garlands. *Ambrosia maritima* Lin. Sp. Pl. 1401.

The modern ambrosia is the *botrys*, q. v. The ancients seem to have given this name to various plants, as the lily, the greater house-leek, &c. Gerrard. In chemistry, it implies a highly rectified tincture; and it is applied as a title of peculiar reverence to some ancient antidotes.

AMBULA'TIO, (from *ambulo*, to walk,) WALKING. See ÆORA.

AMBULA'TIVA, (from the same). See HERPES.

A'MBULO, (from  $\alpha\mu\beta\alpha\lambda\lambda\omega$ , to cast forth). The name of a disease called also *furiosus*, *flatulentus*, *flatus furiosus*. It is a distention or inflammation attended with pain, and variously periodical. See D. D. Joh. Michael. Prax. Clin. Special. Cas. 19.

AMBU'STA, (from *amburo*, to burn). BURNS, or SCALDS; called also *causis*, *ambustio*, *ambustura*. Dr. Cullen places this case as a variety of the phlogosis erythema.

A *burn* is from solid substances; a *scald* from any hot fluid, or solid when in a fluid state. Their danger is according to the degree, the part injured, the peculiarity of the constitution, and consequent symptoms. Wounds from burns are more liable to form a cicatrix than from other causes.

*Burns* differ in degree only. The slighter kinds resemble inflammation; those where much substance is destroyed, mortification.

In the slighter kinds, medicines that neither heat nor cool in a great degree are to be preferred. Cold water may be used, by means of linen rags dipped into it, and the application repeated as often as they become either dry or warm. In the same manner brandy and rectified spirit of wine may be applied, repeating the dressings until the pain abates, and then the camphorated spirit of wine is to be preferred.

Vinous and volatile spirits, if applied before the blisters rise, generally prevent them, and always moderate the inflammation; but if the injury is on a membranous or tendinous part, it is best to mix oil with the spirit, otherwise it will too much contract it.

To the same purpose as the above, and in want of

them, any of the following may be used:—The white of eggs beat thin; vinegar, in a quart of which one handful of common salt is dissolved; the pickle from olives; the brine from cabbage; oil of turpentine; any cooling oil or liniment; vinegar; lintseed or olive oil; apples or potatoes scraped, and applied as a cataplasm. If the blisters are considerable they may be punctured and dressed with any cooling ointment; and if digestion is necessary, a proportion of ung. resinæ flavæ be added. Should fever follow, the appropriate remedies must be employed.

In the severer kinds, if a crust is formed, the cure is effected by emollients and suppurants, as in the case of gun-shot wounds. See SCLOPETOPLAGA.

If the accident hath happened in the face, or, in females, in the neck, whatever can tend to increase the cicatrix must be avoided: emollients folded in linen cloths are the best applications; an emollient fomentation, with about two ounces of the camphorated spirit to a pint, may be used at the renewal of the other dressings, during the first three or four days, or until the crust is separated; after which the procedure will be as in any common wound.

If the crust remain firm above three days, make incisions through it, to discharge the matter underneath. To prevent a cicatrix, as the skin forms, let it be often exposed to the stream of hot water, and apply a cerate of wax and the oil of eggs.

Where all is destroyed even to the bone, Heister says, that the only method is amputation; but the methods here recommended will often succeed, and save the limb.

A violent head-ach in one, and pain in the limbs of another person, were removed by the parts affected being accidentally burnt, and that only slightly. Homberg thinks that burning with moxa, and with cauteries, cure by quickening the motion of the humours, by thinning them, and by destroying the ends of the vessels, by which the fluids flow less that way. On the whole burns can only be judiciously treated by considering them as high inflammations, of the erythematous kind, and the treatment must accord, by evacuates if necessary, and by bark; attending in each to the material benefit arising from removing pain by proper opiates, without which but little advantage will be gained, whatever other means are used. For BURNS, or SCALDS, the following preparations are esteemed as highly useful.

LINIMENTUM OLEOSUM—*oily liniment*. R. Olei olivarum  $\mathfrak{z}$  i. ss. aquæ calcis  $\mathfrak{z}$  iij. This is more particularly adapted to burns, especially where the skin is scorched, or destroyed, from its softening qualities: repeated affusion of, or continual immersion in, cold water, more conveniently relieves scalds.

CREMOR LITHARGYRI ACETATI. See PLUMBUM.

LOTIO LITHARGYRI ACETATI CAMPHORATI—*camphorated lotion of acetated litharge*. R. Sp. camphorati  $\mathfrak{z}$  ij. aq. lithargyri. acetati  $\mathfrak{z}$  i. gradatim commisceantur et paulatim adde aq. distillatæ  $\mathfrak{f}$  i. In topical inflammations, having a tendency to become erysipelatous, this possesses much efficacy.

LOTIO SPIRITUOSA—*spirituous lotion*. R. Spt. vini rectificat.  $\mathfrak{z}$  iv. aq. calcis  $\mathfrak{f}$  ss. This acts as a sedative, and alleviates the pain of the parts inflamed.

Mr. Cockburn recommends a plan, which we have found very successful. The part burnt is to be bathed with vinegar, till the pain is no longer felt; and this application is not contraindicated by even a loss of substance. Afterwards, a common poultice, covered with finely powdered chalk, is to be applied, and repeated at first every four hours, and after a day or two every six or eight hours. In a few days the cure is completed. The effect of this plan is the coagulation of the fluid in the blisters, and their immediate healing.

Mr. Kentish, of Newcastle, recommends the use of the *aqua ammoniæ*, oil of turpentine, or alcohol, as the first applications; and afterwards a dressing of the unguentum resinæ flavæ, softened with oil of turpentine, with a cordial diet and the use of opiates, from which he has been very successful in his practice in some extremely desperate cases; and in cases of costiveness he has recourse to calomel to keep the body moderately open.

He has given to the public several cases, with the modes of treatment he made use of; and as they must vary according to particular circumstances occurring, and differences of the constitutions in individuals to whom such accidents have happened, we refer the reader to the perusal of his work, as the nature of our publication will not permit us to descend too minutely unto such particulars as may be necessary to be known by the practitioner.

Bell's Surgery, vol. v. 357. Pearson's Elements of Surgery, part i. 159. White's Surgery, 24. Kentish on Burns.

AMBU'STIO, AMBUSTION, (from *amburo*, burning, or scalding). See AMBUSTIO and CALCINATIO.

AMBU'TUA. (Indian). See PAREIRA BRAVA.

AME'A, a plant used on the coast of Africa in bleedings of the nose; its powder is used as snuff.

AMENDA'NUS. See ALNUS.

AME'LLI, a tree growing on the coast of Malabar, described by Reed too imperfectly to be classed in systems. A decoction of its leaves is useful in colics, and its roots infused in oil are said to be good resolvents.

AME'LPODI. See BELLUTTA TSJAMPACAM.

AME'NE. See GEMMÆ SAL.

AMENORRHŒ'A (from *a*, neg. *μην*, mens, and *ρεω*, fluo). A DEFECT OR WANT OF THE MENSES, OR MONTHLY FLUX. See MENSES DEFICIENTES.

AMENE'NOS, (from *a*, negative, and *μενος*, strength). WEAK, FEEBLE. In this sense Hippocrates often uses this word.

AME'NTIA, (from *a*, privat. and *mens*, the mind). MADNESS, IDIOTIC INSANITY; also *anoia*, *fatuitas*, *oblivio*; FOOLISHNESS, IDIOTISM, &c. Some use *amnesia* as a synonyme. Dr. Cullen defines it to be the weakness of the mind in judging, from either not perceiving or not remembering the relations of things. He ranks this genus of disease in the class neuroses, and the order vesaniæ. His species are, 1. *Amentia congenita*, NATURAL STUPIDITY, i. e. from the birth. 2. *Amentia senilis*, DOTAGE, OR CHILDISHNESS, from the infirmities of age. 3. *Amentia acquisita*, when from accidental injuries a person becomes stupid or foolish. In the last of these only can we afford any relief; and this species arises from the powers of the constitution being greatly debilitated by preceding complaints, where the nervous system has been long and severely affected, and the mind equally debilitated:

cheerful company, gentle exercise in a pure clear air, a generous mode of living, properly regulated, and cordial medicines, if necessary, bid the fairest for performing a cure. See MANIA, MOROSIS, and MELANCHOLIA.

AMENTUM, a LOOP OR BOND, (from *αμνα*, a thong). It is also a name for SCISSILE ALUM. See ALUMEN PLUMOSUM.

AME'RI. (Indian.) See INDICUM.

AMERICA'NUM, BALS. See PERUV. BALSAMUM.

AMERICA'NUM TUBERO'SUM. AMERICAN POTATO, having a tuberous root. See BATTATAS CANADENSIS.

AMETHY'STA PHA'RMACA, (from *a*, neg. and *μεθυ*, wine). Medicines which either prevent or remove the inebriating effects of wine.

AMIA'NTHUS, (from *a*, priv. and *μαίω*, to pollute), so called from its white or silvery gloss, which is not easily defiled. Also called *asbestos*, *asbestinum*, *cinum fossile*, *asbestinum vivum*, *Indicum*, *corphasium*, *caristum*, and *Cypricum*; *alumen officinarum*, *Sparta folia*, *salamandra*, EARTH FLAX and SALAMANDER'S WOOL.

It is a magnesian earth composed of small silvery filaments; met with in many of the islands of the Mediterranean Sea, and in Italy. It is worked either into linen or paper, both which resist the most violent flame, and are cleaned by calcining. It is dug up also in the island of Anglesey, and in Oxfordshire.

AMI'CULUM. A covering for the pubes. It is also used in the same sense as the word AMNIOS.

A'MIDUM. See AMYLUM.

AMINÆ'A. A gum so called from AMINÆA, a place where it is produced. See ANIME.

AMINÆ'UM VINUM. WINE of AMINÆA; called afterwards *Falerium*, in Italy. It is a strong kind of wine.

AMINÆ'UM ACETUM. Vinegar of Aminæan wine, or any very strong wine vinegar.

AMISA'DU. See AMMONIACUS SAL.

A'MMA, (from *αμω*, to bind). See BRACHERIUM.

AMMAN. CHAR. PLANT. The abbreviation of *Ammari*, *Characteres Plantarum*.

A'MMI, (from *αμμι*, an urinal; because it provokes urine. *Sison ammi* Lin. Sp. Pl. 363,) or A'MMI VERUM; called also AMMI CRETICUM, *ammi parvum foliis fœniculi*, *ammi semine tenuissimo et odoratissimo*, *cuminum Ethiopicum*, *fœniculum annuum origani odore*, ROYAL CUMMIN, and TRUE BISHOP'S WEED. AMMI veterum is the *lagœcia cuminoides* Lin. Sp. Pl. 294.

The seeds of these plants only are used in medicine. The common sort is a native in the southern parts of Europe; and the seeds of this species are larger, paler, and very different in flavour, as well as in medical power, from the true, which is a native of Egypt; and the seeds are of a reddish brown colour, small, and flat on one side, convex and furrowed on the other. We very rarely meet with them; the seeds of the amomum, and of parsley, being often sold for them.

The seeds of the true bishop weed are an agreeable carminative, of a moderately warm taste, resembling organum in their smell. By distillation with water, they yield much oil of a yellowish colour, and contain-

ing their whole flavour; spirit of wine also conveys their odour. These seeds have been recommended as emmenagogues and diuretics, but are only moderately warm stomachics.

A'MMION. See CINNABARIS.

AMMOCHO'SIA, (from *αμμος*, sand, and *χρῶ*, to pour). A remedy for drying the body, by covering it with hot sand, or salt, which is preferable.

AMMONIA MURIA'TA. See AMMONI'ACUS SAL.

AMMONIA PREPARA'TA, *olim* SAL VOLA'TILIS SALIS AMMONIA'CI.

AMMONIA AQUA, *olim* SPS. SALIS AMMONIACI.

AMMONIA AQUA PUR'E, *olim* SPS. VOLA'TILIS CAU'STICUS. See A'LCALI VOLATILE. There are several preparations wherein ammonia is considered the principal ingredient, and upon which, in many cases, practitioners fix their chief dependence.

LINIME'NTUM AMMO'NIÆ; *volatile liniment*.—R. Olei olivar.  $\frac{3}{4}$  i. ss. aq. ammon.  $\frac{3}{4}$  ss. m.—if required stronger, 1 oz. of ammonia is added to 2 oz. of the oil. This is an excellent, though not very powerful, application in rheumatic affections and sore throats.

LINIME'NTUM AMMO'NIÆ OPIA'TUM; *opiated liniment of ammonia*. R. Aquæ ammon. puræ  $\frac{3}{4}$  ij. opii purificati,  $\frac{3}{4}$  i. ss. sp. vini tenuioris lb i. digerantur simul donec opium omnino solvatur.—In rigid and painful swellings of the joints, this is considered as possessed of much efficacy.

LINIME'NTUM PETRO'LEI BARBADA'NSIS AMMONI'ATUM, *ammoniated liniment of Barbadoes tar*. R. Petrolei Barbadosis  $\frac{3}{4}$  i. ss. aquæ ammoniæ puræ  $\frac{3}{4}$  ss. m. In diseases of the hip, and other joints, this remedy is strongly recommended by Dr. Kirkland.

LINIME'NTUM CAMPHORÆ AMMONI'ATUM, *ammoniated liniment of camphor*. R. Aq. ammon. puræ  $\frac{3}{4}$  ij. olei olivarum  $\frac{3}{4}$  i. camphoræ  $\frac{3}{4}$  ij. In oleo solvatur camphora, deinde adjiciatur gradatim aquæ ammoniæ pura. This is employed by some practitioners in deep seated inflammations, or to parts that suppurate imperfectly, in order to quicken their action.

LOTIO AMMO'NIÆ ACETA'TÆ, *lotion of acetated ammonia*. R. Aquæ ammoniæ acetatæ. spt. vini rectificati, aq. distillat. añ. p. æ. m. This is used in external inflammations, and applied in the same cases as the lotio ammoniæ muriatæ. See AMMONIACUS SAL.

AMMONI'ACI EMPLA'STRUM cum HYDRA'RGYRO, *olim Emplastrum*. Ex AMMONI'ACO cum MERCURIO. P. L. 1788. R. Ammoniaci colat. p. lb i. hydrargyri purificati p.  $\frac{3}{4}$  ij. olei sulphurati p.  $\frac{3}{4}$  i. vel quod satis fit. Rub the quicksilver with the sulphurated oil, until the globules disappear, then add gradually the ammoniacum in a liquid state, and mix. Five ounces of this plaster contain an ounce of quicksilver; and it is applied to indurated glandular tumours, in order to disperse or bring them to suppuration.

AMMONI'ACUM. GUM. Called also *armoniacum*, but improperly; *hammoniacy lachryma*, *assac*, *azac*: and in English, GUM AMMONIAC.

It is a concrete gummi-resinous juice, produced in the East Indies, and brought in masses from Ammonia, consisting of little lumps, which inwardly are very white, but outwardly yellowish or brownish; its whitest parts become yellow on being exposed to the air. From

what plant it is obtained we know not; but, according to Dioscorides, it is from a shrub called ARGASYLLIS. It has been supposed with great probability to be an exudation from a species of ferula; another species of which produces asafœtida. It hath a strong smell, somewhat like that of galbanum, but not so disagreeable; a nauseous sweetish taste mixed with a bitterness.

Such pieces as are white, clear, dry, and large, should be preferred for internal use.

Thrown on live coals, it burns away in flames; it is soluble both in water and vinegar into a kind of milk; but the resinous part, which is nearly one half of the whole, subsides on standing: spirit of wine dissolves near one half of it, taking up all its active parts.

Dr. Deducer says, that lb i. of this gum, afforded by distillation of phlegm  $\frac{3}{4}$  vi. volatile spirit  $\frac{3}{4}$  ij. a volatile fetid oil  $\frac{3}{4}$  vi. But other skilful chemists have failed to obtain any oil from it by this process. Water is very slightly impregnated with it by distillation.

This drug has been esteemed a deobstruent, and an useful medicine in hysteric complaints; but modern practice confines its internal use to its expectorant powers in asthma, and difficult breathing: it gently moves the belly, and externally applied with squills, it has been recommended for resolving indurated tumours. See AMMONIACI EMPLASTRUM cum HYDRARGYRO.

The dose may be from gr. x. to  $\frac{3}{4}$  ss. three times a day, dissolved in water, when it is called lac ammoniaci; or in pills, which is the most agreeable form.

It is adulterated with common resin, and the method of purifying it is, by softening it in a bladder, which is immersed in boiling water; and straining it while fluid: but for inward use, the best is the largest and most unadulterated pieces.

AMMONI'ACUS, SAL; AMMONIA MURIA'TA; called also *cyreniacus sal*, AMMONIAC SALT and ARMONIAC, but improperly; likewise *alemzadar*, *alemzadad*, *adarige*, *aguila*, *alfol*, *alacab*, *alazale*, *alcob*, *alfatide*, *aliocab*, *alisteles*, *almisadar*, *anotasier*, *hasacium*, *musadi*.

Many writers speak of the natural and artificial. The natural sort, spoken of by the ancients, according to Dioscorides, is only the sal gem, and is reckoned by them among the alimentary salts; but others say that it was made from the urine of camels, and was deposited in the sands near the temple of Jupiter Ammon. We have no evidence of native sal ammoniac of this sort being found. Tournefort observes, that out of the simple native salts other compounded salts are naturally produced, viz. the essential salts, which naturally are concreted from the juices of plants, among which are native ammoniacal salts.

The artificial is the only sort known and used in the shops. It is a neutral, composed of a volatile alkaline salt and the acid of sea-salt; hence the term ammonia muriata.

Sal ammoniac is brought to us generally in round cakes, convex on one side, and concave on the other, from the shape of the vessels into which they are sublimed. When these cakes are broken, the salt appears of a needled texture, or composed of stræ, running transversely and parallel to one another: the internal

part is generally pure, and of an almost transparent whiteness; the outside, for the most part, is foul, and of a yellowish green or black hue.

In England, this salt is obtained from burnt cows' dung; it is obtainable from every species of soot by sublimation or solution. At Newcastle, it is made from the bittern, which remains after making common salt, and old urine; from one hundred pound weight of the bitter cathartic salt, and three hogsheds of urine, fifty-six pounds of sal ammoniac are obtained. In Egypt it is made from the burnt dung of quadrupeds that feed exclusively on vegetables. This dung is collected only in the first four months in the year, when the cattle feed on spring grass, which is a sort of clover: at other seasons, and when the cattle eat other sort of food, it is unfit for this purpose. As to the camel, its excrements are not preferable to those of any other cattle which feed on grass, nor is their urine ever used. Mr. Hasselquist says, that the salt-workers in Egypt pretend, that the excrements from men, goats, and sheep, are preferable to all others; and he further tells us, that March and April are the only times in which they make this salt. See the account in his voyages.

<p>It may also be produced from</p> <p>A'CIDUM MURIA'TI- CUM TINCT. FERRI MU- RIA'TI</p>	<p>} with {</p>	<p>Sal. C. C. Ammónia. pp. Sal. fuliginis. Sp. Ammón. composi- tus. Sps. Ammóniæ comp. fêti- dus. Liquor C. C. Aq. Ammónia. Ammónia acetata.</p>
--	-----------------	--

Consequently the tinc. ferri muriati, and the hydrargyrus muriatus, will be decomposed by either of the preparations in the second column.

The ammoniac salt is soluble in water and in spirit of wine, and in the air alone. It renders water extremely cold during solution; and when dissolved and mixed with a vitriolic acid effervesces violently, producing a sense of cold. Its crystals resemble feathers, or long shining spicula.

Mixed with a fixed alkaline salt, and then sublimed, it affords a dry volatile salt; but mixed with quick-lime, its volatile parts are only to be obtained in a liquid form. When unmixed, it may be sublimed with a considerable degree of heat, without the least change in its nature or properties; but if the fire is hastily raised during its sublimation, it volatilises many kinds of bodies mixed with it.

On account of its sea-salt, it turns diluted nitrous acid into aqua regia, but does not curdle milk, nor alter the colour of an infusion of roses.

Rubbed with quick-lime, or with a fixed alkaline salt, it emits an urinous smell, though dry. If a little hydrarg. mur. be added to its solution in lime water, the mixture becomes of a yellow colour.

In soldering, tinning, and casting shot, the crude salt is much used. It becomes volatile in a heat somewhat greater than that of boiling water.

Boerhaave says, that it preserves all animal substances from putrefaction; that its brine penetrates deeply;

that it is one of the most efficacious, aperient, attenuant, and resolvent medicines, a good sternutatory, diaphoretic, sudorific, and diuretic.

When used externally as a discutient, or detersive, it is mixed with some proper fomentation, in the proportion of  $\frac{3}{4}$  vi. or  $\frac{3}{4}$  i. to  $\frac{1}{2}$  ij. of the liquid.

It is more pungent to the taste than common salt, but is less antiseptic; it is a more powerful sudorific, and a less active purgative. In large doses, as  $\frac{3}{4}$  ij. it opens the belly, and in yet larger it proves emetic; it is a good febrifuge, and peculiarly assistant to the bark. In many instances, where the bark and emetics failed in agues, the crude salt given to  $\frac{3}{4}$  i. every four hours, with an infusion of camomile flowers, for some days, then every six, and at least every eight hours, hath succeeded: it is used both as an antiseptic and a repellent in gargles; when the throat is inflamed, it powerfully dissolves viscid mucus in the mouth and fauces. In violent hypochondriac cases it hath been of singular efficacy, by a daily use of it in doses just within what are required to render the bowels lax, or perhaps in such as produce a slight looseness; after taking it six, eight, and twelve months, the cold bath hath completed the cure. From  $\frac{3}{4}$  i. to  $\frac{3}{4}$  ij. dissolved in  $\frac{3}{4}$  viij. of any simple water, is a good substitute for the common saline mixture, and may be given, as to quantity and time, in the same manner. Dr. Cullen, however, doubts of these powers. He does not admit of its attenuating or dissolving the fluids; but, like other saline matters, in passing by the excretories it may be suited to promote their discharge. With the Peruvian bark, it may be of some use as a diaphoretic; but he doubts that in obviating the consequences apprehended from the use of the bark it can be of any service: nor does he allow that, externally applied, it has the power of discussing tumours, otherwise than by giving a moderate stimulus to the vessels on the surface; not by entering the pores, and by that means attenuating the viscid fluids. *Materia Medica*, vol. ii.

Truth, as usual, perhaps lies between. Like other neutrals, it seems to assist the febrifuge power of the bark, and prevent the latter producing the stricture on the surface, which sometimes occasions great inconvenience. Yet we have not been aware that it is more useful than any other neutral. It does not act as a laxative, but in a dose that is not agreeable to the stomach, and that few will persist in. As a gargle and a discutient, however, it may act; we have found it highly useful. Mr. Jutamond strongly recommends the following in the cure of the milk abscess. R. Ammoniac muriatæ  $\frac{3}{4}$  i. sps. ro-  
ris marini  $\frac{1}{2}$  i. m. Linen rags should be dipped into this, and kept continually moist on the part affected. Am-  
moniac muriatæ  $\frac{3}{4}$  ss. aceti. sps. vinosi rectificati, aa  $\frac{1}{2}$  i. m. is also an useful application.

The impurities of this salt will not dissolve in common water; and the purification is consequently effected by the solution and filtration. The very last crystals seldom betray any mixture of any other salt.

Preparations of this drug are the ammonia prepared. FLOS SA'LIS AMMONI'ACI, which is only the salt sublimed; and hath been called *aquila alba philosophorum*, and *aquila Ganymedis*.

AMMONI'ACI VEGETABILIS, Sal. See SP. MINDERERI, under ALALI.

AMMO'NIÆ ACETA'TE LINIME'NTUM. See AMMONIA.

AMMONI'TRUM, (from *αμμος*, sand, and *νιτρον*, nitre). In our glass-houses called FRIT. See FRITTA.

AMMO'NI COLLYRIUM, (from *αμμος*, sand). A collyrium which removes sand or gravel from the eyes; called also *hygidion*. It is a mere farrago.

AMNE'SIA, or AMNE'STIA, *αμνηστια*, (from *α*, priv. and *μνησις*, memoria). FORGETFULNESS. See AMENTIA.

A'MNION, or A'MNIOS, (from *αμνος*, a lamb, or lamb's skin). Martinus thinks it hath its name in allusion to *αμνιον*, a vessel, used for the reception of blood in sacrifice. It is also called *armatura*, *agnina membrana*, and *pellicula*, *charta virginea*, *galea*, *indusium*, *amiculum*. THE INTERNAL MEMBRANE WHICH SURROUNDS THE FŒTUS. It is a fine, thin, transparent membrane, soft, but tough, smooth on its inside, but rough on the outer. Dr. Hunter says, that it runs over the internal surface of the placenta, and that this membrane, which seems not vascular in the human subject, makes the external covering of the navel string, to which it is most firmly united; and that viewed in a microscope, it appears to have blood vessels, but they are lymphatics. It is found in all animals, both viviparous and oviparous. The fluid contained in the amnios is of a dilute white colour, transparent by filtration, with a faint smell: it contains an albumen similar to that of the blood, muriated soda, and an uncombined alkali, with a small proportion of animal matter. In the liquor amnii of the cow there seems to be a peculiar acid, styled the amniotic acid. *Annales de Chimie*, xxiii. 269.

AMOGA'BRIEL. See CINNABARIS.

AMO'MI. See PIPER JAMASCENSE.

AMO'MUM, (from HUMAN, Arabic, a pigeon,) whose foot it was thought to resemble. STONE PARSLEY.

Botanists enumerate three species, viz. the true, the bastard, and as a third sort, the tree nightshade is included.

The *amomum verum* is also called *amomum racemosum*, *carofi*, *elettari primum*, Hort. Malab. TRUE AMOMUM, or TRUE STONE PARSLEY.

The seed is the only part that is considered as medicinal, but it is not known whether the true *amomum* of the ancients exists or not; the most probable account is that of P. G. Gamelli, in the *Philos. Trans.* which is, that the *tugus*, called by some *birao*, and by others *carofi*, is the genuine *amomum* of Dioscorides. See Dr. James's Dict. article AMOMUM.

Many confound the *amomum* with great cardamom.—It is a native of China. The college of Edinburgh supply the place of the *amomum verum* with the *caryophylli aromatici*. The college of London have rejected it.

The *amomum vulgare* is the *sison amomum* Lin. Sp. Pl. 362, also called *sinon*, *amomum Germanicum*, *sisum aromaticum*, BASTARD STONE PARSLEY.

Its seeds, the only part used in medicine, are ripe in August; have a light agreeable smell, a warm, bitterish, aromatic taste; and are esteemed as carminative and diuretic. They are not so hot and pungent as, by the best accounts, the true *amomum* seeds are, nor is their flavour of the same kind.

All their virtue rises with water in distillation; but

by boiling in an open vessel, it is soon lost in the air, they yield their virtue also to spirit of wine.

The third sort resembles the common nightshade.

See Dale and Miller. It is also a name of the *cassia caryophyllata*, and *figier Jamaicensis*.

AMO'MUM CARDAMOMUM. See CARDAMOMUM.

AMO'MUM SCAPO NUDO. See ZEDOARIA.

AMO'MUM GRANUM PARADISI. See CARDAMOMUM MAJUS.

AMONGA'BRIEL, or AMOGA'BRIEL. See CINNABARIS.

A'MOR, LOVE, (from HANAN, Hebrew, to burn; or AM, a mother; because love is the natural passion of mothers to their children). Though not itself a disease, it produces diseases.

The symptoms produced by love are as follow: the eye-lids often twinkle, the eyes are hollow, and yet appear as if full with pleasure; the pulse is not peculiar to the passion, but the same with that which attends solicitude and care; when the object of this affection is thought of, particularly if the idea is sudden, the spirits are confused, the pulse changes, and its force and celerity are very variable: in some instances the person is sad and watchful; in others, not conscious of his state, he pines away, is slothful, and regardless of food; though the wiser, when they find themselves in love, seek pleasant company and active entertainments.

As the force of love prevails, sighs grow deeper, a tremor affects the heart and pulse, the countenance is alternately pale and red, the voice is suppressed in the fauces, the eyes grow dim, cold sweats break out, sleep absents itself, at least until the morning, the secretions become disturbed, and a loss of appetite, a hectic fever, melancholy, or perhaps madness, if not death, constitute the sad catastrophe.

Æginet. lib. iii. cap. 17. Oribas. Synop. lib. vii. cap. 9. or a treatise professedly written on love, as it is a distemper, by James Ferrard, Oxford, printed 1640.

AMO'RIS PO'MA; also called *lycopersicon*, *solanum pomiferum*, *mala aurea*; LOVE APPLE. *Solanum lycopersicum*, Lin. Sp. Pl. 265. It is a species of *solanum* about the size of a cherry, green at the first, and of a yellowish red colour; the flowers resemble those of nightshade; the fruit is fleshy and soft; it contains many flat whitish seeds in a juicy pulp. The plant flowers in July, and the fruit ripens in September.

Their quality is cooling. In Italy they are eaten with oil and vinegar.

See Miller Bot. Off.

AMORGE, (from *αμεργω*, to press out). See AMURCA.

AMO'STEUS. See OSTEOCOLLA.

AMO'TES. See BATTATAΣ HISPANICA.

AMPE'LION, (from *αμπελος*, a vine). VINE LEAVES, or THE TENDRILS OF VINES. Hippocrates commends them for making pessaries to promote the menses.

AMPELI'TIS, (from the same). CANNEL COAL. Named also *terra* or *lapis ampelites*, *pharmacitis*, *obsidianus lapidis*, *carbos*.

This species of coal is a bituminous earth, black as jet, and so hard that it takes a good polish, and is made into boxes, basins, and various other utensils. It contains much sulphur and salt, is divided into scales and

easily powdered; when old, that is, when long kept after taking it out of the mines, it falls into powder, and then yields a quantity of saltpetre.

It burns more bright than any other kind of coal: powdered and strewed upon vine trees it destroys the worms that injure them, hence its name: it is rarely used in medicine, but is commended as being more drying than terra Samia, or than many of the earths that have been employed with credit in medicine.

AMPELOCA'RPUS, (from *αμπελος*, a vine, and *καρπος*, fruit,) so called, because its seeds resemble the young fruit of the vine. See APARINE.

A'MPELOS. See BRYONIA.

AMPHARI'STEROS, (from *αμφω*, both, and *αριστερος*, the left hand). It is the reverse of ambidexter, that is, not having a proper use of either hand. Figuratively it signifies unlucky or unfortunate.

AMPHEMERI'NOS, AMPHEMERINA. It is the continued fever of Linnæus and Vogel, (from *αμφι*, a Greek preposition, signifying a revolution, and *ημερα*, a day,) a quotidian intermittent. See QUOTIDIANA FEBRIS.

It is by some considered a remittent fever, in contradistinction to the febris quotidiana, which is an intermittent, and is defined a kind of remittent fever, whose paroxysms return every day of a similar nature, though it is rarely observed to be regular. Sauvages enumerates no less than twenty-four species.—See Sauvages, vol. ii. p. 322.

AMPHIARTHO'SIS, (from *αμφω*, both, and *αρθρωσις*, an articulation). A mixed sort of articulation, partaking of the diarthrosis and the synarthrosis; it resembles the first in being movable, and the latter in its connection. The species which compose it have not a particular cartilage belonging to each of them, as in the diarthrosis, but they are both united to a common cartilage, which, being more or less pliable, allows them certain degrees of flexibility, though they cannot slide upon each other; such is the connection of the first rib with the sternum, and of the bodies of the vertebræ with each other. See ARTICULATIO.

AMPHIBI'BIUS, AMPHIBIOUS, (from *αμφω*, and *βιος*, life). Animals are thus called that are capable of living as well by land, or in the air, as by water.

Though it is not our design to treat of subjects which belong to natural history, yet, respecting this class, there are various facts applicable to the human body in a sound or a diseased state. The term is confined to animals with a single heart, whose respiration is in a great degree voluntary. There is probably no amphibious animal, in the strictest sense of the word; for no animal has, at the same time, lungs and gills. The siren, which induced Linnæus to form a new order from this circumstance, is probably an imperfect animal in its progressive state. That lately described by Schreber, in the Philosophical Transactions, seems, from the arguments adduced in the Critical Review, to be equally so. Frogs, which in their early state breathe by gills, lose them when more perfect; and, if carefully watched, they may be found, at some period, in possession of both organs. The molluscæ, and shell fish, breathe by gills; but it is pretended that some species can breathe air as well as water by those organs. If so,

these are truly amphibious. The crustaceous animals, particularly the crab, can apparently breathe both air and water; but this power is limited in its duration. In short, animals are destined to live wholly on land or wholly in water. The real amphibia are very few, and among those whose habits are little known. Other animals differ in the duration of the period when they can leave the element most congenial to them, but in either it is short.

The lungs of the amphibia differ in their structure from those of more perfect animals; but we have yet to learn how they are better adapted to a longer residence in water than those of the mammalia and aves. The heart, we have said, is single: it is certainly so in every physiological view, and the blood is not necessarily conveyed through the lungs, as in the other classes. It either attracts oxygen more rapidly, while it is exposed to air, or combines more difficultly with carbone. As the cartilaginous fish are now removed to the pisces, we find only two orders of amphibia—those with feet, and those without; the reptiles and the serpents.

The bones of the amphibia are less firm than those of other animals, and they approach, in their mode of reproducing lost parts, the vegetable kingdom. The principle of life is not confined to one organ, but exists in a less degree in different parts, as in the buds of vegetables. Thus they are more tenacious of life, and can endure longer abstinence than other animals. As their eggs are not so much exposed to shocks or the action of hard bodies, they have not, in general, such solid coverings as the eggs of the aves. All the amphibia are perhaps oviparous: those which appear viviparous, are apparently hatched within the body, and excluded from the egg and the mother about the same time.

Dr. Parsons divides the amphibia into such as chiefly live on land, and dive only occasionally, or those who rise to the air only at times to breathe. The former have, in many instances, the foramen ovale closed. It is so in the otter. Men used from the earliest period to diving, can exist a long time under water, and it has been supposed that the foramen ovale is open. It has, however, never been found so; and of those where the blood does not pass through the lungs, the complexion is of a blue colour. The stories of the Calabrian, and the young Sicilian named *fish Colas*, have been apparently much exaggerated.

AMPHIBLESTROI'DES, (from *αμφιβληστρον*, a net, and *ειδος*, forma). The RETINA, or NET-LIKE COAT OF THE EYE; also the same as RETIFORMIS, which see; and VERRICULARIS TUNICA.

AMPHIBRA'NCHIA, (from *αμφι*, about, and *βραγχια*, the fauces). The fauces or parts about the tonsils.

AMPHICAU'STIS, (from *αμφι*, about, and *κυστρα*, a ditch). A sort of wild barley; so called because it grows about ditches. See also PUDENDUM MULIEBRE.

AMPHI'DEON, or AMPHIDÆ'UM, (from *αμφι*, on both sides, and *διαιω*, to divide). The mouth of the womb, which opens both ways. See OS INTERNUM.

AMPHIDE'XIOS. See AMBIDEXTER.

AMPHIDIARTHO'SIS, (from *αμφω*, both, and *διαρθρωσις*, articulated). So Winslow calls the articulation of the lower jaw, which is partly by a ginglymus, and partly by an arthrodia.

AMPHIMERI'NA HUNGARICA, (from *αμφι*, about, and *μερα*, a day,) called also *morbus Hungaricus*; *cephalynosa*; *febris Hungarica*, *castrensis*, and *carceris*; *languor panonicus*: is said to be a kind of tertian remittent fever. Sauvages calls it *asthenia panonica*, and doubts whether or no it differs from *typhus*. It affects chiefly soldiers in camp; and is sometimes epidemic, gradually destroying the functions of the machine, and in the end proving fatal.

AMPHIMERI'NA CATARRHA'LIS. See CATARRHA'LIS FEBRIS AMPHEMERI'NA.

AMPHIMERI'NA TUSSICULO'SA. See CATARRHUS.

AMPHIMERI'NA ANGINO'SA. See SCARLATI'NA ANGINO'SA.

AMPHIME'TRION, (from *αμφι*, about, and *μετρα*, the *umbil*). The parts about the womb.

A'MPHIPLEX, (from *αμφι*, about, and *πλεξω*, to connect). According to Rufus Ephesius it is the part situated betwixt the scrotum, anus, and internal part of the thighs.

AMPHIPNEU'MA, (from *αμφι*, about, or around, and *πνευμα*, breath). See DYSPNEA.

AMPHISBÆ'NA, (from *αμφι*, either way, and *βαινω*, to go). Galen says, it is an animal with two heads. Aetius describes it as a venomous serpent, which moves with either end forward, from which circumstance it hath its name; and says, the bite is like the sting of a bee, as to its effects, though somewhat more violent, but it is cured in the same manner. The serpent which bears this name in modern systems, has no resemblance to that described by the ancients, and is not venomous.

AMPHISMI'LA, (from *αμφι*, on each side, and *σμιλη*, an incision knife). A dissecting knife with an edge on each side.

AMPHI'TANE, (from *αμφι*, and *ταναος*, extended). See TINCAL.

AMPHODO'NTA, (from *αμφι*, on both sides, and *οδης*, a tooth). By this word, Hippocrates expresses animals that have teeth in both jaws.

A'MPHORA. A Roman measure for liquids, (from *αμφιορεω*, by a syncope *αμφορεω*; it is called so from the two handles for carriage; *αμφι*, on both sides, and *οερω* to bear). Its contents are seven gallons and one pint English.

AMPO'TIS, (from *αναπινω*, to regurgitate). The RECESS OF EBB OF THE TIDE. Hippocrates used this word to express the recess of the humours from the circumference to the centre of the body.

AMPU'LLA, (from *αναελλα*, to swell out). In chemistry all bellied vessels are called *ampullæ*, as BOLF-HEADS, *excisiula*, or RECEIVERS, CUCURBITS.

AMPULLA'SCENS, (from *ampulla*). The alvus *ampullascens* is the most tumid parts of Pecquet's duct: in modern language, the receptaculum chyli.

AMPUTA'TIO, AMPUTATION, (from *amputo*, to cut off). It is the cutting off a limb. *Ectome*, *excisio*, and *extirpatio*, are used in the same sense. *Excisio* may indeed be applied to the operation where one part is cut out of another, as some encysted tumours.

Hippocrates says, when speaking of a mortification, that what is putrified must be cut off, but does not mention the taking off limbs. Celsus is the first who describes this operation. Till the sixteenth century, we have no account of any method to prevent the hæmorrhage which happens in this sort of operation, except

Celsus's, of making a ligature about the vessels. Pare tells us, that, previous to making this incision, a ligature, with a thin fillet, must be made above where the amputation is to be performed, which, he says, first, keeps up the skin and muscles in a raised posture; secondly, prevents an hæmorrhage; and, thirdly, lessens the sense of feeling. He is the first who clearly speaks of preventing the hæmorrhage, when these operations are performed. In 1674, Mr. Morel, a French surgeon, introduced the tourniquet, as it is now used: but the first mention of this instrument is in the *Currus Triumphalis à Terebintho*, published in London by an English surgeon in 1679. About the end of the seventeenth century, Messrs. Verduin and Sabourin, one a Dutchman, the other of Geneva, left a label of the flesh and skin to wrap over the stump, and called it 'l'opération de l'amputation à lambeau;' but they probably learnt it from an Englishman, who published this practice in 1679; see *CURRUS TRIUMPHALIS E TEREBINTHO*. Paulus Ægineta used the actual cautery; but Ambrose Paré secured the vessels by drawing them a little out with the forceps, then making a ligature round them, as is often mentioned by Celsus, though neglected by so many of his successors. In the present (eighteenth) century, improvements are both many and important in this branch of surgery; the crooked needle, and most other parts of the apparatus, being now introduced or improved.

#### CASES REQUIRING THE LIMB TO BE TAKEN OFF.

Mr. Bilguer, an eminent practitioner in the armies of the king of Prussia, during his late wars, reduces them to six, as follow:

1. A mortification, which spreads until it reaches the bone.
2. A limb so hurt, that a mortification is highly probable.
3. A violent contusion of the flesh, which at the same time hath shattered the bones.
4. Wounds of the larger blood vessels of the limb, when recourse is had to amputation, as the only method of stopping the hæmorrhage; or through an apprehension that the limbs should perish for want of nourishment.
5. An incurable caries of the bones.
6. A cancer or humour in danger of becoming such.

Perhaps Mr. Bilguer may have restrained this operation rather too much; but his ingenuity renders his instructions deserving of attention.

In cases from mortification, Mr. Sharpe hath well established the propriety of waiting until it ceases, and granulations of new flesh show a better state of the constitution. He observes that gun-shot wounds are best, if the necessary amputation is immediately performed; and that the disorders of the joints, ulcers of long standing, and all scrofulous tumours, generally return on other parts after amputation.

Mr. Pott observes, that in the instances generally demanding amputation, if the rule is adhered to, a limb will now and then be taken off that possibly might have been restored; but the number is so small, in proportion to those who, under the same apparent circumstances, would end fatally, that it can make no

difference in the general treatment. Selection of one case from another is what constitutes judgment in surgery; and happy is the man who, amidst the following demands for amputation, singles out the circumstances in which he will succeed, and save the threatened part. In general, then, amputation is necessary—

1. In some compound fractures. See *FRACTURA*.

2. A wound in the principal artery of a limb; in some aneurisms; a large wound with loss of substance, from arteries not contained within the cavity of the body, as those of the thigh, leg, or arm. It is true, every instance of a wounded humeral or crural artery does not demand this operation; but if the wound is such, that the collateral branches in their neighbourhood are prevented from carrying on the circulation, a speedy amputation will be necessary. See *ARTERIA; FEMORALIS ARTERIA; POPLITEA ARTERIA; TIBIALIS ARTERIA; HUMERALIS ARTERIA, &c.*

3. When joints are wounded, violently injured, or otherwise diseased. When the heads of bones are diseased, or their ligaments lacerated, in most instances amputation is necessary. See *VULNUS, SCLOPETOPLAGA, SPINA VENTOSA, &c.*

4. A caries of the whole substance of a bone, or of the bones which compose a limb. See *CARIES*.

5. Some mortifications. See *MORTIFICATIO*.

6. Many instances of gun-shot wounds. See *SCLOPETOPLAGA*.

7. Cancers. See *CANCER*. Extensive foul ulcers, and some deep-seated encysted tumours.

8. Swellings of the bones or deformed limbs.

9. A disease resembling the œdema described by Richter.

Large bones should not be amputated in the joint, on account of the extreme thinness of the flesh in those parts, which cannot easily be brought to cover the bone, whence many inconveniences may arise; but if there is a probability of succeeding in this respect, the objection vanishes.

If amputation is determined on, the following should be in readiness:

1. A tourniquet.

2. A smooth fillet, an inch broad, and half an ell long.

3. The amputating knife.

4. A catlin.

5. Saws of different sizes, particularly a small one made of a watch spring for splinters.

6. A forceps—a small pair of scissors with long handles.

7. Crooked needles, armed with wax thread.

8. Lint and tow, made into compresses ready for use; tapes and adhesive plaster in slips.

Calomel mixed with starch, and strewed on a pledget of lint, is perhaps the best application to the stump of an amputated limb.

9. A retractor.

10. A roller of five ells in length; the many-tailed bandage, or a woollen cap.

11. Pledgets of sponge.

12. Cordials to raise the patient's spirits, and proper attendants.

Previous to amputation, a large dose of the tincture of opium is sometimes given to lessen pain; and we have sometimes ordered, with advantage, the tourniquet

to be placed and screwed moderately tight for an hour previous to the operation.

#### AMPUTATION of the ARM.

In most amputations, the operation should be a finger's breadth, or more, above the sphacelated, or otherwise injured part.

Apply the tourniquet so, as that it may press upon the chief artery of the limb to be taken off. When the arm is the part to be amputated, some recommend a pressure on the artery as it passes over the first rib.

Then let an assistant draw the skin back, while the operator binds the fillet round where the incision is to be made. This fillet both guides the knife, and keeps the flesh tight, so that it more easily yields to the knife; or more exactly to make the circular incision, a slip or two of plaster may be preferred to the fillet for directing the knife; two slips may be laid, the one upon the other; and if another slip is placed about three-fourths of an inch higher, its effect will greatly assist those of the lower.—On the exact cutting the skin, muscles, &c. the speedy cure of the stump very much depends.

Having proceeded thus far, give the patient a cordial, and cheer him.

Two assistants holding the limb in a straight line, an incision must be made quite round through the skin and fat to the flesh; then take away the fillet or slips of plaster; and the assistant, who holds the upper part of the limb, must draw the skin as far back as he can; after which, as near the edge of the retracted skin as possible the flesh must be divided, at twice, to the bone; and if there are two bones, divide the flesh between them with the point of the same knife. That the bone may be sawed off as near to the edge as possible, it is necessary to cut the skin, &c. to the muscles first, that you may draw it back, and cut the flesh as far under the skin as possible, in order to having the skin to reach over the flesh and the bone of the stump as soon as it is dressed. To assist this intention of bringing the skin over the end of the stump, the retractor is contrived, which must be put on after the incision is made through the muscles, to draw them up, as forcibly as the patient can easily bear: thus the bone can be sawed off more closely to the edge of the flesh, and with less danger of tearing it with the teeth of the saw. When there are two bones, as in the fore-arm, after having cut through the muscles, and divided the interosseous ligament, some recommend, instead of the retractor, to pass a compress between the bones, and therewith to draw back the divided parts, until the bones are sawed through.

When there are two bones, apply the saw in such a manner that both may drop together, to prevent making splinters, and also to avoid the painful jar which the patient feels when this is neglected. While the saw is working, the assistant who holds the lower part of the limb should gently depress it, that the saw may have room to pass; and the operator should make his strokes with it as long as possible.

If, after amputation, the larger arteries are not easily seen, the tourniquet may be slackened, and by the discharge of blood they will be discovered; then with the curved needles secure them, as directed in wounds of the arteries. When the tenaculum can be used for

drawing out the artery, it will always be the best method; and, having so done, tie the end of the artery with a narrow flat tape. If an ossified artery is cut through, a cautery, either actual or potential, must be applied. In the fore-arm, compresses generally suffice for checking the hæmorrhage.

When the arteries are secured, bring the skin over the end of the bone as far as possible; then apply a pledget of soft lint, and over it another of soft tow, or more if required; over these lay a pledget of tow spread with the common cerate, and then with two long slips of sticking plaster, placed across each other, confine the whole by fixing the ends of these slips along the sides of the stump; after this finish the dressing, by turning a worsted night-cap over the whole. It is properly observed by some surgeons, that dry lint, as an extraneous body, in which light it should be considered, and as which it always acts, when clotted with blood, occasions pain, swelling, and inflammation, therefore should be laid aside, and in its place a large quantity of flour should be strewn over the whole stump. This forms a natural cataplasm with the blood and serum. Over this apply dry lint, or what other dressings you like, which may all be removed the next day, if necessary, without pain to the patient, or trouble to his assistants.

The custom of finishing by a roller from below upward, or indeed any way applied, is now omitted by the ablest surgeons, as its pressure causes inflammation, pain, and sanies, instead of a well digested matter.

In the 2d vol. of the London Medical Obs. and Inq. Mr. Kirkland proposes the use of sponge for a part of the dressing, as soon as digestion is begun in the stump, after an *amputation*. He observes, that the greatest danger after this operation, is from an absorption of the matter from the wound after the inflammation is gone off, particularly if the digestion proceeds not very kindly; and to prevent this inconvenience, as soon as the state of digestion is well advanced, he directs a thin layer of fine lint to be applied to the stump, and, immediately upon that, some thin pieces of fine sponge, which have just then been made wet, but are squeezed as dry as can be by the grasp of the hand. The thinner matter of the discharge from the wound being absorbed by the sponge, the fever, diarrhœa, and other symptoms which it occasions when taken up into the circulation, are prevented; and where, from the thinness and acrimony of the discharge, sponge pledgets are necessary, he orders antiseptic diuretics to be administered internally, and, if needful, the bark.

When the dressing is finished, the patient should be laid in bed, and an assistant should gently and constantly hold his hand on the stump during some hours, not only to guard against a hæmorrhage, but also by the gentle pressure to make the dressings adhere more firmly.

The tourniquet may be gradually raised to admit the circulation of the part more freely; and if no danger seems to threaten, it may be removed the next day.

As soon as the patient is in bed, some blood, to prevent a fever, may be taken in plethoric habits.

On the third or fourth day remove the dressings, and proceed as in a common wound. If any part of the lint adheres, leave it to separate by digestion.

The *amputation* of the arm, and of the fore-arm, are

the same, except that in the fore-arm the brachial artery, dividing into branches, sometimes demands the use of the needle, more than when the operation is in the arm. In general, when the arm is amputated above the elbow, the same procedure will be necessary as is directed for the *amputation* of the thigh just above the knee.

See Bell's Surgery, vol. vi. 425. White's Surgery, 200, 201, 202.

#### *The AMPUTATION of the ARM at its JOINT with the SCAPULA.*

Mr. Morand, the elder, first took off the arm at the shoulder, and Mr. Bromfield performed it with success in London. Here the tourniquet cannot be applied; but Dr. Hunter observes, that, when we consider the situation of the blood vessels as they pass over the first rib to the arm, it evidently appears, that by turning the shoulder outwards, and making a proper pressure with compresses, we can check the circulation in amputating the humerus, at its articulation with the scapula, which is the most intimidating circumstance in the operation.

The patient's arm being held horizontally, make an incision through to the flesh, from the upper part of the shoulder, across the pectoral muscles, down to the armpit; and, to save as much skin as you can, begin it about two inches below the joint, then turning the knife with its edge upwards, divide that muscle, and part of the deltoid. The great artery and vein are thus exposed, and should immediately be secured by ligatures, at least two fingers' breadth below the axilla. For this purpose, carry the arm a little backward; then divide these vessels at a considerable distance below the ligatures, and pursue the circular incision through the joint, cutting first into that part of the bursal ligament which is nearest to the axilla; for, by beginning on the upper part of the shoulder, the projection of the process acromion, and processus coracoides, will very much embarrass the operation. Having discovered the true situation of the acromion, draw back the skin, and in dividing the flesh introduce the knife two or three fingers' breadth under it, for much of the deltoid muscle is thus saved, which will fill up the wound, and expedite its healing. Then raise the arm, that the head of the biceps muscle may be more easily found and divided; divide the ligament on the upper part, next on the sides, after which, the head being lifted out of the socket, cut away all that detains it, taking care not to divide the artery above the ligatures. The remaining flesh at the arm-pit should be nearly of a triangular figure, the broad part being next to the axilla. Apply the remaining flesh immediately to the socket of the scapula, and lay over them dry lint and pledgets, which may be secured by a plaster of the shape of a Maltese cross. To prevent the force of the artery, lay a bolster in the arm-pit, to press upon it; secure the whole with the bandage called the *spica descendens*.

See Bell's Surgery, vol. vi. p. 417.

#### *AMPUTATION of the BREAST.*

The patient being placed on a high chair, hold her arm horizontally backward, and a very little downward; thus the pectoral muscle is more expanded, and the disordered part more easily separated from it; then make

a circular incision through the teguments, and dissect out the morbid part. The compress and bandage are generally sufficient to prevent hæmorrhages, the needle being seldom required; though the branches of the mammary arteries, especially one larger than the rest from towards the arm-pits, near the edge of the pectoral muscle, will be sometimes troublesome. The management in other respects is the same as in wounds in general.

If, in the course of the cure, a fever comes on, with pains about the præcordia, and a difficulty of breathing, death is the consequence. Proper and timely bleeding may prevent these symptoms. Bell, vol. ii. 434.

#### AMPUTATION of the FINGERS and TOES.

Sometimes a finger or toe that is nearly cut through with a sharp instrument, if brought together while warm, will unite; at least it is better to make the attempt. When cut obliquely, their re-union may be more certainly expected.

The fingers and toes are best amputated in their articulations; a straight knife must be used, and the incision of the skin should be made not exactly upon the joint, but a little towards the extremity of the finger or toe, that more of it may be preserved for the easier healing afterwards: it will also facilitate the separation of the joint, when the finger is cut from the metacarpal bone, to make two small longitudinal incisions on each side of it first. When the lower joints are separated, the first incisions should be from a little above, to a little below the joint on each side, and so deep as to divide the ligaments. The skin grows over the cartilage very readily. If the cartilage is removed by the knife's point, or by any accident, the skin heals better, and unites speedily to the bone; but this is not necessary. If the patient is plethoric, let the blood run from the amputated joint, and no hæmorrhage will happen thereafter. It is never necessary to take up an artery.

In case of supernumerary fingers or toes, if troublesome, cut them off: sometimes there is no bone where they are to be cut off; in this case a knife may be used: but if there is any bone, a strong pair of scissors may be used, for in infants these bones are not hard.

See Bell's Surgery, vol. vi. p. 411. White's Surgery, 199.

#### AMPUTATION of the HAND.

Heister thinks it best to amputate the hand with a knife only, at the joint of the wrist; but the usual method is to cut through the bones above the wrist: in which case, see AMPUTATION of the ARM.

#### AMPUTATION of the METACARPAL and METATARSAL BONES.

If any of these bones are carious, only so much as is disordered may be separated; a small spring saw is the most proper to divide the bones. After these operations, the parts heal soon, and a part of a hand or foot may still be useful.

In these cases carry your knife first along the side of the bone that is to be removed, and as close to it as you can, at the same time making the wound as smooth as possible. If one of the middle bones is to be removed, we must of course make two incisions, one on each side: having done this, divide the integuments from the

bone above and below transversely, then scrape off the periosteum, and saw through the bone with the saw called the metacarpal saw. Hold the saw very steady, and make long strokes when using it. If two bones are to be removed, we should proceed as above in general; also remember to divide the integuments, &c. transversely between the two bones, as is done between the tibia and fibula, or between the radius and ulna, in amputations of those parts. As in amputations of the fingers and toes, so in this case, the tourniquet is not required.

White's Surgery, 300.

#### AMPUTATION of the LEG.

If the leg is to be amputated, though the injury is ever so near the ankle, as a long stump is thought more inconvenient than a short one, it is preferred to amputate about four or five fingers' breadth below the tuberosity of the tibia; if it is cut higher, the aponeurotic expansion of the flexor muscle will be hurt; besides, the stump would be too short for an easy support on the wooden leg; and an artery which runs into the thickness of the tibia to be distributed to the marrow, would be unnecessarily wounded.

As the gastrocnemii muscles draw back the skin more strongly than it is drawn elsewhere, it is proper, in order to keep the skin equal after the operation, to cut so that the wound on the calf of the leg is further from the middle of the ham, than the wound in the fore part is from the middle of the patella.

In amputating the upper limb and the breast, a chair is the properest to place the patient on; but for the lower limbs, a table about two feet and a half high is to be preferred.

The tourniquet must be placed three or four inches above the patella, and so as to press more particularly on the artery in the ham. The slips of plaster directed in the amputation for guiding the knife, must be placed four or five fingers' breadth below the patella; and the operator must stand on the inside of the leg, because the fibula will then be sawed at the same time with the tibia: but if, on the contrary, the saw is laid on the inside of the leg, the tibia will be first divided, and the fibula, being too weak to bear the force of the saw, will be apt to splinter, so not only render the operation tedious, but also the cure more difficult afterwards.

Though the practice of making a short stump hath so generally obtained, Mr. White prefers amputating betwixt the calf of the leg and the ankle, in cases that will admit of saving so much of the leg; he gives instances of his practice this way, and assures us, that the motion of the long stump is more easy than that of the short one.

After the separation of the limb, the dressing and general treatment will be the same as in amputation of the arm. See Medical Obs. and Inq. iv. 168. Bell's Surgery, vi. 374. White's Surgery, 204.

#### AMPUTATION of the PENIS.

If a cancer, or a sphacelus, in consequence of a scirrhous gland, should appear in the penis, then every part to which the contagion had reached is speedily to be extirpated, lest the taint be diffused further.

Some cut off the penis with a knife; see Le Dran's

Operations: but the following method is to be preferred.

Pass a small tube of lead, or of silver, into the urethra, a little further than the affected part; then with a silken thread make a ligature upon the sound part near to that which is diseased; make this ligature tighter every day until the latter falls off. See Bell's Surgery, i. 538.

#### AMPUTATION of the THIGH.

In this operation on the lower part of the thigh, the first incision is to be made a little more than two inches above the patella.

The tourniquet must press upon the crural artery, on the upper and inner part of the thigh, where the head of the vastus internus muscle and the triceps meet.

In amputating above the knee, we are advised to cut down to the bone at once; but as there is a great thickness of the skin and flesh, it is almost impossible. However, in cutting, we should remember that the stump should be of a conical form. In this case it is of no consequence on which side of the bone the operator stands. It frequently happens in amputating the thigh, that the flexor muscles contract more than the extensors; so that the patient's knee should be kept slightly bent while cutting through the latter, and extended during the incision of the former. This will produce a more convenient stump, without adding to the patient's pain. Perhaps it may be still better, according to Richter, to divide the extensors higher, and the flexors lower; or, which amounts to the same, in the relative positions just mentioned. Mr. Allanson recommends scooping out the flesh in the form of a truncated cone, but this greatly increases the pain without any adequate advantage; nor, according to Richter and Mursinna, is it easily or usefully practised. However the operation is performed, the skin that is preserved is brought together as nearly as its size will permit, and, as much as possible, joined by the adhesive inflammation.

When *amputation* is performed on this limb, the muscles, not being attached to the body of the bone, frequently retract; this never happens in the arm, and may be remedied by placing the patient on his side, and keeping the muscles in as relaxed a state as possible. The method of amputating with flaps was first invented to remedy this inconvenience, which hath occasioned the contrivance of a new mode of amputating, by Mr. Allanson, of Liverpool. He first makes an incision through the skin, then dissects a sufficient quantity of it from the muscles to cover the stump; divides the muscles down to the bone, where he finishes the dissection, and then saws through the bone at the same place, in the usual manner. He afterwards takes up the vessels with the tenaculum, brings the skin over the stump, leaves the ligature hanging out at the external orifice, and applies no kind of dressings except something to cover it superficially.

After the operation, the roller that is to keep down the skin should go round the waist, and descend down the thigh to the stump: thus abscesses are prevented, which otherwise would form themselves on the upper part of the thigh. It has been recommended in *amputations* of this limb, to dissect away the cellular substance, as this has been thought to produce all the sup-

uration and discharge: it hath been tried, indeed, and with seeming success: but others omit this part of the operation, and think the cellular membrane is a convenient cushion for the stump to rest on.

Another circumstance deserving attention is, after the operation, to press the crural artery the whole length of the thigh by a long bolster.

The operation has been sometimes performed with a double flap; that is, a portion of the skin is preserved from above and below. This mode of performing it has not yet become general; yet our experience hitherto is in its favour. One inconvenience attending the operation with one or two flaps is, the hæmorrhage sometimes ensuing, which has induced Mr. Halloran to propose our not attempting the union till the suppuration has come on, both in the stump and the internal surface of the flap. They are then applied to each other with more advantage.

If the operation is made on the upper part of the thigh, the danger is very great; the discharge from the wound when it digests being so copious, that the patient's strength soon sinks, and death is a speedy consequence. If *amputation* in the upper part of the thigh be necessary, it would be best performed in the articulation; for then the crural artery would be better secured, and many other inconveniences avoided which attend in the usual method; but in the most desperate circumstances, taking off the thigh at the articulation is not yet encouraged. Bell's Surgery, vol. vi. 338. White's Surgery, 201.

This Herculean operation has been practised with, at least, *promise* of success, by Mr. Kerr of Northampton, (Duncan's Med. Com. vi. 337); yet we suspect the danger must be very imminent to lead to a similar trial.

The boldness of modern surgeons has, however, gone one step further. Mr. Park has proposed, in cases where an accident, or a swelling of the joint of the knee or the elbow, rendered amputation necessary, to saw through the bones near the joint, on either side of the articulation, and unite the disjoined ends by a callus, as a stiff joint was preferable to the loss of a limb. He admits, that it may be of less use in scrofulous swellings than in cases of fracture near the joint. We have, however, no instance of a follower of this intrepid example; though we think the attempt much more justifiable than some others which we shall have occasion to record.

A German surgeon, M. Wrabetz, proposes amputating without the knife. A cord is to be macerated in a strong vesicating ointment; and, after retracting the skin, to be tightened round the limb. The crevice which it makes is to be filled with an astringent and antiseptic powder, and the patient supported with tonics and cordials. The cord must be kept constantly tight till it reaches the bone, which we suppose must be then sawn off, though this is not mentioned.

See Sharpe's Operation of Surgery, ch. xxxvii. Sharpe's Critical Enquiry, ch. vii. Heister's Surgery. Le Dran's Operations. Bilguer's Dissertation on Amputations. A Complete Treatise on the Gangrene and Spæcelus, with a new Method of Amputation, by Mr. O'Halloran. Allanson's Practical Observations on Amputation. Mynors's Practical Thoughts on Amputations, &c. London Med. Journal, vol. i. 231. Bell's Surgery, vol. vi. 301. White's Surgery, 190.

AMPUTATURA, (from *amputo*, to cut off). A wound from the entire separation of a part from the body.

AMU'CTICA, (from *αμύττω*, to vellicate). Remedies that by vellicating and stimulating the bronchiæ raise a cough, and so contribute to the discharge of what is in the lungs. They are given to relieve disorders of the voice, and the aspera arteria; and are also called *arteriaca*.

AMULE'TA, (from *αμύα*, a band, because it was tied round the person's neck; or from *αμύνα*, to defend). AMULETS.

Amulets and charms are so nearly allied, as to be considered in the same light. In each, superstition, the common disease of weak minds, is indulged.

Sometimes words, *ἐπιδίδωμι*, or *carmina*, were written and carried by the patient on some part of his body, or in some of his garments. These were called AMULETA, from *amovere*, to remove, and PRO'EBIA, or PRO'EBRA, from *prohibere*, to defend. The Greeks call them APOTROPÆA, PHYLACTE'RIA, AMYTE'RIA, ALEXITE'RIA, and ALEXIPHA'RMACA, because they imagined that these remedies could defend them, not only against such diseases as proceed from natural causes, but also against the power of other enchantments.

These amulets were formed of any materials which fancy suggested.

Serenus Samonicus invented the ABRACADA'BRA for the cure of the fever called hemitritæa. The Jews attributed the same virtue to the word ARA'CALAN. The Arabians were anxious to see if the stars favoured them, and call it TALISMA, i. e. IMAGE.

Amulets tied about patients for the removal of disease were called PERIA'PTA, and PERIA'MMATA, from *περι*, circum, and *ἀπ'ω*, necto. Blanchard says that they are medicines which, being tied about the neck, are believed to expel diseases, especially the plague. The royal touch was ridiculously said to cure the king's evil.

Charms seem to have imposed a belief, that those who were exercising them were particularly favoured by some superior being. This gave the world a venerable idea of the practitioner; and as the mind affects the body, the persuasion of the patient might sometimes contribute to a cure.

Yet it has happened that this supposed amulet may have some virtue. We mean not to allude to quills of quicksilver and arsenic worn about the neck, the ecl-skin tied about the legs to prevent cramp, or the stones worn against hæmorrhages; but the essence vessels hung round the neck, the *καρδιοφυλάκα* of the Greeks, if filled with any very volatile aroma, may have been useful in guarding against contagion. Even the camphor, if not too closely confined, may have some effect; and we remember being told by a former recorder of London, that he found it imparted some warmth. The aromatic vinegar and the attar of roses diffuse a very sensible perfume, however closely shut up; and M. Morveau's antipestilential box, which contains ingredients that, on the access of the atmosphere, act on each other, producing a copious exhalation of pure air, though as an external appendage it may rank with amulets, must have a certain and powerful effect.

AMU'RCA (from *αμύργω*, to press out). AMORGE

and BYSMA are probably the same. It is the sediment from olive oil, found after the newly pressed oil hath deposited its gross contents.

AM'YCHE, (from *αμύσσω*, to scratch). A superficial exulceration, or scarification of the skin.

AMY'CTICA. STIMULATING, VELLICATING. See AMU'CTICA.

AMY'GDALÆ, (*αμυγδαλον*, almond,) ALMONDS. The fruit of the AMYGDALUS, ALMOND TREE. A *communis* and *nana* Lin. Sp. Pl. 677.

AMY'GDALÆ AMA'RE. BITTER ALMONDS.

AMY'GDALÆ DU'LCES. SWEET ALMONDS.

The leaves and flowers of the almond tree resemble those of the peach tree, a species of the same genus, *a. persica* Lin. Sp. Pl. 676. It is a native of Africa, and flowers earlier in the spring than most other trees, though its fruit is not quite ripe until autumn.

Of the fruit we have two sorts, the sweet and the bitter; which are varieties, only changing these qualities with the soil. It is the *amygdalus communis* Lin. Sp. Pl. 677. The almonds from Barbary, where the tree is indigenous, are bitter, while those cultivated in Europe are sweet.

The bitter matter resides in the mucilage, and dissolves with a little heat in water and in spirit of wine: a part arises with both in distillation; but spirit seems to extract, and water to elevate, the greatest quantity. A simple water may be distilled from them after the oil is pressed out, possessing the same qualities as that drawn from cherry stones. It is not, however, at present employed. The flavour, when required, is obtained from peach or laurel leaves.

The distilled water of bitter almonds is strongly impregnated with the noxious matter which gives them their bitterness and flavour. It seems by some late experiments to consist of the *Prussic acid*, and may prove a poison, as is the case with the common laurel, to which it appears extremely analogous. Four or five bitter almonds are commended as anthelmintic, taken in a morning fasting: they are said to be diuretic, but occasion sickness and vomiting; to dogs, foxes, fowls, storks, horses, especially while very young, to pigeons, cats, and some other animals, they are poisonous.

The sweet kind should be chosen free from rancidity; and, if in the shells, from all appearance of insects, a species of which penetrates them, and destroys the kernel. They digest with difficulty, and afford very little nourishment, unless extremely well comminuted. As a medicine they obtund acrimony in the *primæ viæ*, are softening, and relaxant. They are a good intermedium for uniting with water several substances, which of themselves are not miscible with it: camphor, and many resinous substances, triturated with almonds, easily dissolve into a milky liquor. For this purpose the almonds must be freed from their skin, but it should not be by infusing them in hot water, as this separates the oil. A longer infusion in cold water is preferable. Six or eight sweet almonds peeled sometimes cure the heart-burn; and one or two almonds at most will mix five or six grains of camphor or resin.

Sweet almonds are usually blanched, i. e. freed from their skin, by steeping them in hot water until it easily slips off: then triturated with water, their oil unites therewith, by the mutation of their mucilaginous and farinaceous matter, into an emulsion or milky liquor.

The pure oil of almonds, triturated with a thick mucilage of gum arabic, forms a more permanent emulsion than the milk of almonds of the dispensaries; from which the oil does not separate either on standing two or three days, or on the addition of a moderate quantity of acid. One part of gum, made into mucilage, is enough for four parts of oil. The white of egg, or syrup, with a little spirituous water, will form an emulsion, but less perfect than the gum.

R. Gum arab. pulv.  $\mathfrak{z}$  ss. aq. distillatæ  $\mathfrak{z}$  i. f. mucilago per trituram, et adde ol. amygd.  $\mathfrak{z}$  i. ss. sacch. alb.  $\mathfrak{z}$  ss. postea paulatim adde aq. distillatæ  $\mathfrak{f}\mathfrak{f}$  i. f. emuls. If to this emulsion half an ounce of gum arabic be added, it is called ARABIC EMULSION; if half an ounce of chalk, it is named the ABSORBENT EMULSION; if half a drachm of camphor, it is called the CAMPHORATED EMULSION.

The emulsions partake of the quality of the oil, and are prescribed with the same intentions, particularly relieving heat of urine and the strangury, whether from spontaneous acrimony, or irritating food or medicines.

These emulsions, on standing, throw up a cream, and the whey beneath turns sour. Acids joined to them form curd and whey, as in milk.

The milky solution of almonds in water, though containing oil, may be given in acute and inflammatory fevers, without danger of the ill effects which the oil by itself may produce, since emulsions do not become rancid, or acrid by heat; and in most cases the acescency is rather an advantage in the emulsion.

The expressed oil of almonds is obtained from the sweet or the bitter sorts equally. The oil of bitter almonds was called *metopium*, because the Egyptians used to make an oil in which bitter almonds and galbanum were ingredients; and they named their compound, oil of metopium, from the plant that affords the galbanum: others give the same name to the simple expressed oil of this fruit.

By bruising and pressing the almonds, they afford nearly one half of their weight in oil: by boiling them in water, part of their oil separates, and is collected on the surface; but that obtained by pressure, without heat, is the most agreeable.

As a medicine, this oil is useful *externally*; like that of the olives and linseed, it is used to soften and relax the skin; *internally*, to sheathe acrimonious bile, or other fluids, to relieve a tickling cough, hoarseness, costiveness, or nephritic pains. Oils are given in the form of emulsion, the proportion of two ounces to half a pint of water, and sweetened with half an ounce of some agreeable syrup. Draughts of manna and oil of almonds, at the same time using the common emulsion as the usual drink, are of service in the gravel, and in dysuries. The tenesmus, to which some pregnant women are subject, and which endangers abortion, is most speedily relieved by clysters of it, with a few drops of laudanum. Thebesius thought that he found good effects from almonds in hydrophobia, and Bergius speaks of the emulsion of bitter almonds curing obstinate intermittents after the bark had proved unsuccessful.

AMYGDALÆ, and AMYDALIA. See TONSILLÆ.

AMYGDALATUM. The emulsion of almonds.

AMYGDALOIDES, (from *αμυγδαλον*, almond, and *ειδος*, form,) also COMETES. Thus Oribasius calls

the species of tithymalus, which is named *tithymalus masticus*.

It is a name for the white species of the gum benzoin, and of a stone resembling the kernel of an almond in figure, which is the petrified spine of the echinus marinus, or sea urchin. It is also a name for the *gobius* or *gudgeon*.

AMYGDALO-PE'RSICUM, (from *αμυγδαλον*, and *περσικον*, the peach). The ALMOND PEACH.

AMYGDALUS SIMILIS, GUATIMALE'NSIS. See CACAO.

AMY'LA. Any sort of chemical fæcula.

AMYLI TROCHI'SCI. See BECHICA.

AMY'LUM. AMY'LEON. AMY'LION. (From *α*, neg. and *μυλη*, a mill, because it is made of corn without a mill, or without grinding). It is the fæcula of wheat, and with us called STARCH; named also *amidum*.

It is the purest farina of the wheat, but deprived of its gluten; and made also from potatoes. It was invented in the isle of Chios, and is valued according to its lightness, newness, and smoothness.

Starch is often very useful as a mild glutinous astringent, and, mixed with milk, an excellent aliment in fluxes and catarrhs;  $\mathfrak{z}$  i. of starch dissolved and boiled in  $\mathfrak{z}$  iij. of water, with a little sugar, forms an elegant jelly, of which a table spoonful may be taken every hour. If dissolved in thin gruel, it is lenient, incassating, and of service against sharp defluxions, hoarseness, a dry cough, spitting of blood, diarrhœa, dysentery, internal ulcers, heat of urine, gonorrhœa, &c.

In diarrhœas and dysenteries, when the stools are bloody, and the intestines relaxed, the following far exceeds astringents, or any other kind of clysters:

R. Gelatin ex. amylo.  $\mathfrak{z}$  iv. extract. thebaic gr. iij.

Sp. vini. Gallic. opt.  $\mathfrak{z}$  β vel.  $\mathfrak{z}$  i. m. enem. pro re nata injiciendum.

In spasmodic affections of the neck of the bladder, and in that distressing sense of weight and uneasiness, when, in gonorrhœa, the prostate gland is affected, the former clyster of starch, with opium, is an useful remedy, omitting the spirit.

AMY'ON, (from *α*, priv. and *μυς*, a muscle). A limb so emaciated that the muscles scarcely appear.

AMY'RIS OPOBALSAMUM, and its variety. *Balsamea Gileadensis* Wildenow, 334, vol. ii.

AMY'RIS GILEADE'NSIS. See BALSAMUM.

AMY'RIS ELEMI'FERA, Lin. Sp. Pl. Ed. Wildenow, 495. See ELEMI.

AMY'RIS ZEYLO'NICA, (*gum. elemi orientalis*,) Wildenow, 334.

AMY'RIS AMBROS'IACA, (see AMBERGRISE,) Wild. 335. This species yields an odoriferous balsam from its wounded trunk or branches, a dram of which is taken in red wine, it is said, with advantage in the dysentery. The *a. balsamifera* Wilden. is full of aromatic particles, and the berries have the taste of *balsam cofaibæ*. It is a tree found in the island of Jamaica.

AMYTHA'ONIS, Empl. Amythaon's plaster.

R. Gum ammon. cer. flav. gum bdell. āā  $\mathfrak{z}$  viij. tereb. rad. irid. illyr. gum. galb. āā  $\mathfrak{z}$  xx. m.

ANA, signifies *of each*. Thus take of aloes, frankincense, myrrh, ā or āā (that is, of each)  $\mathfrak{z}$  i.

ANABASES, (from *αναβαινω*, to ascend). See ACMASTICOS.

ANAB'ATICA, (from the same,) applied to continual fever, when it increases in malignity. See SYNOCHUS.

ANA'BOLE, (from ἀναβάλλω, to cast up). The discharging any thing by vomit.

ANABROCHI'SMOS, (from ἀνα, -sursum, and βροχος, a noose). An operation performed on the hair of the eye-lids, when they are offensive to the eye.

ANABROSIS, (from ἀναβρωσκω, to devour). A corrosion of the solid parts by sharp humours, or any medicine. The same as *diabrosis*; it occasions a discharge of blood, and often happens in the lungs.

ANACAMPSEROS, (from ἀναχαμπω, to bring back; and ερως, love). An herb, supposed to have the power of reconciling lovers or friends if it was but touched. See CRASSULA.

ANACARDIOS ANTIDOTUS THEODORE'TUS. *The Antidote of Anacardium. A divine gift.*

It is a confect made up of many warm ingredients, but without opium.

ANACARDIUM, ANACARDUS, (from καρδια, the heart). A tree in the East Indies, whose fruit resembles the heart of a bird. *Anacardium orientale*, the MALACCA BEAN TREE. *Avicenna germinans* Lin. 891.

It is said that the Indians use the caustic oil of the nuts of this tree to stain their chintz and calicoes, which sets the colours so as not to wash out.

The kernel, like that of the cashew nut, is mild and agreeable to the taste; yields, by expression, an oil like that from almonds, and is equally good as a medicine.

The *anacardium occidentale* Lin. is used only as a dye or stain.

A confect was formerly made of the kernels, called by Messue *confectio sapientium*; and by others, *confectio anacardii*.

ANACATHARSIS. EXPECTORATION. (From ἀνακαθαίρωμαι, to purge upwards). Under this title the effects of emetics, masticatories, sternutatories, &c. are included.

ANACATHARTICA. Medicines producing anacatharsis.

ANACHRE'MPSIS, (from ἀνω, upwards, and χρεμετίζω, to hawk). The hawking up any thing from the lungs.

ANA'CHRON. See ANATRON.

ANA'CLISIS, (from ἀνακλινω, to recline). Hippocrates uses this word to express the reclining posture of the sick. It also means a couch or sick-bed.

ANACLISMOS, (from the same). That part of a chair on which the back of a sick person leans.

ANACELIA'SMUS, (from ἀνα, and κοιλία, venter). A remedy used by Diocles, which seems to have been gentle purging, with a view to relieve the lungs.

ANA-COLUPA. An Indian plant mentioned in the Hortus Malabaricus, whose genus is not determined. Its juice is said to be useful in epilepsies, and to cure the bite of the naja.

ANACOLLE'MA, (from ἀνακόλλω, to agglutinate). It is the same as *frontale*, only that it is always made of agglutinants or drying powders. Junker describes an *anacollema frontale* for stopping bleeding of the nose. See CATAPLASMA.

ANACOMIDE, (from ἀνακοιμίζω, to repair,) to recover a person after sickness.

ANACTORIUM. See GLADIOLUS.

ANACY'CLEI, (from κυκλω, to wander about). Circulators, mountebanks. See AGYRTÆ.

ANACYRIO'SIS, (from ἀνα, and κυρος, authority) Hippocrates, in his treatise on decency, advises physicians to keep up their authority, and the dignity of their profession, which he expresseth by this word.

ANADENDROMA'LCHE, (from ἀναδενδρον, a tree, and μάλαχη, the mallow). See ALTHÆA.

ANADIPLO'SIS, (from ἀναδιπλω, reduplico). A frequent reduplication of fevers. Blancard.

ANADO'SIS, (from ἀναδιδωμι, to distribute). A distribution of the fluids, and consequently a part of nutrition. See DISTRIBUTIO.

ANADROME, (from ἀνω, upwards, and δρεμω, to run). Hippocrates uses this word to signify pains from the lower to the upper parts of the body.

ANÆSTHÆ'SIA, ANAISTHÆ'SIA, (from α, non, and αισθησις, sensio,) also *anodynia*. INSENSIBILITY, or LOSS OF FEELING BY THE TOUCH. A resolution of the nerves occasioning a loss of feeling; generally a symptom of palsy: the same as *stupor*. It is in the *locales, dysæsthesiæ*, of Cullen.

ANAGALLIS, (from ἀνα, and γαλα, milk, because it has the property of coagulating milk,) called also *corchoron, pimpernella, bibinella*, and *æritis*.

The *anagallis* of the Greeks is the *macia* of the Latins. The species used in medicine is the *anagallis arvensis*. Lin. Sp. Pl. 211.

The expressed juice, inspissated to an extract, is pungent, saline, and austere, and any other preparation seems useless: it is resolvent and detergent, and has been given in hydrophobia.

ANAGALLIS AQUATICA. See BECABUNGA. This is an European plant of the same species, and to be collected before the flowers expand. Its taste is acrid and nauseous, and it has been used in powder, in a dose of twenty grains, three or four times a day, in epilepsy and melancholy. Stoll recommends from ʒ i. to ʒ ij. of the extract, in jaundice. If given in infusion, ʒ ij. of the leaves are added to a pint of water.

ANAGARGAL'CTION, } (ἀνα, and γαργαρεω, }  
ANAGARGARI'STON, } thethroat). See GAR-  
GARISMA.

ANAGLY'PHE, (from ἀναγλυφω, to engrave). See CALAMUS SCRIPTORIUS.

ANAGY'RIS, (from *Anagyris*, a city in Attica,) NON FÆTIDA. See CYTISUS ALPINUS.—*Fætida* Lin. Sp. Pl. 534. The smell is rank, and the taste bitter. It is used as a cathartic and emmenagogue.

ANAISTHÆ'SIA. }  
ANAISTHÆ'SIS. } See ANÆSTHESIA.

ANALCES, from α, neg and αλχη, strength). WEAK, EFFEMINATE. Hippocrates uses this word as an epithet for the Asiatic nations.

ANAL'DES, (from α, neg. and αλδω, to increase). NOT INCREASING. Hippocrates applies this word to fruits growing about the river Phasis.

ANALE'NTIA. A species of epilepsy mentioned by Paracelsus. A corruption of the word *analepsia*.

ANALE'PSIA. Johannes Anglicus and Riverius give this name to the species of epilepsy which proceeds from a disorder of the stomach. It is sometimes synonymous with epilepsy in general. See EPILEPSIA.

ANALE'PSIS, (from ἀναλαμβάνω, to recover and regain vigour after sickness). Hence,

ANALE'PTICA. ANALEPTICS. Such remedies

as exhilarate the spirits, and restore flesh and strength. See CARDI'CA and RESTAURA'NTIA.

Dr. Cullen says, they are medicines suited to restore the force of the body when lost, and are sometimes stimulants; but more commonly nutrients. The term he considers as attended with ambiguity, and thinks that it should be rejected.

Besides the nutritious quality of restoratives, they are supposed to have a fragrant, subtle, oleous principle, which immediately affects the nerves, warms and stimulates the whole system. No such principle, however, exists; at least no such has been discovered.

In diseases, the speediest way to restore strength is to remove the causes of debility; but this is not to be done by medicines, which increase only the vital heat; for in convulsions and fevers the motions are very strong, and yet the natural strength is languid. True strength, however, depends rather upon proper aliments, turned into wholesome blood; the only source of firmness and vigour.

Cordial flowers and herbs, musk, ambergrise, oil of cinnamon made into olea sacchara, chocolate, shell-fish, &c. are the supposed *analeptics*; but they are only such as stimulating nutrients.

ANALGE'SIA, (from  $\alpha$ , neg. and  $\alpha\lambda\gamma\sigma$ , *pain*). INDOLENCE, or absence of pain or grief. A state of ease.

ANALO'GIA, (from  $\alpha\alpha$ , *per, by*, and  $\lambda\omicron\gamma\omicron\varsigma$ , *ratio, reason*). ANALOGY. It is the mode of reasoning of things not perfectly known, by comparison with others which are better understood, and drawing conclusions from their similitude. See BOTANICAL ANALOGY.

ANA'LTHES, (from  $\alpha$ , neg. and  $\alpha\lambda\theta\epsilon\omega$ , *to cure*). INCURABLE.

ANALTOS, (from  $\alpha$ , neg. and  $\acute{\alpha}\lambda\varsigma$ , *salt*). UNSALTED.

ANALYSIS, (from  $\alpha\alpha\lambda\upsilon\omega$ , *to resolve*). In chemistry it is the term used for decomposing any mixed body, and reducing it into its constituent parts. The chemists make use of two modes of analysis: 1. by fire; 2. by menstrua. Indeed the modes of decomposing bodies are all founded on the difference of the properties belonging to the various principles of the body to be analysed. Suppose, for instance, a body to be composed of several principles, possessed of different degrees of volatility, the volatile parts will rise in proportion to the degrees of volatility which they possess on the application of heat; and if any are fixed, they will remain in the retort or crucible. This is called ANALYSIS BY FIRE. But when a body is compounded of several substances, one of which, for instance, is soluble only in spirits of wine, a second in water, and a third in æther, these substances may be very easily separated from each other, by submitting successively the compound to the action of these menstrua. This is called the ANALYSIS BY MENSTRUUA. See, on this subject, Macquer's Chemical Dictionary; Memoirs of the Royal Academy of Sciences, for the years 1719, 1720, 1721; Elements and Principles of Chemistry, by Lavoisier, Fourcroy, Chaptal, and Thomson.

In anatomy, the dissection of the human body is called ANALYSIS.

ANAMNE'STICA, (from  $\alpha\alpha$ , and  $\mu\eta\alpha\sigma\mu\alpha\iota$ , *record, to remember*). Medicines supposed to improve the

memory, or restore it when lost. We need not add, that the power of such medicines is imaginary.

ANAMNE'STICA SIGNA. COMMEMORATIVE SIGNS: signs which discover the preceding state of the body: as demonstrative signs shew the present state; and prognostics shew the future state.

ANA'NAS. The Brasilians call it *yayanna*. The PINE APPLE. The *bromelia ananas* Lin. Sp. Pl. 408: called also *carduus Brasilianus*.

Mons. Le Cour, of Leyden, was the first who raised this fruit in Europe: they were brought from the East Indies to the West, and from thence into Europe. It resembles the cone or fruit of a pine tree, and from thence takes its name; the richness and the flavour of the fruit are well known. It is, however, cold, watery, and indigestible. See ALIMENT.

ANA'NAS, WILD. See KARATAS. *Bromelia karatus* Lin. Sp. Pl. 408.

ANA'NDROI, (from  $\alpha$ , non, and  $\alpha\upsilon\gamma$ , *vir*). Hippocrates applies this word to women who have never known men.

ANA'PALIN, (from  $\alpha\alpha$ , and  $\pi\alpha\lambda\iota\nu$ , *rursus*). On the contrary side; as if nature endeavoured to free herself from some disease, by her exertions on the side opposite to that wherein the affection arose. It is opposed to CATI'XIS, which see.

ANAPHALANTI'ASIS, (from  $\alpha\alpha\phi\alpha\lambda\alpha\upsilon\tau\omicron$ , *a bald person*). Baldness of the eye-brows.

ANAPHONE'SIS, (from  $\alpha\alpha$ , and  $\phi\omega\eta$ , *vox*). A species of exercise which consisted in vociferation.

It is supposed to increase the natural heat, improve the appetite and digestion, and to be useful to the phlegmatic and cachectic. Singing is a gentler exercise. See Hieron Mercurialis De Arte Gymnasticâ.

ANA'PHORA, (from  $\alpha\alpha\phi\epsilon\rho\omega$ , *to bring up, or upwards*). Hippocrates uses it for thanks due to an obligation. Any discharge from the mouth.

ANAPHO'RICOI, (from the same). Those who spit blood; or, according to Actuarius, those who spit with difficulty.

ANA'PHRA, (from  $\alpha$  neg. and  $\phi\epsilon\omicron\varsigma$ , *froth*). Hippocrates uses it as an epithet for stools that are not frothy.

ANAPHRODI'SIA, (from  $\alpha$ , neg. and  $\alpha\phi\rho\omicron\delta\iota\sigma\iota\alpha$ , *venery*), called also *agenesia*; *atechnia*. IMPOTENCE WITH RESPECT TO VENEREAL COMMERCE. In the *locales*, *dysorexia*, of Cullen.

This disease arises from a deficiency of semen, or a weakness of the muscular powers necessary to its effectual discharge. In some instances, the semen itself seems defective in its essential qualities. Sauvages has given us five species, which Dr. Cullen thus divides. The *true species* are the paralytic and gonorrhœal; the *spurious species*, where impediments occur to prevent the act, from piles, or some fault in the urethra; *what is called false or fictitious*, supposed to arise from magic. See Sauvages, vol. i. 770.

The cure of this disease depends upon the removal of its separate causes. Sauvages gives us an account of a man being cured by immersing the penis often in the day in a strong decoction of mustard seed. If it is occasioned by weakness or a simple gonorrhœa, such aids are to be called in as are calculated to invigorate the system; tonics and corroborants are to be made use of.

particularly cold bathing, avoiding high seasoned foods and cordial stimulants. No error is more common or more pernicious than indulging highly nourishing food in such instances; for there is no more frequent cause of debility than over distended vessels. If from the piles, or faults in the urethra, these complaints must be combated by the appropriate remedies.

ANAPHROME'LI, (from *a* neg. *αφρος*, froth, and *μελι*, honey). It is honey so despumated that it will not froth.

ANAPLA'SIS, (from *αναπλασσω*, to restore to the original form). Hippocrates uses this word for the accurately replacing and restoring a fractured bone, and for a restoration of flesh. It is synonymous with DIAPLASIS.

ANAPLERO'SIS, and ANEPLERO'TICS, (from *αναπληρωω*, to fill up). The restitution of any wasted part. INCARNA'TIA, incarnatives, are called *anaplerotica*. The same with PROSTHESIS.

ANAPLE'USIS, (from *αναπλεω*, to wash out). When faulty humours rot the bone so that it falls out of its joint, as happens sometimes in the jaw, this term is employed by Hippocrates. In Vogel it implies the scaling or separation of the carious parts of a bone.

ANAPNEU'SIS, (from *αναπνεω*, to respire). RESPIRATION, PERSPIRATION. Aretæus uses it to express a truce from pain.

ANAPODOPHYL'LON, (of *anas*, a duck, *πους*, a foot, and *φυλλον*, a leaf). DUCK'S FOOT; so called from its resemblance; or *homum Maiale*, MAY APPLE: called also *podophyllum peltatum*, *aconiti folia*, Lin. Sp. Pl. 723. The Americans call it BLACK SNAKE ROOT. It bears the hardest winter in an open ground, and is increased by parting the root in August.

ANAPSY'XIS, (from *αναψυχω*, to make cold). REFRIGERATION, i. e. cooling.

ANAPAPHE, (from *ανα*, and *ραφη*, suture). It is the suture and retraction of the upper eye-lid, when relaxed, (*sutura blepharica suspensis, collectio et brevisatio, superioris palpebræ*). It is employed not only in relaxation of the palpebra, but where the hairs are thick and long.

ANARISITE'SIS, (from *a*, neg. and *αριστον*, a dinner). Hippocrates uses this word for the subtraction of a dinner from a patient.

ANARRHI'NUM, (from *ανα*, and *ρις*, a nose). See ANTIRRHINUM.

ANARRHŒ'A, (from *ανα*, upward, and *ρεω*, to flow). A flux of humours from below upwards.

ANA'RTHROI, (from *a*, neg. and *αρθρον*, a joint), fatness so considerable as to obliterate the joints.

A'NAS. The DUCK. See A'NSER.

ANASA'RCA, (from *ανα*, through, and *σαρξ*, flesh,) called also *catasarca*, *episarcidiam*, *intercus*, *Pituita alba*, *hyposarca*, *hyposarcidies*, *veterum hyderos*, *Galenii phlegmatia*, *phlegmatitia*. A species of DROPSY from a serous humour between the skin and flesh; or rather a general accumulation of lymph in the cellular system. It occurs in the class *cachexia* and order *intumescentie* of Cullen, and he enumerates the following species, viz.

1. ANASA'RCA SEROSA, from serum, retained on account of the suppression of some accustomed evacuations; or from an increase of serum from too much water thrown into the habit, from too large a proportion of neutral salts.

2. ANASA'RCA OPPILATA, when the veins are considerably pressed, which happens to many pregnant women, &c.

3. ANASA'RCA EXANTHEMATICA, after cruptive disorders, and particularly after the erysipelas.

4. ANASA'RCA ANEMIA, when the blood is rendered extremely poor from considerable losses of it.

5. ANASA'RCA DEBILIUM, in weak constitutions.

An œdema, in any part, hath the same appearance as the *anasarca*, but it is partial; a leucophlegmatia is general; and an *anasarca* is the worst state of the leucophlegmatia.

Its seat is the cellular membrane; if only one limb, or a particular part, hath its cellular membrane filled, it is called an ŒDEMATOUS SWELLING.

It is known by the sight and the touch; the skin of the part is considerably swelled, its colour is paler, and upon pressing it deeply with a finger the impression remains some time: if the belly is affected, the navel appears to be sunk in, and in a morning the eye-lids, or the whole face, appear fuller than in the latter part of the day.

The occasional causes are, scirrhus glands, cachexy, suppression of periodical evacuations, and every cause that will impoverish the blood and debilitate the system. The more immediate causes are, a defect of red globules in the blood, an increased action of the exhalant arteries, or a want of power in the absorbent vessels into the cellular membrane.

Persons recovering from lingering diseases are very subject to this complaint, particularly if they replenish their weak vessels too fast by full diet. Exposure to cold and damp air, particularly in the night, from the check it gives to the natural discharge by the skin, late hours, too tight ligatures on the legs, scirrhusities and obstructions in the liver or other viscera, dispose to and produce either general or partial *anasarca*. For the cure of this complaint see DROPSY.

Scarifications with a knife are much commended when the legs and thighs are turgid with extravasated serum; and, indeed, the water is speedily discharged this way; but the lips of the wound will close in two days, so as to admit of no discharge; and from a defect of heat in the constitution, the part is apt to mortify. To obviate these difficulties, Dr. Fothergill advises this operation to be performed with the common scarificator used in cupping, and the instrument to be placed so as to make the wounds transversely: if the skin is thick, the lancet may be so set as to make deeper, and consequently wider, incisions: thus a large quantity of water will often drain from the legs or thighs without risk of inflammation, or deterring the patient from a repetition, if necessary. The punctures must be made in the most depending part of the leg; and their number and repetition depend on the circumstances of each individual case. The application of glasses, either before or after scarifying, is unnecessary; but the instrument must be gently pressed upon the skin, until a surface is formed sufficiently flat to admit the lancets in the scarificator to act equally. In all cases where the skin is so stretched as to threaten inflammation, rupture, or a gangrene, and when the breath is greatly impeded, these openings should be made without delay. Blisters are often employed in the same circumstances instead of scarifications, and are equally useful. In some respects

they are of superior utility, as the discharge can be continued for a longer period, and the increased surface admits of the evacuation of a larger quantity of fluid. An oblong blister may be applied just above the inner angle, and continued till a thick white or purulent discharge is produced. After this period but little water appears, and the sore should be healed. If necessary to be longer continued, blisters may be employed on the outside; and, when these have acted sufficiently, we may return to the former surface, which will be now healed. Apprehensions have been entertained of gangrene following the application of blisters in this way. No such inconvenience has, however, occurred to us in a long practice; and should a little black spot appear, a warm antiseptic fomentation, and sprinkling the spot with the powder of myrrh or of oak bark, has always separated it. We must add, that not only in this, but every species of dropsy attempted to be cured by internal means, however they may be relieved by different evacuations, unless the urinary organs continue their evacuating power, the cure will never be lasting. See Lond. Med. Obs. and Inq. vol. iv. p. 120, 122. Dr. Leake's Medical Instructions, edit. v. Cullen's First Lines, vol. iv. edit. iv. Le Dran's Operations, edit. ii. p. 113—116. The London Practice of Physic, edit. v. Bell's Surgery, v. 499. Wallis's Sydenham on the Dropsy.

ANASPA'SIS, (from *ανα*, and *σπασω*, to draw). A contraction of the stomach. Hippocrates.

ANA'SSUTOS, (from *ανα*, upwards, and *συνω*, to move). Hippocrates, when speaking of the suffocation observed in hysteric fits, and the air rushing out with violence upwards, employs this epithet.

ANASTALTICA, (from *αναστελλω*, to contract). See ASTRINGENTIA.

ANA'STASIS, (from *αναστημι*, to cause to rise). A rising up to go to stool; also a migration of humours, and a rising up or recovery from sickness. Hippocrates.

ANASTOICHEIO'SIS, (from *ανα*, and *στοιχειον*, a principle or element). A resolution of a body into the elements of which it was composed: a colliquation or dissolution of the solids or fluids of the body.

ANASTOMO'SIS, (from *αναστομω*, or *ανα*, per, and *στομα*, a mouth; also *axanastomosis*, *inoculatio*). Anatomists use the word to express the inoculation of the arteries and veins, or their running into one another. The menses, discharged, are said to be discharged by *anastomosis*, i. e. by the opening the mouths of the vessels into the uterus.

If the blood transudes through the sides of the vessels, the discharge is said to be *per diapedesin*, transudation.

If the vessels are corroded by acrid humours, the discharge is *per diabrosis*, erosion.

ANASTOMO'TICA, (from the same). Medicines suited to open the mouths of the extreme blood vessels; sometimes of the same import with *aperientia*.

ANAT. The abbreviation of *Anatomica*.

ANA'TES, (from *nates*, the buttocks). A disease of the anus.

ANA'THRON. A salt which vegetates on rocks in the form of white stony moss. It is the FOSSIL ALKALI.

ANATHYMI'ASIS, (from *θυμιαω*, to fumigate). See EVAPORATIO.

ANA'TICA PROPO'RTIO, (from *ana*, equal). EQUAL PROPORTION.

ANATO'MIA, *ανατομη*, (from *ανα*, through, and *τεμνω*, to cut, or from *ανατεμνω*, to dissect).

*Anatomy* is the art of dissecting the human body in order to demonstrate the shape, structure, connexion, and situation of the parts; this, though it does not teach the remedies of a disease, leads us to understand the situation of the diseased part, and the influence of the disease on the functions. In short, whatever perfection the art of healing might have arisen to by the aid of practical experiments and observation, it cannot be denied that its greatest lights were received from *anatomy* and physiology. To know the peculiar structure of each part, its use, what functions it performs, what connexion it hath with other parts, and influence on them, whether near or remote, are advantages too obvious to be denied.

The sympathy of the nerves leads us to distinguish many diseases, the seat of which is in one part of the body, whilst a very distant one is the part complained of. The intercostal branch, and the eighth pair of nerves, run almost all over the body.

Hippocrates, though he only once had the opportunity of viewing a human skeleton, yet used every method in his power to inform himself in this branch of his art, and hath left behind a tolerably good description of the human bones.

After Hippocrates, succeeded Alcmaeon of Crotona, Aristotle, Herophilus, Erasistratus, Aretæus, Praxagoras, Galen, Oribasius, Nemesius, Mundinus, Alexander Achilinus, Guido de Cauliaco, Jacobus Berengarius Carpensis, Nicolaus Massa, Andreas Vesalius, Jacobus Sylvius, Michaelis Servetus, Realdus Columbus, Ambrosius Paræus, Bartholomæus Eustachius, Volcherus Coiter, Andreas Cæsalpinus, Hieronymus Fabricius ab Aquapendente, William Harvey, Theophilus Bonetus, William Cooper, James Douglas, Clopton Havers, Marcellus Malpighius, Nathaniel Highmore, Anthony Nuck, Pecquet, Monro, sen. Morgagni, Needham, Nicholls, Ruysch, Steno, Winslow, Cheselden, the two Hunters, the second Monro, and many others, who, as physicians, surgeons, or both, did honour to their profession.

The first anatomical publication in the English language was, The Englishman's Treasure, or the true Anatomy of Man's Body, by Thomas Vicary, Surgeon in London. It was printed and reprinted three or four times between the years 1548 and 1633.

It is the advice of the greatest anatomists, that authors on this subject should not be read before an acquaintance with the parts is, in some degree, obtained by seeing bodies dissected; previous to dissection, books rather retard than facilitate the progress. When, by seeing all the parts demonstrated and their uses explained, the student hath a clear idea of them, reading will be necessary, both to fix the impression on the mind, and to inform him of different opinions and disputed points, which he will now be in some degree able to appreciate and determine.

Those whose circumstances do not favour their attendance on dissection, may acquire a good general knowledge of the *anatomy* of a human body from Cheselden's work, which is still an excellent introduction; and Bell's Anatomy, in three volumes octavo. Winslow's Anatomy seems best calculated for the attention of those who have already been familiar with dissections, and the demonstrations given by able ana-

tomists; but one of the most useful works for students is a System of Anatomy and Physiology, published at Edinburgh, 1791.

The Anatomical Tables of Albinus, Eustachius, Jenty, and Cooper, should be attended to. Bell's plates of the bones and muscles are indifferently executed: those of the vessels and nerves in a superior manner.

Several parts of the human body, particularly the internal, are excellently delineated in Haller's Icones; and the brain very minutely and elegantly engraved in Viq. d'Azyr's works. The plates of the lymphatics in Hewson's little tract, and of the lacteals in Mr. Sheldon's work, are particularly correct, and many plates of the latter exquisitely finished. The gravid uterus has been illustrated with some admirable plates from Dr. Hunter and Dr. Denman; and the parts concerned in the disease of hernia illustrated in some very distinct masterly engravings by Mr. A. Cooper. Mr. Cheselden's Anatomy of the Bones is the most correct work in osteology, and Albinus' in myology. Eustachius' Tables contain chiefly these subjects, but some of the internal parts are added, and sufficiently explained by Albinus; for the copper-plates of Eustachius were discovered without his own explanations. The gradual development of the parts of the human body, from the period when they can be first discovered, is delineated with equal delicacy and elegance by Hunter and Soemering.

**ANATOMY, COMPARATIVE.** This subject has of late only obtained its share of attention; and the little application that it admits of in the practice of medicine, prevents us from enlarging on it. Where the parts of animals illustrate the functions of the human economy, we shall describe them in their places. Those who wish to pursue the subject will not yet find very ample assistance. The *first* Dr. Monro (for he confessedly merits this epithet in every view) left a little tract on *comparative anatomy*, which, in the limited circle to which he confined himself, is very satisfactory. In the beginning of the last century Blasius published his *Anatome Animalium*; Mr. Collins' two folio volumes on this subject, with numerous plates by Faithorn: the descriptive part is, however, vague and imperfect; the plates are clear and distinct. At this time M. Cuvier is preparing a large, and what will be a most valuable, work on *comparative anatomy*, with numerous very elegant plates. He has permitted one of his pupils to publish his Lectures, of which two octavo volumes only have appeared, and these have been translated into English. Two other volumes were announced as in the press long since; but they have not yet been published. Dr. Harwood, of Cambridge, published some years since a small part of a magnificent work on *comparative anatomy*. It comprehends chiefly the organs of the throat, including, if we recollect rightly, the larynx; and Kircher, in his *Musurgia*, has delineated this organ in all the variety of birds. The detached papers on the same subject, in the Philosophical Transactions, and the Memoirs of the French Academy, we cannot enumerate. A part of the latter may be found in Buffon's Natural History; and many facts of importance in a French continuation of Geoffroy's work on the *Materia Medica*, by Nobleville, containing the animal kingdom. In the anatomy of insects no modern author can rival Reaumur in attention and ingenuity, or Swammerdam in the patient industry and minute dexterity displayed

in the *Biblia Naturæ*. We must add, that the anatomy of fish has not been so carefully and accurately described as by the elder of the present Monros. The anatomy of the cow has been described by Vitet, and that of the horse in numerous modern veterinary publications.

**ANATOMY, MORBID.** Dissections are of the utmost consequence, in connecting the morbid changes with the symptoms that have preceded. Unfortunately, we can more often trace the effects of disease than its cause; and to add to the difficulty of drawing from dissections any useful consequences, in a very few instances only have we received an accurate account of the previous symptoms. Morgagni's work, *De Sedibus et Causis Morborum*, is a most ample and valuable collection of dissections; but, unfortunately, the symptoms of the disease are often imperfectly detailed; and the cases taken from the communications of his friend, Valsalva, are much less satisfactory than his own: this work has been translated by Dr. Alexander; and we have received a valuable abstract of the first part from Dr. Hamilton of Edinburgh. Bonetus, an indefatigable collector, preceded him in this path; and his *Sepulcretum Anatomicum*, amidst many vague and useless narratives, contains facts of value and importance. A selection from this almost forgotten author would still be valuable. The collection of Lieutaud, viz. *Historia Anatomico Medica*, would be more useful, had the previous symptoms been more carefully detailed. At present, many of the facts are numerous and important. The first volumes of the collection of Ruysch's works, contain many singular effects of disease, with excellent plates; and Haller's little volume of Pathology is curious in the same view. Dr. Baillie's late fasciculi of *morbid anatomy* are very important and valuable, as they are illustrated with plates, executed with equal accuracy and elegance: and the medical collection, in our own language, contain many well detailed cases, with the dissections. These volumes are now become so numerous, that a descriptive index to the whole number would be valuable.

*Anatomy* is sometimes used in the sense of analysis, as we find in *anatomia spagyrica*: sometimes figuratively for an exact search and examination.

**ANA'TON.** See **ANATRON**.

**ANATRE'SIS**, (from *ανα*, and *τιτραω*, to perforate). Galen uses this word to express trepanning.

**ANA'TRIPSIS**, (from *ανα*, and *τριβω*, I wear). Friction: sometimes called *tripsis*.

**ANA'TRIS.** See **ARGENTUM VIVUM**.

**ANA'TRON, NATRON**, (Arab). A lake of Egypt, where it was produced. The MINERAL FIXED ALKALI. See **ALKALI**.

On the Peak of Teneriffe the inhabitants call it **SALITRON**, which is their name for salt petre also.

*Anatron* is a name of the spume or gall of glass, which bubbles on the surface while in the furnace; of the *terra Saracenica*, of which are three kinds, the red, black, and azure; and of a white stony excrescence, found on rocks somewhat in the form of moss.

**ANA'TROPE**, (from *ανατρεπω*, to subvert). A subversion or relaxation of the stomach, with loss of appetite and nausea. Vogel defines it, a want of appetite with nausea.

ANA'TUM. See OVORUM TESTA.

ANAU'DIA. } See CATALEPSIS.

ANAU'DOS. } (From *a*, neg. and *αὐδή*, *speech*). Galen confines it to one who hath lost the use of speech, but retains his voice: aphonia signifies the loss of voice.

ANAVINGA. The genus to which this plant belongs was established by Willdenow, under the name *cascaria*, Wild. v. ii. Sp. Pl. 629. It is the *a. ovata* of Reed, and La Marck; employed as a sudorific.

ANA'XYRIS, (from *αναξυρίς*, *the sole of a shoe*,) as the herb so called has its leaf shaped in that form. See LAPATHUM VULGARE.

A'NBAR. See AMBRA.

A'NCEPS, (from *am*, *on both sides*, and *caput*, *the head*). It implies hesitation respecting the nature of a disease, or the effects of a medicine.

A'NCHA, ANKA. An Arabic word, to press upon; as the thigh, which is the support of the body. See FEMUR.

A'NCHE, OS. See FEMORIS, OS.

A'NCHILOPS, or A'NCHYLOPS, (from *αγχί*, *near*, and *ὤψ*, *the eye*). See ÆGYLOPS.

ANCHO'AS. The Mexican name for the male ginger.

ANCHORA'LIS, PROCE'SSUS, (from *αγκυρα*, *an anchor*). See PROCESSUS CORACOIDES.

ANCHU'SA, ALCANNA. ALKANET ROOT. *Anchusa officinalis* Lin. Sp. Pl. 191; a mucilaginous plant of weak powers.

ANCHU'SA TINCTORIA, Lin. Sp. Pl. 192. The roots are of a deep purplish colour outwardly; and they give out a deep red colour to oil, wax, unctuous substances, spirit of wine, and spirit of turpentine.  $\frac{1}{10}$ th part of the bark of this root colours  $\frac{3}{10}$ ths of any of the above matters; by a gentle heat they most perfectly extract its colour. It is now only used for colouring oils, ointments, and plasters; formerly it was considered to possess astringent powers, and recommended in many disorders.

A'NCHYLE. See ANCHYLOSIS. A contraction of a joint; or the back part of the knee.

ANCHYLOMERI'SMA. In Sagar's Nosology it signifies a concretion or growing together of the soft parts.

ANCHYLO'SIS, (from *αγκυλος*, *crooked*). A STIFF JOINT, a species of which is called *orthocolon*. It is a species of *contractura* in Cullen's Nosology. When the bones are immoveable, and the joint in a bent position, it is called *ancyle*: but if the limb be straight, and cannot be bent, *orthocolon*. Petit divides this case into the true and false; in the true the bones are united; in the false, from the contraction of the tendons, the limb is rendered immovable, without the joint being injured.

The bones are covered at their ends, where they form joints, with cartilages, to facilitate their motion, and to prevent any further production of bone; and if these cartilages should be eroded, a bony excrescence will follow, and produce this disorder: it is sometimes, however, the cure of worse misfortunes.

The general causes are, a caries, abscesses in the joints, ossification of the ligaments, scrofula, and rickets, contraction of the tendons.

When the bones are united, the cure is impossible; and, whatever else may be the cause, very uncertain, on account of the difficulty of reaching the seat of the disease; often from the difficulty of knowing the part of the joint principally affected.

The most simple case of this kind is that from a long confinement of the limb to one position; an inflammatory affection of the ligaments, from external injuries, is generally difficult; rheumatic and arthritic matter falling on the joint hardly ever to be removed; but the worst case is that from a white swelling, a scrofulous disease.

If the cause is a rigidity of the tendons, emollient topics are the proper means of relief. Dr. Lobb, from observing the gloves soften hard leather with a mixture of the white of egg and water, proposed it in some instances of this kind, it is said, with the best success.

Others commend mucilaginous oils, of which the neat's foot oil is the best.

If an inflammatory state of the ligaments is the cause, astringent and stimulant applications, and not emollients, are the best. Blisters, the most powerful remedy of this sort, have in many instances succeeded in this case while it was in a recent state; but many blisters must be often applied in succession.

In more inveterate cases a few cures have been effected by the pump. Warm or cold water, falling from a considerable height upon the part, hath, by repetition, been successful. The warm bath hath had the like happy effects by continuing in it an hour or more, and repeating the application for several weeks successively. After the bath or the pumping, emollients may be applied.

When the joints themselves are not diseased, pumping and friction are perhaps the best remedies, gradually exercising the joint by a motion, which extends the muscles without giving great pain. When some mobility is obtained, the extension of the muscles may be preserved by any instrument, which keeps them in the state procured by the action of the remedies. Mr. Bell has recommended an useful machine for preserving this extension in the knee joint; and MM. Koeler and Trampel have described others, in no respect of superior efficacy.

Of the applications, some have preferred the more stimulating and astringent, as the fat of ducks, the brine of herrings with vinegar, vitriol, or alum; arum root often joined with the cicuta; the sabine ointment applied to blistered parts; oil of marjoram, turpentine, &c. Others recommend the more relaxing oils, the althæa ointment, with warm applications of water and vapour. The gum ammoniac with vinegar of squills is supposed to have a good effect, on a principle not easily explained. In general, where there is a deficiency of the synovia of the joint, the stimulating applications are the best; where the fault is in the rigidity of the tendons, the relaxing ones.

In scrofulous cases, all means hitherto used have failed; however, as palliatives, when the tumour bursts into ulcers, the aqua lithargyri composita, and similar preparations, are considerably beneficial.

See Petit on the Diseases of the Bones. Heister's Surgery. Mém. de l'Acad. Royale des Sciences, years 1721 and 1728. Aikin's Obs. on the Preparations of

Lead. Bell's Surgery, vi. 283. White's Surgery, 431. Boyer on the Bones.

ANCHYNO'PES. See LOLIUM.

ANCHYROI'DES, (from *αγκυρα*, an anchor, and *ειδος*, forma). A process of the scapula, not unlike the beak of an anchor. See CORACOIDES.

A'NCI, also GALIANCON (from *γαλη*, a weasel, and *αγκων*, an elbow) ANCUS, WEASEL-ELBOWED. When the head of the humerus is in the arm-pit, such patients are also called *mustelanei*. The disorder which this name expresses, is a luxation of the humerus in the uterus; or in infancy, when an abscess thrusts out the head of the bone. Those who have the foot similarly distorted are called *vari* and *volgi*.

A'NCINAR. See BORAX.

A'NCON, (from *αγκαζομαι*, to embrace,) because the bones meeting, and being there united, fold one into another. See OLECRANON.

ANCONÆ'US, (from *αγκων*, the elbow,) MUSCULUS: called also *cubitalis musculus*. It rises by a round short tendon from the outer condyle of the os humeri backwards; it soon grows fleshy, and is inserted into the ulna about three inches below its head, serving to extend the fore-arm. This muscle is reckoned by some as a part of the *brachius externus*; from which in dissection it cannot be separated without violence.

A'NCORA. See CALX.

ANCORA'LIS. See CORACOIDES PROCESSUS.

ANCO'SA. See LACCA.

A'NCTER, ANCTERIA'SMOS, (from *αγκω*, to blind). The Greek term for the fibula, or button, by which the lips of wounds are held together, which operation Galen calls *αγκληριασμος*, *ancteriasmus*. *Infibulatio*, an operation which consisted in passing a fibula through the prepuce of stage players and buffoons.

ANCU'BITUS. That affection of the eyes in which they seem to contain sand. It is also called *petrificatio*.

ANCUNULENTÆ. Filthy women are so called during the time of menstruation. *Ancunulenta* is composed of *am*, from *αμφι*, about, and *κονιαω*, to pollute. From the Greek *κονις* comes the Latin *cænum*, mud or filth, whence are derived *cunire* and *inguinare*, to defile.

ANCYLOBLE'PHARON, (from *αγκυλος*, bent, and *βλεφαρον*, an eye-lid). A disease of the eye which closes the eye-lids.

Sometimes the eye-lids grow together, and also to the tunica albuginea of the eye, from carelessness when there is an ulcer in these parts. Both these cases were called *ancyblepharon* by the Greeks.

This disorder derives its origin from glutinous discharges, such as attend most ophthalmies; chiefly in ulcerated eye-lids, and is prevented by warm milk, and absorbent or abstrigent powders. If the coalition is a perfect concretion of the palpebræ with each other, or with the eye, there is sometimes a small aperture, which is generally in the great angle of the eye; if there should not be any, a perforation must be made in either angle, a probe with a groove then introduced, and with a fine edged knife let the parts be separated. If the eye-lids adhere to the globe, they must be carefully divided from each other; being more sparing of the eye-lid in the operation than sclerotica. If the adhesion is only to the conjunctiva, blindness is not the consequence; if on the cornea, the sight is generally

lost. This may be supposed to happen when the disease has arisen from a cause that affects the whole eye, as a violent burn, hot lime, or any other acrid fluid in the eye. In this case the cornea adheres to the eye-lid, and the ball of the eye feels collapsed; a strong light cannot be perceived through the lid, and the motion of the ball of the eye cannot be distinguished. This kind of adhesion is sometimes called *symblepharon*, and it is often firm and fleshy. If the adhesion is not to the cornea, it may be separated by the knife; but the greatest caution is necessary not to injure the sight. No directions can assist the operator, who must be left to his own judgment and dexterity. If the adhesions are chiefly membranous, a blunt knife *only* will easily separate them, with little danger. Hildanus attempted the separation by passing a silk, with the assistance of a probe, into the eye at the external canthus, and out of it at the internal; the ends were joined, and a small bit of lead suspended, whose weight gradually, and with little inconvenience, separated the agglutinated parts. This method however is chiefly useful in the slighter cases, and would have little effect when the adhesions were general to the ball of the eye. The re-union is better prevented by injection, or lint placed between the eye-lid and ball of the eye, after dipping it in some mild liniment, than by a plate of lead, as recommended by Sauvages; as that might, from its hardness, bring on inflammation.

When the eye-lids adhere slightly, and the complaint has not been of long duration, they may be separated, according to Mr. Bell, by the end of a blunt probe insinuated behind them, so as to tear them asunder; but when they adhere firmly, or to the eye-ball, he advises slow dissection of every adhering fibre, and then the eye only to be covered with a piece of soft lint spread over with Goulard's cerate, or any other cooling emollient ointment; and after the first dressing, a small portion of the same to be daily insinuated between the eye-lids. Perhaps, in preference to all others, one part of mercurial ointment, with four parts of axunge, may be introduced twice a day: the parts may be bathed twice a day, also, with a weak solution of the zincum vitriolatum purificatum, or cerussa acetata. When the whole eye-lid is closed, a slight opening may be made at either canthus to introduce the probe and divide the eye-lid through its whole course, and the divided edges should be dressed with Goulard's cerate, or any other cooling application. The eyes should not be kept long shut; and, even after the first nap, they should be opened and the dressing renewed. See Wallis's Nosologia Methodica Oculorum, p. 51. Bell's Surgery, vol. iii. p. 297. Cullen's First Lines, vol. i. p. 271. edit. 4.

ANCYLOGLO'SSUM, (from *αγκυλος*, crooked, and *γλωσσα*, the tongue). A contraction of the ligaments of the tongue: TONGUE-TIED. Vogel defines it to be an adhesion of the tongue to the adjacent parts, so as to hinder sucking, swallowing, and speaking.

Some have this imperfection from their birth, others from some disease. In the first case, the membrane which supports the tongue is too short or too hard; in the latter, an ulcer under the tongue, healing and forming a cicatrix, will occasion it; these speak with some difficulty, and are called by the Greeks *μόγυλαλοι*. See MOGILATIA.

The *ancyloglossi* by nature are late before they speak, but when they begin they soon speak properly; these we call tongue-tied, and the membrane which confines the tongue may be cut with scissors, being careful not to extend the points of the scissors so far as the frænulum. When the child's tongue is tied, he does not suck freely, he loses the nipple very frequently, and whilst sucking he makes a chucking kind of a noise. The instances rarely occur which require any kind of assistance; for if the child can thrust the tip of its tongue to the outer edge of its lip, this disease does not exist; and if the tongue is not greatly restrained, the frænulum will stretch by the child's sucking and crying. Besides, without an absolute necessity, which scarcely ever exists, an operation should not be admitted; for without great circumspection, by cutting the frænulum, the nerves passing there may be also cut, and a loss of speech be the consequence.

Sometimes the tongue is bound down with a fleshy substance, which should never be cut through, because a dangerous hæmorrhage might follow, without any attending advantage. It is advisable only to direct the nurse, now and then, to stretch it gently by a light pressure on it with her finger. When, in consequence of delivering a child by the feet, a swelling is observed under the tongue, nothing is required, for the tumour will soon subside.

See Hildanus in Cent. iii. Obs. 28, where he gives an accurate account of the nature, cure, and bad effects that may follow on improper methods being used for the cure of this disorder. He never cuts more of the frænulum than appears ligamentous, and then orders it to be gently rubbed two or three times a day with honey of roses. Bell's Surgery, vol. iv. p. 336. If the tongue is too loose, by the frænulum being too long, or not carried sufficiently near the apex, no remedy can be employed. The only inconvenience arises from the child, in attempting to suck on waking, inverting the tongue, the point of which suffocates him. This must be cautiously guarded against, or the tongue bandage of Petit may be employed.

ANCHYLOME'LE, (from *αγκυλος*, *crooked*, and *μηλη*, *a probe*). A crooked probe, or a probe with a hook.

ANCYLO'TOMUS, (from *αγκυλη*, *a hook*, and *τεμνω*, *to cut*). Any crooked knife used in surgery.

ANCYROIDES, a process of the scapula, so called from *αγκυρα*, *uncus*, *a beak or hook*, and *ειδος*, *form*. See CORACOIDES PROCESSUS.

A'NDA, probably the same with ANDIRA, q. v.

ANDE'NA. Steel which melts in the fire, and may be cast into any form.

ANDHU'RA. See ANDIRA ACU.

ANDI'RA, called also *angelyn et arbor nucifera*. It does not occur in the system of Linnæus.

It is a tree which grows in Brasil, whose wood is proper for building. The fruit is a yellow kernel; it is bitter, astringent, and, if taken inwardly, it destroys worms; ʒ i. of it in powder is a dose.

ANDRA'CHNE, (from *ανηρ*, *a man*, and *αχνη*, *froth*), so called because it was supposed to increase the seminal fluids. See PORTULACA.

ANDRANOTOMIA, (from *ανηρ*, *a man*, and *τεμνω*, *to cut*). The dissection of a male subject.

A'NDRAPHAX, or ANDRAPHA'XIS, (from *αδρας*,

*quickly*, and *αυξω*, *to increase*), so called from its quick growth. See ATRIPLEX FÆTIDA.

A'NDRIA, (from *ανηρ*, *a man*). See HERMAPHRODITUS.

A'NDRIUS, MANLY, (from *ανηρ*, *a man*,—*strong*). It is metaphorically applied to strong wine, or wine from the island of Andros.

ANDROGENI'A, (from *ανηρ*, *a man*, and *γενναω*, *to generate*). A succession of males.

ANDRO'GYNE, } (from *ανηρ*, *a man*, and *γυνη*, *a*

ANDRO'GYNI, } *woman*). EFFEMINATE MEN, and HERMAPHRODITES. See GYNANTHROPUS.

ANDRO'MACHI THERI'ACA. This medicine of *Andromachus* hath above sixty ingredients in it. It is needless to repeat the universal good ascribed to this composition by its author; or its high reputation in consequence of its being considered as an antidote to all poisons. See ALEXIPHARMICA.

So many drugs were crowded into one medicine, that a concurrence of similar ingredients might be more effectual; but, according to Pliny, it was only to make people more confident in their favour. An idea indeed seems to have prevailed in the middle ages, that numerous ingredients rendered a formula better adapted to a variety of diseases. From the number of poisonous plants sometimes used in such remedies, it seems to have been also an object to accustom the constitution to their effects, so that, at other times, they may be harmless.

The treacle of *Andromachus* is called VENICE TREACLE, because great quantities of it were made there, and conveyed to other countries. It is now disused.

ANDRO'NION; i. e. ANDRONIS PASTILLI, the troches of Andron. They are made with alum, balaustines, &c.

ANDROPHAGE, (from *ανηρ*, *a man*, and *φαγειν*, *to eat*). Man-eaters, cannibals. A few nations of this savage disposition still exist; and the inhabitants of New Zealand, our antipodes, are certainly such.

ANDROPO'GON NA'RDUS. See NARDUS ITALICA.

ANDROPO'GON SCHÆNA'NTHUS. See JUNCUS ODORATUS.

ANDROSA'CE, *tubulana acetabulum*, and also called *umbilicus marin. cochlea celata, acetabulum marinum minus, fungus petræus marinus, cotyledon marina*, and SEA NAVEL-WORT. It is a sub-marine production, found on the rocks and shells of fishes about the coasts of the Mediterranean. It consists of numerous, slender, short filaments, more or less bent or arched, of a whitish or gray colour, hard and brittle, bearing each upon the top a striated concave body, nearly of the figure of an inverted cone.

In powder it is given as a vermifuge and diuretic. It does not differ from coralline. In the flame of a candle, when dry, it yields a dazzling brightness, and the coralline does the same.

ANDROSACES, SUMMER NAVEL-WORT.

A plant on the sea coasts of Syria. It is called *androsace*, (from *ανηρ*, *man*, and *ακος*, *a cure*.)

Two drams of this herb, or of its seed, taken in wine, powerfully promote urine. The species is uncertain.

ANDROSÆ'MUM, or ANDROSÆ'MOM. *Hypericium, androsæmum*, Lin. Sp. Pl. 1102. Also called *Siciliana, clymenum Italarum, ascyrus, ascyos, hyperi-*

*cum, ciciliana, dionysias*. In English it is named TUT-SAN, or ALL-HEAL, PARK-LEAVES, and ST. PETER'S WORT. It grows in hedges and thickets. Two drams are moderately purgative, but it is rarely used.

The name *androsæmum* is from *ανηρ*, a man, and *αιμα*, blood, for it makes the fingers red if they rub it. *Tut-san* is a corruption of the French words, *tout-sain*, which signifies all-heal.

ANDRO'TOME. See ANDRANATOMIA.

ANDRUM, an endemic disease on the coast of Malabar. It is called in the language of the country the popular water rupture, and is in reality HYDROCELE, q. v. The disease is supposed to arise from the brackish water, and is preceded by an erysipelas of the scrotum. It is prevented by putting at the bottom of the wells some pure sand, through which the water filters, and is rendered more pure. The partial remedy of tapping is the only one employed, and this is frequently repeated.

ANDSJUDÆN. See ASAFÆTIDA.

ANE'BION, (from *αναβαινω*, to ascend,) so called from its quick growth. See ANCHUSA.

ANECPY'ETUS, (from *α*, neg. and *εκπυετος*, suppurated,) not admitting of suppuration.

ANEILE'MA, or ANEILE'SIS, (from *ανειλω*, to roll up, or involve). An involution of the bowels from flatulence or gripes.

ANE'MIA, (from *ανεμος*, wind). The name of a disorder which Hippocrates mentions, but does not describe; probably flatulence.

ANEMO'NE, (from *ανεμος*, wind,) so called because it will not open its flowers till blown upon by the wind. WIND FLOWER, or CORN ROSE. Called also *phenion*. *A. hepatica* Lin. Sp. Pl. 758. The root of the scarlet *anemonies* is detersive if bruised while fresh, and applied to ulcers, and on the skin it raises blisters. The herb hath been used in collyriums and errhines. See HEPATICA NOBILIS.

ANEMO'NE PULSATILLA. See PULSATILLA NIGRICANS.

ANEMONO'IDES, (from *ανεμωνη*, the wind flower, and *ειδος*, forma,) also called *memorosa*, *ranunculus*, *phragmitis albus vernus*. The WOOD ANEMONE; resembling in virtues the garden anemone.

ANENCE'PHALOS, (from *α*, neg. and *εγκεφαλος*, the brain). Born without brains; metaphorically foolish.

A'NEOS, (from *α*, non, and *ανω*, clamo, to bawl out). Loss of voice and reason.

ANEPITHY'MIA, (from *α*, non, and *επιθυμια*, desire). Loss of APPETITE. See ANOREXIA.

A'NE'RIC. }  
A'NE'RIT. } See SULPHUR VIVUM.

A'NE'SUM. See ANISUM.

ANETHO'XYLA, the woody root of dill.

ANE'THUM, } (from *ανω*, after, and *θω*, to run,) so  
A'NET, } called because its roots run out a great way. DILL, or ANET. It is the *anethum graveolens* Lin. Sp. Pl.

The herb, flower, and seeds, are medicinal, but the seeds only are used in the shops. They are carminative and antispasmodic: ʒi. to a dose is reckoned specific in hiccoughs. In some symptoms of indigestion, arising from a relaxation of the stomach, they are said to be serviceable, and more efficacious than the other seeds, by promoting a secretion of milk. They give

over all their virtue by distillation to water, but not by digestion or infusion. With the distilled water there arises a considerable portion of oil, which, as a carminative against hiccough, from two to four drops are given for a dose. Rectified spirit of wine obtains all the virtue by digestion, but takes very little over with it by distillation. The medicine, and its simple water, are alike deservedly neglected.

ANE'THUM FÆNI'CULUM, FRU'CTIBUS OVA'LIS. See FÆNICULUM VULGARE.

ANE'TICA, (from *ανημι*, to remit). See ANO'DYNA.

ANEURI'SMA, (from *ανευρυνω*, to dilate much,) called also *hamatocele arteriosum*, *abscessus spirituosus*, *emborysma*. See ABSCESS.

The *aneurism* is a tumour arising from the dilatation or rupture of the coats of an artery. Arteries only are the seat of this disorder; and any artery, in any part of the body, may be thus affected, as any vein may be the seat of a varix. It is defined a soft pulsating tumour upon an artery.

Dr. Hunter divides *aneurisms* into four kinds; viz. the true, the false, the mixed, and the varicose.

#### First, OF THE TRUE ANEURISM.

The true *aneurism* is formed by a dilatation of the artery. It may happen in any part of the body, but most frequently is found in the curvature of the aorta, which is subject to this disorder from the extraordinary impulse of the blood; from the curvature it runs upwards along the carotids, or the subclavians, generally increasing, till by its great distention it is ruptured, and the patient dies.

The degrees of the dilatation of the aorta, in cases of this kind, are various; in some the curvature of this artery hath been so enlarged as nearly to fill the upper part of the breast. It is singular, that the part of the vessel which is the weakest, and where the disease begins, is apt to be stretched more in proportion than other arteries; and to form particular cells, where they meet with firm resistance, more than where their support is soft and yielding.

The sac formed by the distention of the artery is not a distention of a particular coat, but of the whole substance of the vessel; but the thickness of the coats of these sacs continues only to a certain period; for when the vessels of the coats can no longer yield, the circulation grows languid, the sac becomes thinner at its apex, and soon after bursts. As the *aneurismal* tumour also increases in size, it meets with resistance from the neighbouring parts; and as the coats will be more or less affected, according to the degree of the resistance, in some places they will be simply distended, in others absolutely destroyed. Where the *aneurism* presses against the diaphragm, it will be thinner than where it suffers no pressure; it is still thinner where it presses against the tendinous part of this muscle; and where it presses the spine, it is the soonest destroyed. A proof that all pressure must be avoided in such cases.

The blood that fills these tumours is always fluid, by being constantly renewed; but, notwithstanding this blood is fluid, its passage in the tumour is retarded; and this remissness in its motion, which is more or less considerable according to the size of the *aneurism*, occasions some of the fibrin of the blood to separate from

the red part; and adhering to the internal coat of the *aneurism*, it there forms fibrous strata, which may easily be taken for real membranes by those not accustomed to observe them. These fibrous strata cannot be dispersed by any means, either external or internal; and pressure cannot be used, because it will destroy the coats of the artery.

Secondly, THE FALSE ANEURISM, called *Ecchymoma Arteriosum*,

Is formed by a rupture or wound in the coat of the artery, and is of two kinds, viz. the diffused and the circumscribed.

The DIFFUSED is that in which the extravasated blood runs through the cellular membrane, in the interstices of firmer parts: this generally makes a rapid progress, may extend itself to a great distance, and hath little or no pulsation except very near the aperture of the artery; but these circumstances will somewhat vary, according to the size of the opened artery and the strength of the circulation. This species of false *aneurism* is analogous to the emphysema, and is the highest species of ecchymosis.

The CIRCUMSCRIBED TUMOUR beats, and sinks under pressure, like the true *aneurism*; and indeed cannot be distinguished from it except by the knowledge of its cause, or by a careful dissection of the part: it appears soon after the accident which gave rise to it, and is commonly slow and gradual in its progress. It happens when the orifice in the artery is very small, so that the blood flows but slowly, and finds the adjacent membranes so firmly united as to keep it within a certain channel. It consists of one bag with a smooth inside, and communicates by an aperture with the cavity of the artery. This species of *aneurism* is, perhaps, the most common among those that happen in the arm after bleeding, especially when a considerable pressure hath been made immediately after the accident.

Thirdly, THE MIXED ANEURISM,

Is formed partly by a wound or rupture in the artery, and partly by a dilatation. It cannot easily be distinguished from the circumscribed species of the false *aneurism*; and will often so emulate the true one, as not to be distinguished from it but by a careful dissection.

Fourthly, THE VARICOSE ANEURISM, OR THE ANEURISMAL VARIX,

Occurs when there is an anastomosis, or an immediate communication between the artery and the vein of the part where the patient hath been bled, in consequence of the artery being wounded through the vein, so that blood passes immediately from the trunk of the artery into that of the vein, and so back to the heart.

This species differs from the common spurious *aneurism* in one circumstance only, viz. the wound remaining open in the side of the vein as well as in the side of the artery. But this circumstance will occasion a great difference in the symptoms, the tendency of the complaint, and in the proper method of treating it.

Mr. Bell, in his System of Surgery, divides the *aneurism* into two species, viz. the encysted, and the diffused. The *encysted* includes all those instances in which, the coats of the artery being only dilated, the

blood is confined in its proper coat: of this kind he reckons the *varicose aneurism*. The *diffused* includes all those in which, from an aperture in the artery, the blood is spread in the cellular membrane out of its proper course.

The causes of *aneurisms* are various. A natural weakness in a part of an artery is the immediate cause of the true *aneurism*. The internal causes are, a fulness of the arteries concurring with some violent motion or concussion; an internal tumour pressing on some part of an artery; or violent action, sudden anger, vomiting, &c. which propel the blood too forcibly to some particular part. By stretching the artery, a true, or by bursting it, a false *aneurism*, or the mixed one, will be thus formed: convulsions, and other violent spasmodic symptoms, with other concurring causes, may be ranked in the number of internal causes. In some instances the coats of the artery are unusually and irregularly weak. We then find *aneurisms* through the whole arterial system; and the predisposition to this complaint is styled *diathesis aneurismatica*. Externally, strains, blows, and punctures, are the most frequent causes; pressure used on a true *aneurism*, by bursting the coats of the artery, produces a false one; suspending the breath, as in lifting great burthens, wrestling, &c. may occasion either.

It hath been said that a polypus, existing internally, sometimes occasions an *aneurism*; but Dr. Hunter observes, that it rarely or never happens that a polypus is formed till the last moments of life, when the heart's power having nearly ceased, the whole blood cannot be propelled from the heart; which, when found after death, has been supposed to have pre-existed, and to have been the cause of what it was only the effect.

There is no certain criterion by which to ascertain the existence of internal *aneurisms* before they approach to the surface of the body; whatever symptoms they occasion before they form a tumour externally, as they may be produced by other causes, are but equivocal signs. The *pathognomonic sign* of all the species of *aneurism* is, a perceptible pulsation in some part of the tumour, more or less manifest, as the artery is seated superficially or deep; yet we shall find, that any other tumour receiving pulsation from an adjoining artery will sometimes resemble it; and when the effused blood is in large quantity, it will obscure the pulsation. The true *aneurism* is generally of an oblong figure, and hath a strong pulsation in it; it subsides on depression: if it is an *aneurism* of the aorta, a strong pulsation is perceived against the sternum and ribs on every systole of the heart; and when it extends above the sternum, there is a tumour, with pulsation. These tumours are without pain or discoloration in the skin, except on the point of bursting; they subside by pressure while the blood is fluid, but when it is coagulated they yield in a very slight degree; if the sac has a narrow basis, the blood re-enters the artery with a hissing noise when the tumour is pressed. Sometimes there is a redness from the expansion of the parts beyond their capacity, or a dark colour from the putrefaction of the blood, in which case a fever and fainting also occur. The common appearances of an *aneurism* from the wound of a lancet are a discharge of blood through the orifice of the skin, by jerks, instead of an uniform stream; and on stopping the orifice, the blood spreads between the

muscles of the shoulder and arm, constituting the diffused *aneurism*: in this case the arm becomes livid from the ecchymosis, and the blood coagulating, obscures any sensible pulsation.

In the false kinds of *aneurism*, the cyst is probably formed of a portion of the aponeurosis that runs over the vessel, which, from extravasated blood underneath, is thickened and expanded: that this membrane is the cyst, seems to be confirmed by our so readily discovering the puncture in the artery upon opening the tumour; or it may be formed of the cellular membrane, which admits both of thickening and expansion.

In the varicose *aneurism*, the vein that was punctured will become varicous, and will have a pulsatile jarring motion, on account of the stream from the artery; there will be a hissing noise, which will be found to correspond with the pulse; and the blood in the tumour will be almost entirely fluid, because it is kept in constant motion: it is soon formed to its largest size, and so remains, if not disturbed by imprudent management: no considerable inconveniences arise from it. This sort of *aneurism* may be further known by placing a finger over the orifice in the artery, where the stream of blood propelled into the vein at every pulsation is felt: by applying the ear to the tumefied vein, a tremulous motion and noise are perceived; by pressing the corresponding artery, this motion and noise cease; and on the removal of this pressure, the motions, &c. return; the artery becomes larger in the arm and smaller in the wrist; the vein being emptied by pressure, instantly fills again on taking the pressure off; the pulse at the wrist grows weaker as the artery above enlarges.

The beginning *aneurism* in the aorta should be distinguished from a palpitation of the heart; from hysterics, in which symptoms of suffocation sometimes attend; from fever with fainting, both which are sometimes the consequence of false *aneurism*; from varices of the veins and their effects; from an emphysema; from an ecchymosis; from encysted swellings in the neck, in which is often perceived a strong pulsation from the stroke of the adjacent artery; and from tumour formed in consequence of ruptured veins.

The *aneurism* of the aorta may prove fatal by injuring the general health, as it continues to increase in its size; it may be supported during many years, but no cure can be attempted, nor other palliatives used than what consist in composure of mind and quietude of the body. All *aneurisms* are incurable that lie too low for the operation; and, if unadvisedly opened, the patient's life is in immediate danger; for bandages, which are the only palliatives in such cases, are but uncertain aids. The diffused *aneurism* is not only subject to hæmorrhages, but also to mortification.

The method of cure is the same in the true, the false, and the mixed *aneurisms*: the varicous needs but little, if any assistance: if it is enlarged by exercise and becomes painful, indulge a little rest, and moderate the future labour; perhaps bathing the part with a little spirit may afford some relief, but bandages and all other pressure must be avoided.

To palliate, when the operation is impracticable, bleed as often as is required to keep the force of the circulation moderate; let the diet be temperate, and the exercise very gentle; keep the bowels constantly free; where pressure is used, it must be such as only

lessens the force of the blood, but does not resist it; flannel bandages, or knit stockings, &c. are the most proper for this purpose. But all pressure should be avoided when the aorta is the seat of the *aneurism*, however the tumour may appear externally: it is true that, if the integuments give way, and the coagulum formed on the inside of the tumour hath lost its support, the assistance of a bandage is immediately necessary, as it is the only means to prevent a fatal hæmorrhage; in this dilemma, if the substitutes to the integuments are judiciously applied, and accompanied with such topical medicines as resist both suppuration and putrefaction, the life of the patient may be preserved for some time. In one instance, recorded in some of the Medical Observations, where several *aneurisms* occurred in the lower extremities, the blood lost by the bursting of one cured the rest. This circumstance might lead us to try active bleeding in true *aneurisms*.

When the operation can be admitted, it is advisable first to attempt the cure by compression, because it sometimes proves effectual; is always a good preparatory step to the operation, by its enlarging the collateral anastomosing branches, and disposing the part to have a more free circulation after the division of the artery: but when the tumour is large, the palliative method should not be long continued, because it injures the neighbouring parts, and will occasion more inflammation and sloughing when the operation is performed.

The pressure, whether before or after the operation, should be confined as much as possible to the affected part, that the passage of the blood through the anastomosing vessels may be free; by which we may prevent the mortification that sometimes ensues from a want of a free circulation.

Some few instances of small *aneurisms*, and punctures of the artery from bleeding, have succeeded by the use of a bandage, but they almost all require the operation at last, which is performed nearly in the same manner in every part; but larger *aneurisms* cannot receive any advantage from the pressure; therefore, when used long enough as a preparative to the operation, the latter should not be delayed. Plenck's apparatus is well adapted to close the wound instead of the common bandage; and the German surgeons have introduced several refinements in the management, which are perhaps unnecessary. Yet where the *aneurism* has been cured by compression, it is more probable that the canal of the artery is obliterated, than that the wound is so firmly healed as to resist the arterial current.

If, however, the cure be attempted in this way, the pledget should be very carefully laid on the wounded artery, so as to close the wound accurately without pressing on the veins or any anastomosing artery; the limb should be kept at rest, blood taken from the other arm, and every part of the antiphlogistic plan rigorously adopted. When it is probable that the wound of the artery is firm, the bandage and pledget should be removed; and gently loosening the tourniquet, we should observe whether any tumour appears on the part. If there should not, a more moderate pressure must be still for a time continued.

In the event of having wounded an artery, M. The-den advises us to let the blood flow for a time, and while the proper bandages are preparing, to keep a strong general pressure on the cavity of the elbow. A

spiral bandage must then be applied, inclosing a cylindrical compress along the artery. The whole must be wetted with his own *agua traumatica*, q. v.; but as wetting contracts the linen, the bandage should not at first be drawn too tight. In three or four days the bandages grow slack, and they must be again applied, and every precaution taken against any of the folds slipping.

Mr. Bell observes, that in diffused or false *aneurisms*, pressure cannot be applied to the artery alone, without at the same time affecting the refluxent veins; and as this circumstance, by producing an increased resistance to the arterial pulsations, must undoubtedly force an additional quantity of blood to the orifice in the artery, there is reason to suppose it hath been productive of mischief. But though pressure ought never to be attempted in any period of the diffused *aneurism*, yet in some stages of the other species it may be often employed with advantage. In their early stages, while the blood can be yet pressed entirely out of the sac into the artery, by the use of a bandage of soft and somewhat elastic materials, properly fitted to the part, much may be done in preventing any considerable increase of the swelling: indeed, by this continued support, complete cures have been at last obtained. Yet, though pressure to a certain degree hath sometimes proved useful, it ought never to be carried to a great length: tight bandages, in these cases, always counteract the intention. The greatest length to which pressure ought to go, should be to serve only as an easy support to the parts affected. With compression, other means should at the same time be used; such as low diet, occasional bleeding, a lax state of the bowels, freedom from strong exercise, &c.

#### THE OPERATION FOR THE ANEURISM IN THE HUMERAL ARTERY.

Having taken away some blood, and promoted such other discharges as seem needful, apply the tourniquet near the shoulder, tighten it so that the pulse cannot easily be perceived; lay the arm in a convenient situation; then make an incision on the inside of the biceps muscle, above and below the elbow, a considerable length, which, being in the course of the artery, will discover it as soon as the coagulated blood is removed. Be careful not to cut the larger veins, nor the bag; the same attention is necessary in cutting the aponeurosis of the biceps; for this aponeurosis, the capsula, the bag, and the skin, are all united by the pressure.

If the orifice does not readily appear, let the tourniquet be loosened, and the effusion of blood will direct you to it; then carry a crooked needle armed under it, tie the vessel just above the orifice, and when you have secured the upper part, slacken the tourniquet a little; for if on slackening it there is any hæmorrhage from the inferior parts of the artery, it plainly appears that the collateral branches are open, and that there is a free circulation. The first ligature secured, make a second a little below the orifice, and leave the intermediate space of the artery to slough away without dividing it.

Avoid taking up the nerve with the ligature if you conveniently can; the readiest method to do this is,

as it lies on the inside, at a little distance from the artery, to relax that vessel by bending the arm moderately, and to raise the artery from its bed by a probe introduced into its orifice, or by pinching it up with the finger and the thumb: the nerve is easily distinguished from the artery by feeling; and thus the artery may be drawn from the nerve. If the nerve should be taken up, and a portion of the adjacent flesh being taken up with it, no inconvenience need be feared.

After the operation, the limb is generally some little time without pulsation, which, if it does not recover in twenty-four hours, amputation is not to be deferred. This operation is indeed often necessary; but warm spirituous applications, and dry heat from warm sand and ashes should be first tried, and continued so long as the operation can be safely deferred.

In the London Med. Obs. and Inq. vol. ii. page 360. is an instance of an *aneurism* in the arm being cured by the operation; but, instead of the ligatures, a steel pin was passed through the lips of the orifice in the artery, and secured by twisting thread about it, as in the hare-lip; after a few days the pin came away with the dressings.

Under some particular circumstances, taking up the femoral artery in popliteal *aneurisms* may be performed with success, and the leg preserved, where the misfortune occurs from falls, bruises, or punctures, in sound, healthy constitutions; but if the *aneurism* arises gradually in habits where there is reason to suspect a diseased state of the arteries, amputating the limb is certainly the least dangerous mode, and should be preferred.

The advantages of Mr. Hunter's operation for the popliteal *aneurism*, viz. tying the artery far above the aneurismal sac, are owing to the wound being small; for the true aneurismal sac is untouched, and disappears from absorption; as well as from the greater probability of the artery in a distant part being sound. Mr. Lambert's method of stitching the wound of the artery by the hare-lip suture (Med. Obs. and Inq. vol. ii. p. 360), and M. Descham's (*Médecine Éclairée par les Sciences*, iii. 67), have been seldom followed, or generally approved.

See instances of *aneurisms* of the femoral artery being cured in the Lond. Med. Obs. and Inq. vol. iii. p. 106. And in the Edinb. Medical Commentaries, vol. ii. p. 176. Also in Warner's Cases of Surgery.

ANEURI'SMA PRÆCORDI'UM. Called also *cardiognus*, *cardionchus*; *aneurism* in the heart, or in

the aorta near the heart, which occasions pain in the præcordia.

ANFRACTUO'SUS, (from *an*, and *frango*, to break). ANFRACTUOUS. Full of windings: called *anfractuosities*.

ANG. ET ANGUIL. The abbreviation of Simplicii del excellenti m. luigi Anguillara. Vcnct. 1561, 8vo.

ANGEIOTO'MIA, (from *αγγειον*, a vessel, and *τεμνω*, to cut). An opening of the vessels, as in arteriotomy and phlebotomy. It also signifies a particular dissection of the vessels for anatomical purposes.

ANGEIOTOMI'STA. An ANGEIOTOMIST. A person skilled in the course of the blood vessels, or who can dissect them readily.

ANGELICA ARCHANGE'LICA. So called? ANGELICA SATI'VA. [from its angelic virtues.] Called also *imperatoria sativa*, *pectoraria herba*. It is the *angelica archangelica* Lin. Sp. Pl. 360. It is found by the sides of rivulets, on the mountains of Lapland, and is cultivated in gardens all over Europe; the best is said to be produced in Bohemia and Spain: but Linnaeus thinks that the best is that which grows on the mountains in northern countries. The roots are in the greatest perfection in the second spring; they should be well dried and kept in a dry place, and frequently aired, or they grow mouldy, and are the prey of worms. The whole plant is used; and hath been so much esteemed as to have obtained the name of PRINCEPS ALEXIPHARMICORUM. Some physicians think that the English *angelica* differs from the Spanish only in the latter having been long kept, by which the disagreeable flavour of the fresh root is lost. Though all the parts of this plant possess the same virtues in a great degree, yet the root is the strongest. It resembles zedoary as a medicine, but is milder, and a good carminative. Externally applied, it discusses inflammatory tumours in cold habits. By some authors it has been highly praised as a *carminative*, a *stomachic*, *sudorific*, and *emmenagogue*; and considered as a specific against some poisons and malignant fevers: in present practice it is seldom employed. In Lapland it is employed in coughs, and hoarseness. The stalks are roasted in hot ashes, and the flowers boiled in milk till they form a soft extract.

The seeds come nearest to the roots in medical virtue, but scarcely retain either their vegetative or medicinal power until the following spring. The leaves lose nearly all their virtue in drying. A strong water is obtained from either the leaves or seeds by distillation; but spirit of wine best extracts the oil in which the virtues of the dried roots reside.

The stalks and the roots are candied by the confectioners; and the stalks were formerly blanched and eaten as celery. In Norway the roots are sometimes made into bread.

All the species of *angelica* have similar virtues, chiefly differing in the degree, but the *a. archangelica* is the best. The wild sort, in use, is the *angelica sylvestris* Lin. Sp. 361. See LEVISTICUM.

ANGELICA PRATENSIS APII FOLIO. See OREOSELINUM. Also a name of the *saxifraga anglica*.

ANGELICA GRANA, a name of Dr. Anderson's pills.

ANGELICUS PU'LVIS. See MERCURIUS VITÆ.

ANGELOCA'LOS. The true name of the twenty-

fourth appellation of Myrepsus, and not, as is commonly writ, *alcancali*.

ANGELYN. See ANDIRA.

A'NGI. BUBOES in the GROIN, (from *angor*, anguish). See BUBO.

ANGIGLO'SSI, (from *αγκυλη*, a hook, and *γλωττα*, the tongue). STAMMERERS.

ANG'NA, (from *αγχω*, to strangle,) also called *cynanche*, *kynanche*, *lycanche*. QUINSY; thus named, from an abbreviation of the French word *squinancie*.

It is an inflammation in the parts of the throat subservient to respiration, speech, and deglutition; it is called a STRANGULATION OF THE FAUCES; more properly, an INFLAMMATION OF THE INTERNAL FAUCES. Aretæus supposes that it is named *cynanche*, from dogs being subject to it; or else, because in this species of quinsy it has been said the tongue is inflamed and so swelled, that it hangs out beyond the teeth like a dog's. Cœlius Aurelianus says, that the voice of the patient in the quinsy resembles that of a dog, or a wolf; hence called *lycanche*: or, perhaps, the word *cynanche* is derived from *κυν*, *canis*, and *αγχω*, *strangulo*; because a set of symptoms affect the patient in a species of quinsy, not unlike the appearances observable in hanging dogs.

If the disorder is epidemic, it is so usually between the spring and summer, and after long continuance of cold and rainy weather.

The true *quinsy*, the *cynanche tonsillaris* of Cullen, is an acute inflammatory disorder. The bastard *quinsy* is a milder catarrhal one; and its fever chronic, of the catarrhal kind.

The Greeks give different names to the true *quinsy*, according to the respective parts on which this disorder falls: the Latins, considering the disorder as one, wherever its violence might have more peculiarly been manifest, included them all under the name *angina*; as we under that of *quinsy*. The curious may see the various appellations given to the different circumstances of this disorder in the writings of Aretæus, Cœlius Aurelianus, Hildanus, and Alexander Trallian.

The *cynanche* of Dr. Cullen is placed in the class *pyrexie*, and order *phlegmasie*: and defined a fever, sometimes of the typhoid kind; redness and pain of the fauces; deglutition and breathing difficult, with a sense of straitness in the throat. This genus contains five species:

1. CYNANCHE TONSILLARIS, when the inflammation begins in the tonsils, and affects only the mucous membrane of the fauces with redness and tumour, having an inflammatory fever attending.

2. CYNANCHE MALIGNA, also *ulcerosa gangranosa*, and *ulcerosa* when it affects the tonsils and mucous membrane of the fauces, with tumour, redness, and mucous sloughs of a white or ash colour, spreading and covering ulcers; attended with a typhoid fever, and eruptions.

3. CYNANCHE TRACHEALIS, when it is attended with difficult respiration, shrill inspiration, hoarse voice, harsh sounding cough, scarcely any tumefaction appearing in the fauces, little or no difficulty of swallowing, and the fever inflammatory. This among the Scotch is called the CROUP. See SUFFOCATIO STRIDULA.

4. CYNANCHE PHARYNGÆA ŒSOPHAGEA, when

there appears a redness, particularly at the lower part of the fauces, and swallowing becomes extremely difficult and painful; the respiration sufficiently free, and the fever inflammatory.

5. *CYNANCHE PAROTIDÆA*, when the external parotid and maxillary glands are tumefied, respiration and deglutition slightly affected, and the fever a mild inflammatory one. This species is called the *MUMPS* amongst the English; in Scotland, the *BRANKS*; with the French, *OURLES*. There is also a species of *quinsy* to which children are subject, called *PEDANCHONE*.

The seat of the *cynanche tonsillaris* is properly in the mucous membrane of the upper part of the throat, and all the surrounding parts of the muscles which move the jaws. The young, the sanguine, and those of an inflammatory diathesis, are most disposed to the true *quinsy*; and a disposition to it is often acquired by a few repetitions. The causes are the same as are productive of inflammation in general; particular constitutions and former habits determine the inflammation to particular parts.

If all or most of these parts are inflamed, the case is desperate; for the return of the blood through the compressed jugulars being interrupted, the fauces, lips, tongue, and face swell; the tongue is inflamed, and hangs from the mouth; the eyes are red, prominent, and ghastly; the brain is filled with blood; and delirium, yawning, stertor, strangulation on lying down, with a manifest redness, tumour, pain, and pulsation in the breast and neck, supervene.

The proper symptom of a *quinsy* is, the difficulty of swallowing solids or fluids; for if a large tumour affects the top of the œsophagus, and contracts it, liquids, but not solids, may pass through it; but if the tumour be seated in the top of the larynx, where it is covered with the epiglottis, solid substances, by pressing the tumid epiglottis, find a way to the œsophagus; while liquids, not pressing with equal force, slide through the gaping space, by the tumour, into the *asperia arteria*, and cause great uneasiness.

The complaint is generally obvious to the senses, and can but in few instances be mistaken. Shivering, and other symptoms of inflammatory fever, often precede; but very frequently the difficulty of swallowing is the first inconvenience felt. The florid redness round the fauces, and on every part of the throat, at once points out the disease; and this, with a flow of saliva, often constitutes the whole. When however more violent, the upper part of the larynx, the muscles of the neck, and the œsophagus itself, in a great portion of its track, suffer. The soreness externally is very acute; the breathing difficult, with a wheezing noise; the pain violent, extending to the ear; and deglutition, from the swelling, almost wholly obstructed. The different parts affected are known from the inconvenience attending the performance of their different functions; but we need not distinguish them, as the practice will not differ.

It is not, we have said, difficult to distinguish the inflammatory sore throat, when we reflect that it consists in a difficulty of swallowing, with fever, and a florid redness of the fauces. Scirrhi, spasms, tumours, and venereal swellings, can never be mistaken for this disease; for though there is often an attending redness, yet it is not of the florid kind, nor is inflammatory

fever present. The inflammation sometimes affects the muscles of the larynx, and is in some cases dangerous; yet the easy access that may be obtained to the neighbourhood of the diseased parts, gives us a power of relieving quickly. The greatest danger arises from gangrene, and suffocation from the swelling of the parts, particularly the tonsils. In common sore throat, however, gangrene is a very unusual consequence; and we have more often seen an inflammatory *cynanche* arise from the active stimulants employed in the malignant species, than gangrene from the present disease. When the tonsils suppurate, the previous swelling often threatens suffocation; and it has been thought necessary to open a passage for the access of the air to the lungs through the rings of the trachea; see *BRONCHOTOMY*. We have seen this more than once employed with success, but it has never appeared necessary in our practice. Active gargles to hasten the maturation, bathing the feet often in warm water, or inhaling warm vapours from the mouth of a funnel, sometimes with the addition of camphor, have generally ripened the abscess without danger. If the symptoms are more urgent, the swelled tonsil may be punctured with the point of a scalpel.

The treatment of inflammatory angina is not very difficult. When it is ascertained to be the true *cynanche tonsillaris*—and for the distinction of the greatest importance we must refer to a following article where we treat of the malignant kind—every part of the antiphlogistic regimen should be employed in all its rigour. Diluting liquors, abstinence from animal food, and even animal broths, and cooling purgatives, are highly proper. Gargles should be almost incessantly employed, and a great error prevails in using gargles occasionally only. Two or three times a day will indeed be sufficiently often; but they should never be employed for a less period than from an hour to an hour and a half. The syringe is chiefly useful in children, and in the malignant kind. Bleeding is seldom necessary, except when the swelling of the fauces is rapid and considerable, in healthy strong constitutions: it should then be actively employed, and not less than sixteen or eighteen ounces taken at once, and repeated after eight or ten hours. Such an emergency will, however, seldom occur: it has not at least occurred to us in a practice of above thirty years. Topical bleeding with leeches is sometimes employed, but seldom necessary; and this remedy is inconvenient, as it is difficult to stop the blood, when there is no bone against which a pressure can be made. As a purgative the salts perhaps with senna are preferable.

Vomiting early is often highly beneficial; and even in a more advanced state, if it can be practised without much pain, it is particularly advantageous, from the discharge it procures from the affected glands. We have heard of its being employed to burst an abscess formed on the tonsils; but it is, undoubtedly, at this period, precarious, if not highly dangerous.

Blistering is a remedy of peculiar importance. The plaster has been applied to the back or to the throat. Where the muscles of the trachea are greatly affected, the latter may be proper; and the former is, in no instance, improper. The most useful application of blisters is, however, from behind the ear, extending under the lower jaw to the trachea. The ammonia, either in its mild or pure state, joined with oil, and mustard cata-

plasms have, at times, supplied the place of blisters; and, when the external fauces have been very sore, a common poultice is an useful application. We have not found the addition of camphor either to the liniments or poultices useful.

The kinds of gargle have occasioned some little discussion. In the early stages they have been emollient and discutient; in the latter astringent and antiseptic. A pint of barley water, with two drams of crude sal ammoniac, is a gargle of the former kind. We have not found a cold gargle of water with a portion of brandy recommended; and it has never before occurred to us, but we think it merits a trial. Acids have been reprobated in the early stages: but the disadvantages enumerated are those of the mineral acids. The acetous is, at any period, useful; and the sharper it can be borne, without pain, the more useful. This kind of gargle generally consists of an infusion of baum- or sage, with a portion of honey, sharpened with vinegar to such a degree as the inflamed fauces can bear. The raspberry vinegar however, alone, swallowed slowly, is perhaps equally efficacious with any gargle; and, as it is pleasant, it will be more steadily pursued than a less agreeable medicine. In the same way, a small bit of crude sal ammoniac, or of salt prunella, held in the mouth till it gradually dissolves, has been highly useful. Figs, as they are supposed to have a peculiar efficacy in ripening abscesses, have been often used in decoctions employed for gargles. The addition of squills to the gargle, as recommended by Dr. Fordyce, is seldom of peculiar service.

The mineral acids and astringent gargles are scarcely in any instance required in inflammatory angina, though recommended in the more advanced stages. They are of great service in those inflammations which arise from relaxation; and when angina often recurs, the inflammation is of a less active kind. Decoctions of the oak bark with the vitriolic or muriatic acid, are more effectual than any form of the Peruvian bark. The myrrh we have never found necessary or useful.

Gangrene, we have said, scarcely ever follows inflammation of the throat; and scirrhi of the tonsils, though mentioned as a consequence, are certainly rare. The tonsils we have seen often scirrhus, but never cancerous; and they have remained in the scirrhus state through a long life.

See Aretæus, Cœlius Aurelianus, Hildanus, Trallianus, Hoffman, Boerhaave, Le Dran's Operations, Wallis's Sydenham, and Fordyce's Elements, part. ii. Cullen's First Lines, i. 279. edit. 4.

ANGINA AQUOSA ŒDEMATOSA. Boerhaavii Aphor. 791. This is a species of dropsy, arranged by Dr. Cullen under ANASARCA, the second species, which arises from obstruction, occasioned by compression of the veins; see ANASARCA OPPILATA. It is called LOWERRIANA, being produced upon a dog by Lower's tying up the jugular veins, which brought on the angina aquosa that occasioned suffocation; see Sauvages' Nos. Meth. vol. i. p. 678.

ANGINA GANGRÆNOSA, called also *garotillo*, *angina maligna*, *epidémica*, *gangrænosa*, *ulcerosa*, *ulcusculosa*, *suffocativa*, ERYSIPELATOUS, ULCERATED, MALIGNANT, OR PUTRID SORE THROAT; *cynanche maligna* of Dr. Cullen.

This is a disease of great danger and importance. It is probably not a new one; but its nature and proper

treatment were seemingly obscured by the too common term of pestilential, and the farrago of remedies adapted to a name. The history is very accurately detailed in Dr. Cullen's Synopsis, where a chronological list of the authors who have treated of it is inserted.

It attacks like a slight inflammatory sore throat, though sometimes only a languor insidiously creeps on, with a little difficulty of swallowing; and, in the worst cases, even this is absent. The strength, however, rapidly sinks, the features fall, a ghastly paleness comes on, and death quickly follows. In slighter kinds, the course is not very different from that of the inflammatory species, though seemingly slight, with alternate chills and heats, pain in the head, &c. till the debility appears, when every other bad symptom immediately follows. Every sore throat, should, therefore, be carefully examined.

In the most active inflammations of the throat, white specks will sometimes appear on the velum pendulum or tonsils. If the inflammation is florid, the constitution robust, and the pulse firm, these spots may be disregarded. On the contrary, in some instances of the most malignant kind, no sloughs can be observed. The distinction must be taken from the colour of the inflammation. In the true malignant sore throat, the colour approaches rather to the crimson and the pink than the red; and sometimes a shade of brown, not far distant from the cinnamon, is mixed. The pain in swallowing is slight in proportion to the degree of inflammation; languor, listlessness, and indifference, are very conspicuous; and the features display the same want of fulness and tone: the eyes are red and watery. At this time the pulse will be sometimes apparently strong, but a slight attention shows that the strength of the stroke is apparent only: it throbs with a kind of convulsive weakness, rather than beats with a steady firmness. The tongue grows brown, the breath offensive, and delirium, at night, comes on: by day, a wandering is only observable. When there are sloughs on the throat, the edges are of a dark pink red; they are observed to cover, and sometimes they conceal a considerable loss of substance; they enlarge, become deeper, and the edges black. An ichor, or a thin acrid matter, is discharged from the nose or ears; the stools are thin and highly offensive. The fever is said to remit in the morning, but the remission is inconsiderable, and will never assist in the distinction, though it will sometimes lead to an insidious security.

Sometimes, from the beginning, exanthemata appear; and the putrid sore throat is frequently, if not constantly, an attendant on scarlatina: these soon assume a darker hue, and appear livid. The breath in the earlier periods is not affected, but a wheezing noise supervenes if neglected; and this, in the worst kinds, is succeeded by the shrill barking sound which has occasioned the Spaniards to give it the name of GAROTILLO. It evidently arises from the erysipelatous inflammation extending to the larynx, and is generally a fatal symptom. The eruptions have been described as favourable and critical: we have generally found them accidental, and only of use as an index of amendment, or of the disease increasing in violence and malignancy. In a disease which runs its course generally in less than five, always in seven days, no prognostic is to be depended on but a more florid appearance in the

throat, and a more healthy aspect of the edges of the sores.

The disease is epidemic, and attacks the active and robust as well as the infirm. We have not found the number of its victims greatly disproportioned in any period of life, in any situation or time of year. It is certainly infectious, though the infection is not active, or its influence very extended.

All evacuations are highly injurious; and an emetic, with which we are often directed to begin, sometimes operates with such violence as to debilitate greatly. If a stool or two be necessary, a clyster, or a very mild, quickly operating laxative, is alone admissible. After this the bark is to be given in active doses, with aromatics. Half a dram of the bark, with ten grains of aromatic species, should be exhibited every two hours. If it seems to produce strictures on the skin, and rigor, five or six grains of camphor, and three or four of true James's powder, (guarded by a little opium,) should be added to each dose. These may be washed down with a strong decoction of bark, sharply acidulated with either of the mineral acids. We may, however, remark, that in this disease the bark seldom disagrees.

The action of these remedies is greatly assisted by diet and gargles. Port wine should be given freely: it should indeed enter into every part of the food, and be drunk alone, cold. Even sleep is less necessary than bark and port wine; and should it continue above three hours, the patient must be awakened, for the loss of time cannot be regained. The quantity of the medicine and the wine must be regulated by the effect. If we gain nothing in the first thirty-six hours, we may depend on a fatal event: if we lose ground in twenty-four, our hopes will be inconsiderable. We have known women unaccustomed to wine drink two bottles within twenty-four hours, for more than a fortnight. The gargles should be of a strong decoction of bark, very sharply acidulated with mineral acids or with the strongest Cayenne vinegar, or some Cayenne in substance should be added; and they should be frequently used, or, as the patient is languid, injected with a syringe. Pepper-corns constantly bitten, and the saliva swallowed, we have often found highly useful.

These are the appearances, and such the practice in the more violent attacks of the complaint; and we have never seen an instance of it, when taken early and treated in this manner, in a constitution moderately strong, proving fatal. The same plan, less actively pursued, is adapted to the milder kinds. But even the mildest should not be treated with indifference.

In the worst cases, a palsy of the muscles of the throat has come on, and nothing could be swallowed. We must then inject nourishing clysters and port wine, alternately, every three or four hours, with a little opium: use a semicupium of a strong decoction of bark; and let wine and jellies be kept in the mouth as long and as frequently as possible. This plan has succeeded, in more than one case, in our hands; and in one of these the patient swallowed nothing for six days.

We have not mentioned, among the remedies, blisters, for authors are much divided respecting their effects; and many idle theoretical discussions have been indulged on the subject. They certainly have never been injurious, but we dare not say that they have ever

been advantageous. On a candid and dispassionate review of what we have seen, we can scarcely recommend them. The myrrh, also, we have not mentioned internally, or in gargle, because we think it too weak a minister to be trusted in emergencies, and it is unnecessary in slighter cases. Yeast, effervescing mixtures, and clysters, have not been sufficiently tried in circumstances so desperate; and, as the other remedies seldom fail, these are at least unnecessary.

See Aretæus de Causis et Signis Morborum, lib. i. cap. 9. Dr. Fothergill's Treatise on the Putrid Sore Throat. Dr. Huxham. Le Cat, Johnson, and Chomel on this disease. Northcote's Treatise on the Ulcerated Sore Throat. Dr. Percival's Essays. Dr. Fordyce's Elements; part. ii. Cullen's First Lines, i. 284. edit. 4.

ANGI'NA TRACHEALIS. In compliance with Dr. Johnson, and consonantly with our observations in a former article, we mention this species as a separate one, and distinct from that sometimes comprehended under this title by other authors. The croup we shall next consider under the appellation of *angina stridula*, and confine the present term to the *malignant angina*, extending to the trachea, or to that species of the disease in which the larynx and trachea are originally attacked. To this complaint authors have not, perhaps, paid due attention: it is indeed seldom an original disease; yet, within our own observation, it has appeared to be so. It is truly an erysipelatous inflammation, in contradistinction to the phlegmonic; nor does it materially differ in its treatment from putrid pneumonia, or *angina maligna*. We need not, in such instances, dread the power of the bark in inducing dyspnoea, but employ it freely with cordials. The only question is, whether blisters are more admissible or more effectual? From our own experience we cannot encourage their application; but they certainly do no harm.

ANGI'NA STRIDULA. This is the *cynanche trachealis* of Cullen; a disease that, for its singularity and fatality, has fixed the attention of pathologists and practitioners. We wish we could solve the difficulties, or direct a more scientific or successful method of cure than has hitherto been adopted.

The *cynanche* was the boast of Dr. Cullen, as a natural well established genus, under which the species were scientifically arranged. The subject of nosology we must, at a future period, consider; but we may now add, that self-complacency had never so baseless a foundation. The species agree in no one principle but affections of the parts connected with the neck. Is it a group of complaints in which the breath is affected? No: in the gangrenous sore throat, and the mumps, the breathing is free.—The swallowing? This is not affected in the malignant angina or the croup.—Inflammation? Scarcely any inflammation occurs in the mumps. Yet we mean not to undervalue nosology, or its great advocate. We think highly of both; and if there ever was a man to whom medicine was peculiarly indebted as a science, who, by enlarged and comprehensive views, has added to its value, its utility, and importance, THAT MAN WAS DR. CULLEN. Our pages will be an ample commentary on this text; but our eulogium is not the rash, hasty effusion of a *young* theo-

rist, but of a person who has for a long series of years brought his opinions to the test of practice. Near fifteen years have passed since his death, and no friendly hand has scattered flowers over his tomb, appreciated his genius, his talents, and his virtues. We have some reason to accuse his family of insensibility, or his pupils of ingratitude, did we not know that attempts had been made, in vain, to procure the honourable office of his biographer. But this is from our present purpose.

The ANGINA STRIDULA, (from *stridere*, to make a noise,) is called also *angina*, *membranacea*, *interna*, *perniciosa*, *polyposa*, *catarrhus suffocativus*, and *morbus strangulatorius*. It is chiefly a disease of children, and is distinguished by a difficult inspiration sounding as through a brass tube, harsh cough, with seldom any tumour in the throat, and no difficulty in swallowing. This definition differs from that of Dr. Cullen, who is a little warped by his adherence to system. A cold and a short cough precedes for some days, when the harsh breathing comes on, with little or no fever; sometimes suddenly, at others more gradually, increasing by degrees, till suffocation closes the scene. The other functions are scarcely disturbed. The pulse, at first a little harsh, or slightly quickened, in the progress becomes very rapid and low. The face, at first flushed, is in the latter stages livid, though sometimes full. The stomach and bowels are not apparently affected. The cough is dry, flaky substances are spit up, and the patient struggles with an attempt to discharge something solid from the trachea. The internal fauces are, in a very few cases, swelled and red. It is sometimes epidemic; seems more frequent in low, marshy situations than in more elevated spots; and peculiar to children, at least scarcely ever attacking those above twelve years of age.

The disease consists in a membranous substance, lining not only the trachea above its divarication, but also its minutest branches, though the larger parts of the tube are first affected. It has been considered as a spasmodic disease by some, as it attacks suddenly, and is relieved by the warm bath and *asafoetida*; and as inflammatory by others, who rest, with equal security, on the cough preceding, and the utility of bleeding. In the early period it is undoubtedly inflammatory, but this stage is short and transitory; the exudation soon commences, and the remedies for inflammation lose their efficacy. It may be perhaps asked, in what, then, does the disease in its progress consist? Certainly not in spasm, but in this peculiar exudation, of which we have scarcely any other example: and the more general ideas of spasm and inflammation have, we fear, misled practitioners in the treatment of the disease. The exudations, which are usually the consequence of inflammation, agglutinate contiguous parts, not in the form of a membrane, but of cellular texture. It is thus in the lungs when united to the pleura, and in every instance of adhesive inflammation. A preternatural quantity of mucus hardens in masses, but not in membranes; for the mucus of the bronchial glands in catarrhs and asthmas, never assumes a membranous form. In fact, the inflammatory effusion consists of the gluten of the blood diluted with the serosity: the croupy membrane is a peculiar secretion. The labours of physiologists have discovered lately a new ingredient in the blood, which they have called fibrin; which

concretes in a fibrous substance, sometimes membranous, and has even been suspected of possessing a portion of irritability. It is undoubtedly this substance which is effused; but why inflammation, at this particular period, should occasion the exudation of fibrin rather than of gluten; why this should occur at an age when fibrin is not peculiarly abundant; and why a portion of the blood, which contains the largest share of azote, should be separated at a time of life when this principle is in a small proportion; are difficulties that we cannot surmount. The chemistry of the animal fluids is in its infancy. We know not the effects of the "play of affinities" in the fluid parts of the system; and, by some unexpected combinations, azote may be separated in constitutions that appear to contain the smallest share of it. Thus we cannot detect sulphur in the animal system; yet we find it separated in the intestinal canal, and making a large proportion of the fluids of some malignant ulcers and cancers. The whole is at present involved in obscurity.

To detail the progress of a disease which generally goes on from bad to worse, or to estimate the period when nature can no longer bear up against the accumulations that obstruct respiration, would be useless: the distinction it is of more consequence to consider. The peculiar breathing is not the criterion of the complaint, for it occurs often in children without any bad consequence, and in persons of every age. Experience can see a distinction in the appearances which language cannot convey; but, in general, it may be considered as true, that the clangous inspiration if not relieved within twenty-four hours, or, if relieved, recurring within twelve, is of the croupy kind, especially in children under four years. The asthma of infants has undoubtedly been mistaken for croup; but in those we think the respiration is attended with some rattling noise, while in croup it is clear and shrill. See *ASTHMA SPASMODICUM*. Many cures have been reported of croup, which were certainly cases of this kind; for those who have been able to distinguish the disease, have repeatedly failed with the same remedies. It is not infectious, but it seems to prevail in particular situations; and in families it has affected all the children about a certain age.

We have said that it is for a short period inflammatory, and this we judge from the effects of active, decisive bleeding. If there be any truth in medical observation, a large bleeding, immediately on the attack, has cured the disease. At a future period scarcely any thing has succeeded, though a few victims have been rescued.

Emetics, topical bleeding with leeches, blisters, and purgatives, have been repeatedly tried, scarcely in any instance with success. We had long since determined to neglect these and to pursue an opposite method, viz. by a cordial and sudorific plan to endeavour to direct the morbid fluids to the surface, led by some relief apparently obtained by a quack medicine, which certainly had no other powers. This method would have been attempted, had not bold empiricism introduced another, viz. large and repeated doses of calomel. Even to very young children five or six grains are given every two or three hours, till a discharge of a green bilious matter comes on; and the relief, it is said, soon follows. We have some confidence in the reports we have received

of the success of this medicine, though in our hands it has failed; and the rapidity with which mercurials of all kinds break down the denser parts of the blood, renders it, in our opinion, a remedy of great apparent utility. The thin green bilious discharge seems an evidence of this effect. Strong mercurial frictions might perhaps be at the same time employed.

ANGI'NA ERYSIPELATOSA, MUCOSA, EPIDEMICA, ANGIGNOSA, EXANTHEMATICA. MUCOUS QUINSY. See SCARLATINA ANGINOSA.

ANGI'NA PAROTIDÆA. The *cynanche parotidæa* of Cullen; *catarrhus bellinsulanus*, *ourles*, and *orcillons*, of other authors. After a slight inflammatory fever, the parotid and maxillary glands swell sometimes rapidly, and to a considerable size; but they seldom suppurate, and the disease requires no particular remedy. The fever is decisive in its attack, and appears of a specific nature. What leads more strongly to this opinion is, that the swelling sometimes ceases suddenly, and is transferred to the testes in the male, and to the mammaræ in females. We have, however, seen it twice pretty generally epidemic among children, without observing either metastasis. Twice in adults we have seen an instance of the former, and the swelling yielded to the common remedies. In the neck, it has been usual to keep the part warm; to give nitre and purgatives, and to rub in mercurial ointment. Nothing is, however, necessary; and those who have been most neglected, have been soonest restored to health. Keeping the swelled neck warm is always improper; nor does there seem the slightest reason to suspect a translation to the brain. Gooche's Cases and Remarks, p. 74—76, and Appendix, p. 13. Cullen's First Lines, edit. 4, vol. i. p. 303.

ANGI'NA PHARYNGÆA. This species is particularly rare. It is described by Eller, *De Cognoscendis et Curandis Morbis*; and a case of it occurs in the third volume of the Medical Commentaries. The pain is felt behind the sternum, in swallowing only, and the breath is not affected. The cure is easy, and consists in swallowing slowly nitrous and mucilaginous medicines. The complaint is uncommon and trifling.

ANGI'NA SPASMODICA. See ASTHMA.

ANGI'NA PECTORIS. For the first account of this disease, the world is indebted to Dr. Wm. Heberden of London.

The patient is seized whilst walking, and more particularly if he walks soon after eating, with a painful sensation in his breast, extending to his arms; at first no further than the insertion of the deltoid muscle, but in succession to the elbows, wrists, and fingers' ends; the moment he stands still, this uneasiness vanishes: but, after this complaint hath continued some months, it does not cease so suddenly after resting; it will now come on even while the person is in bed, obliging him to rise every night for several months together. In some inveterate cases it hath been brought on by very trivial accidents, such as coughing, going to stool, by swallowing, speaking, or from any slight disturbance of mind. Sometimes, though rarely, it attacks while the patient stands or sits still. In some persons it is the worst in winter, in others during the summer season. When a fit approaches whilst the patient is walking, its duration is short; but if it comes on in the night, it will continue an hour or more. Sometimes, though

rarely, there are several days before any remission is manifest; and, during this time, the danger is imminent. The pulse is, at least sometimes, not disturbed with the pain, consequently the heart is not affected by it.

Persons of fifty years of age and upwards, of gouty habits, with short necks, and who are inclined to be corpulent, are the most subject to this disease; it is, though rarely, met with in those who are younger.

The fatal event is generally sudden: yet some continue affected with it for twenty years; and in some it almost spontaneously disappears.

The seat seems to be in or about the sternum, but always more to its left side than to any other part; and the pain is more common in the left arm.

The cause is most probably a spasm, or convulsion, as appears from its sudden attack and speedy departure, the long intervals of ease, the relief afforded by wine and spirituous cordials, its generally bearing the motion of a horse or carriage well, and its coming on in the night after the first sleep; at which time asthmas, the nightmare, convulsions, and other disorders attributed to the disturbed functions of the nerves, are peculiarly apt to return, or to be aggravated.

Dr. Parry has lately endeavoured to show, that the disease arises from an ossification of the coronary arteries of the heart; but, in general, it may be remarked, that it attends persons of advanced life, where such ossifications are not uncommon; and that we can perceive no connexion between the effect and the cause. If the functions of the coronaries were impaired, we may expect only a mortification, or a washing of that organ. In his dissections also, it has been observed, that, in the only case where ossifications were found, the disease was obscurely marked; while the others, more certainly cases of angina pectoris, offered no such appearance. In general, ossifications have been found near the valves, and in almost every portion of the heart or larger vessels; yet these are evidently effects only.

With regard to the cure, evacuations have been tried, but to no purpose; though wine and other cordials, taken at bed-time, will prevent or weaken the night fits, yet nothing does this so effectually as opium; ten, fifteen, or twenty drops of the tincture of opium taken at bed-time, will enable those patients to keep their bed until the morning, who have been forced to rise and sit up two or three hours every night for many months. A blister applied to the sternum, and kept open with nervous medicines, particularly the bark and valerian; and sometimes the preparations of copper seem to be most effectual; and, unless the disease be supposed to have vanished spontaneously, have cured it. Dr. Macbride advises issues in the thighs, with small doses of calomel; but this plan has either not been tried, or been unsuccessful. This quantity of opium, or more, may safely be continued as long as it is required. Dr. Bergius, a Swedish physician, says, that this disorder is a kind of spasmodic asthma, and that it is relieved by a solution of gum. ammon.  $\frac{3}{4}$  ss. in aq. puleg. vel hyssop.  $\frac{1}{2}$  ss. two spoonfuls to be taken two or three times a day. See the Lond. Med. Trans. vol. ii. p. 59. iii. 1. 37. Medical Obs. and Inq. v. 233. 252. London Med. Journal, v. 162. Memoirs of the Medical Society of London, 238. 306.

**ANGIOLOGIA, ANGEIOLOGIA**, (from *αγγειον*, *vas*, and *λογος*, *sermo*). **ANGIOLOGY**. It treats of the glands, lacteals, lymphaducts, nerves, arteries, veins, and other vessels; including their structure and distribution.

**ANGO'LAM**. It belongs to a new genus, not yet to be found in the systems, the *alangium*. It belongs to the natural order *myrtoides*, and is a polypetalous flower of the *decandria monogynia* class and order. A large tree growing in Malabar. It runs up to the height of one hundred feet, and is twelve feet thick. It is an evergreen; its fruit resembles a cherry, and is most delicious.

The expressed juice of the root cures the bites of serpents, discharges the water of dropsical swellings, and kills worms. Raii Hist. Plant. The species is that with ten petals; another with six petals is less valued: its fruit is healing; but the leaves infused in oil are applied to wounds, and the root is purgative.

**ANGO'NE**, (from *αγγω*, *to strangle*). A NERVOUS SORT OF QUINCY. Vogel defines it to be an acute stopping up of the fauces, without inflammation. The convulsive quincy, and hysteric suffocation, are enumerated among its species.

**A'NGOR**, (from *ango*, *to trouble*). A concentration of the natural heat of the body, causing a palpitatio of the heart and anxiety. In the beginning of a fever it is a bad prognostic.

**A'NGOS**, a VESSEL; a receptacle of humours. See **VAS**.

**ANGSA'NA**, vel **ANSAVA**, (Indian,) called also *draco arbor*.

It grows in the East Indies. The liquor which distils from a wound made in this tree is used as a medicine, when it is condensed into a gummy consistence. It is of a red colour, astringent, and is sold for dragon's blood. Raii Hist. Plant. Dale. It has not yet been reduced to its place in the vegetable system.

**A'NGU**. See **CASSADA**.

**ANGUILLA**, (from *ev*, and *χεμαί*, *to involve*, because it rolls itself in the mud). The **EEL**.

Eels that are met with in rivers, or other clear running waters, are the best; the liver and the gall are extremely acrid. Boerhaave says, that no fish has a more acrid gall; and that with a mixture of the galls of the *eel* and the pike, made into pills, he hath cured many rickety children with hard and swelled bellies.

The **TORPEDO**, or **TORPORIFIC EEL**, found in Guiana, in South America, if caught by a hook, violently shocks the person who holds the line; and the shock is communicated in a circle like the electrical. Hence it is called the **ELECTRIC EEL**. No shock is perceived by holding the hand in the water near the fish when it is neither displeased nor touched; but if it is angry, it can give a shock to a person at five or six inches distance. This shock is produced by an emission of electric or Galvanic energy, which the fish discharges at pleasure. On the death of the animal no such property remains, and then the Indians eat it.

**A'NGUIS**. *Serpens anguis, anguis coluber natrix torquata*, the **SNAKE**.

Our *snakes* in England, and those in other cold countries, the viper excepted, do not injure us with their bites. Their fat is as good as that of the viper.

**ANGUI'UM SENE'CTÆ**. The *exuviae*, or skins of serpents that are cast in spring; the slough or cast skin of a snake is as good. A decoction of it boiled in wine is said to cure deafness, pain in the ears, &c.

**ANGULA'RIS ARTE'RIA**, (from *angulus*, *an angle*). See **MAXILLARIE ARTERIÆ**.

**ANGULA'RIS MUSCULUS**. See **LEVATOR SCAPULÆ CL PATIENTIÆ**.

**A'NGULI O'CULI**, (from *angulus*, *an angle*). See **CANTHI**.

**A'NGULUS ACU'TUS TI'BIÆ**. The spine of the tibia, or the shin.

**ANGU'RIA**, (from *αγγος*, *a vessel*), so called because it resembles a cup. See **CITRULLUS**.

**ANGUSTA'TIO**, } (from *angustus*, *strait*). **ANXI-ANGU'STIA**, } *ETV*, restlessness in distempers. They also signify a narrowness of the vessels.

**ANGUSTIFO'LIA PLANTA'GO**, (from *angustum*, *narrow*, and *folium*, *a leaf*). See **PLANTAGO MINOR**.

**ANGUSTU'RÆ CORTEX**, **ANGUSTURA BARK**. This bark, at first imported in the year 1788, was supposed to be the production of a tree on the coast of Africa; but it is now found to come from the Spanish main. Mr. Bruce pronounced it to be the bark of a tree called *wooginos*, by which he was cured of the dysentery in Abyssinia; and having brought over some seeds, and planted them in Kew gardens, their product he calls **BRUCEA ANTIDYSENTERICA**, vel **FERRUGINEA**; but, in the Medical Commentaries of Edinburgh, 1790, they are, on comparison, proved to be very different. This bark is imported in pieces of six inches long, and one inch and a half in breadth. The epidermis is whitish, the substance compact, and the colour, when powdered, not unlike that of rhubarb. It is a powerful bitter, joined with an aroma, not much more pungent than cascarilla, having a portion of pure oil, which approaches in its nature to camphor. It seems also to possess a narcotic principle; and has been considered more powerful than the Peruvian bark, both as a tonic and antiseptic: the virtues reside more in its gummy than resinous extract; but both are extracted by warm water, together with the oily portion. The diseases in which this medicine has been employed are those in which the Peruvian bark has been useful. In intermittents it is generally inferior in efficacy; in low fevers, and those of the putrid kind, it has seemed superior. In head-achs, attended with fever, but arising from the stomach; in dysentery, and dyspepsia; it has been of great service. From various experiments, the Angustura bark seems to claim the highest rank as an antiseptic. An extract is made in the following manner:

Take four ounces of the Angustura bark, put it into a flannel bag of a conical shape, pour upon this boiling water, and repeat it till the filtering liquor has but little taste or colour. Let the infusion be evaporated by a gentle heat, and thirteen drams and twenty grains of extract, of the full flavour of the bark, containing two drams of resinous matter, will remain. See Brande's Experiments and Observations on Angustura Bark.

**ANHA'LDINUM**. An epithet of a corrosive, described by Hartman.

**ANHALTI'NA REMEDIA**, (from *anhelo*, *to breathe with difficulty*). Medicines which facilitate respiration.

**ANHALTINA A'QUA.** ANHALT WATER of the Brandenburg Dispensatory. Sp. vini rect. is distilled from turpentine, and twelve or thirteen other ingredients of the aromatic kind added; but a more elegant spirit of a similar nature may be obtained by mixing a proper quantity of the essential oils of rosemary, lavender, or sage, with the common oil of turpentine, and then distilling them from spirit of wine. This water is an excellent cordial.

**ANHELA'TIO, A'NHELO, ANHELI'TUS,** (from *anhelo*, to breathe short,) **PANTING.** A shortness of breath after strong exercise. In fevers, dropsies, asthmas, pleurisies, &c. there is always an *anhelitus*. To express this Hippocrates often uses the word *pneuma*; but the same term amongst the chemists signifies SMOKE, and also HORSE DUNG; this last is called, when hot, *cancerifericon*.

**ANHI'MA.** (Indian). An aquatic bird of prey in Brasil, larger than a swan. Its horn is esteemed an antidote against poison.

**ANHUI'BA.** (Indian). See SASSAFRAS.

**ANICE'TON,** (from *a*, privat. and *νικτω*, to conquer,) **INVINCIBLE.** An epithet for a plaster ascribed to Crito; an infallible remedy for the acores.

**ANICE'TUM.** See ANISUM.

**ANIDROS,**  
**ANIDROSIS,** } (from *a*, neg. and *ιδρω*, to sweat).  
**ANIDROTI,** } Without sweat.

**A'NIL.** See INDICUM.

**A'NIMA MUNDI,** (from *ανemos*, wind, spirit). The SOUL OF THE WORLD. The ubiquitarian principle of Plato, like Des Cartes' æther, pervading and influencing

all parts and places, and the archæus of Van Helmont and Paracelsus. In the works of the elder chemists and pharmacutists, it means a concentration of the virtues of bodies, by any means that can be supposed to develop their powers, as solution, distillation, &c. Thus we have *anima jaspidis*, aloes, and rhubarbari.

**A'NIMA PULMONUM.** A name given to saffron on account of its supposed use in asthmas. See CROCUS.

**A'NIMA HEPATIS.** The name of SAL MARTIS.

**A'NIMA ORTICULORUM.** A term for HERMODACTYLLS, &c.

**A'NIMÆ.** The VESICLES OF HERRINGS; are thus called because they are light and full of wind. They are supposed to be diuretic.

**A'NIMAL,** (from *anima*, life). All bodies endowed with life, and with a power of spontaneous motion necessary to support life, are called *animals*. Animals are thus distinguished in general from vegetables. But perhaps a more correct and scientific definition is the following:—An animal is an organized body, sensible, capable of voluntary motion, provided with a central organ of digestion. They are all capable of reproducing their like: some, by the union of the two sexes, produce small living creatures, and are called *viviparous*; others lay eggs, which require a due temperature to produce young, styled *oviparous*; some multiply without conjunction of sexes, *hermaphrodites*; and others are reproduced when cut in pieces, like the roots of plants, *animal plants*.

After man, all other animals have been divided into eight classes, in the following manner:

DAUBENTON'S DIVISION and CHARACTERS of the Eight Classes of ANIMALS.

Having a head.						The most part having no head.	
With nostrils.						Without nostrils.	
With ears.						Without ears.	
Two ventricles in the heart.		One ventricle in the heart.				The heart variously formed, or unknown.	
Warm blood.		Blood nearly cold.				A whitish fluid instead of blood.	
Inspiring and expiring air frequently.		Inspiring and expiring air at long intervals by lungs.			Admitting the air by gills.	Admitting the air by spiracula.	No apparent entrance or aperture to admit air.
Viviparous.		Oviparous.					
With teats.		Without teats.					
1st Ord. Quadru- peds.	2d Ord. Cetaceous Animals.	3d Ord. Birds.	4th Ord. Oviparous Quadrupds.	5th Ord. Serpents.	6th Ord. Fishes.	7th Ord. Insects.	8th Ord. Worms.
Four feet and hairy skin.	Fins and no hair.	Feathered.	Four feet and no hair.	Scaly with- out feet or fins.	Scaly with fins.	Having antennæ.	Having neither feet nor scales.

We shall add the Arrangement of CUVIER, which is in general preferred :

Animals with vertebræ.	{	Blood hot: heart with two ventricles.	{	Viviparous with mammæ.	Mammalia.
		Blood cold: heart with one ventricle.		Oviparous without mammæ.	
Animals without vertebræ.	{	With blood vessels.	{	Lungs sometimes with gills.	Reptiles.
				Gills without lungs.	
	{	Without blood vessels.	{	A simple spinal marrow without articulated limbs.	Molluscæ.
				A knotty spinal marrow <i>without</i> articulated limbs.	
				A knotty spinal marrow <i>with</i> articulated limbs.	Crustaceæ.
				No spinal marrow; no articulated limbs.	Insects.
					Zoophytes.

We may subjoin for its curiosity, perhaps from its scientific accuracy, that of M. VIREY; premising only, that he understands, by the great sympathetic or intercostal, a nervous system, not immediately and directly issuing from a brain, but, like the intercostal in the human body, composed of nerves from different sources.

Animals.	{	With two nervous systems, the cerebral and sympathetic:	{	With hot blood	Mammalia.
				With cold blood	Birds.
	{	With a nervous system surrounding the œsophagus, the sympathetic:	{	With a heart	Reptiles.
				Without a heart	Fish.
					Molluscæ.
	{	With nervous molecules; zoophytes.	{	Solitary	Shell-fish.
				United	Insects.
					Worms.
					Echinodermes.
					Hydri and infusory animals.
					Corals and ceratophytes.
					Madrepores and sponges.

Animal substances differ from vegetable in their chemical nature and changes they spontaneously undergo. Though not peculiar to the animal system, yet azote and phosphoric acid are their most distinguishing ingredients. The acid gives the distinguishing appearances to the earth which forms their basis, and the azote is the chief principle of the volatile alkali, formed during their spontaneous decomposition by putrefaction. Volatile alkali is contained in animal substances when entire, particularly in the blood, where it exists in an ammoniacal salt; but its proximate principles, azote and hydrogen, are more frequently found, and the alkali is formed during the decomposition. The same principles are found, also, in the gluten of farinaceous seeds, in mushrooms, and many other vegetable substances, particularly in the whole family of the cruciferæ; and a volatile alkali is separated from vegetables in various chemical processes. Hydrogen, its other principle, is more generally diffused through the vegetable and mineral kingdoms, and can scarcely be considered as an animal substance. Carbone, oxygen, and lime, the other animal radicals, are found in almost every substance.

There seems to be no peculiar animal acid. The zoonic and sebatic are probably the acetous: the acid of ants and of silk, the formic and bombyc, are acetous. The Prussic acid is still little known; and if any merit the appellation of animal acids, they are the phosphoric and the uric: of which the latter is only peculiar to the animal kingdom, and perhaps may at last appear to be the oxalic disguised by azote, as Proust supposes the bombyc acid to be. The other animal productions are fibrin, albumen, gelatine, mucilage, oils, sugar, resins, sulphur, and iron occasionally, perhaps accidentally, occurring. Gelatine and mucilage connect animal with vegetable substances, as they admit of the acetous fer-

mentation. With oxygen, mucilages form resins, of which there are few examples in the animal system, and the proportions are small. If we recollect rightly, the bile, the cerumen of the ear, and the urine, are the only instances in the human body.

The oils and fats of animals, like the gross oil of vegetables, are soluble either in water or in spirit of wine, by the intervention of a third body only, as mucilage or gum. The oils of animals differ from those of vegetables.—1. The finer animal oils are not, like the vegetable, procured by a moist, but almost always by a dry distillation, that is, by combustion; and hence all animal oils have an empyreumatic smell. 2. Though an acid is found in the fat of animals, yet in the distilled oils of animal matter a volatile alkaline property is found; but in those of vegetables there is always an acid. The volatile alkaline salts, therefore, contained in the oils of animals, render them more penetrating and stimulating than the distilled oils of vegetables. One drop of the ol. c. c. intimately mixed with the sp. vini. rectific. 3ij. is powerfully stimulant and sudorific. Independent of the oil collected in the cells of the adipose membrane, or that obtained by distillation, the decomposition of animal substances, by means of the nitrous acid, procures it in considerable purity.

The odorous matter of some animal substances, as musk, castor, &c. is, like the essential oils or resins of vegetables, soluble in sp. vini rectificati, and volatile in the heat of boiling water.

The gelatinous principle of animals, like the gum of vegetables, dissolves in water, but not in spirit or in oil. Like the gums, also, it renders oils and fats miscible with water. However, many animal juices differ greatly even in these general properties from the corresponding ones of vegetables. Thus animal

serum, which appears similar to vegetable gummy juices, and mingles with cold or warm water, concretes by heat into a solid mass: the heat necessary is about one hundred and fifty of Fahrenheit.

Animal substances become putrid much sooner than vegetable ones, and when corrupted are much more offensive. See PUTREDO.

Animal matter, burnt in the open air, is resolved, like vegetables, into soot and ashes, but with this difference, that no fixed alkaline salt can be obtained from the ashes, and no acid vapour accompanies the smoke. Exposed to the fire in close vessels, after the watery moisture, a volatile alkaline salt is obtained, together with an empyreumatic oil that is more fetid than that from vegetables.

ANIMAL BEZOA'RDICUM OCCIDENTA'LE. THE LESSER AMERICAN DEER.

ANIMAL BEZOA'RDICUM ORIENTA'LE. THE BEZOAR GOAT.

ANIMAL MOSCHI'FERUM. THE MUSK ANIMAL. See MO'SCHUS.

ANIMAL ZIBE'THICUM. See ZIBE'THUM.

ANIMAL KINGDOM. It is not our object to ascertain with precision the limits of this kingdom of nature, or to mark the various shades of distinction between animals and vegetables. It occurs in this place chiefly to notice the various medicines which it affords.

The *mammalia* chiefly furnish aliment; yet artificial teeth are formed from those of the *trichecus manatus*: castor and civet from the *viverra zibetha* and *castor fiber*; musk from the *moschus moschiferus*. The various species of *cervus* afford a nutrient jelly from their horns, and formerly the volatile alkali was also prepared from them, though now supplied by bones. The milk of the cow, the goat, the mare, and ewe, are well known; and the suet of the sheep, and the lard of the hog, need scarcely to be noticed. The morbid concretions, the bezoars, are not at present employed; the elk's hoof is disregarded; the bile of the ox and sheep seldom prescribed; and the gastric juices chiefly used as an external application.

The *physter macrocephalus*, from the cetaceous tribe, furnishes the *sphermaceti*, now styled adipocire; and the different species of sturgeon, from their air bladders, the *isinglass*. The oil which spontaneously separates from the liver of the pike (*esox lucius*) is used in obfuscation of the eyes; the oil from the liver of the cod-fish in rheumatism.

Among the *amphibia*, the *rana esculenta* is nutritious; and the *rana bufo*, it is said, has been used in cancers, by sucking the venom. Several of the *lizards* are supposed to possess medicinal powers. The *l. agilis* has been used as a remedy for cancers; the *l. scincus* as an aphrodisiac; and the flesh of the *l. iguana*, like that of some of the whales, has been suspected of exciting to action the latent venereal poison.

Of *insects* we shall on a future occasion treat more at length. See INSECTA. The *vermes intestina* furnish the *lumbricus terrestris* and the leeches; of the *mollusca*, we employ only the *sepia officinalis*, and the *limax maximus terrestris*; of the *testacea*, the *ostrea edulis* and *maxima*, and the *helix pomatia*; of the *lythophites* the madreporae, the coralline, the corals, and the sponges.

ANIMALCULE. A diminutive of the word *animal*; that is, they are such little creatures as require to

be viewed through glasses to discern them distinctly. Rain, snow, and dew, contain them in great numbers. In boiled water they sometimes revive.

The animalculæ in a fluid are generally collected in a mass; if disturbed, they separate, as fish in a pond, and continue for a time distant from each other. They follow the fluid to the last drop, and then seem to struggle and die; after their apparent death, on adding water, they revive. When seemingly dead, they are very flat; but soon recover their plumpness when revived. They are destroyed by the slightest atom of oil of vitriol; of solutions of common salt, salt of tartar, and sugar: urine and blood are equally fatal.

In short, animal life abounds so copiously, that wherever a nidus occurs, its peculiar animals are found; but in this place we must consider them only as connected with medicine. The animalcules discovered by Lewenhoeck in male semen, encouraged physiologists to suppose that they had unravelled the mysterious subject of GENERATION. More mature reflection and repeated observation have, however, dissipated the phantom, as we shall see under that article. Animalcules have also been considered as the causes of various diseases. Linnæus's Dissertation on the fifth volume of the *Amœnitates Academicæ*, entitled *Exanthemata Viva*, contains almost all the facts dispersed in various authors on this subject; and Langius has with equal anxiety reduced almost every disease to this cause. The complaints enumerated by Linnæus as owing to animalcules are, itch, dysentery, hooping-cough, small-pox, measles, plague, and syphilis. With respect to dysentery the argument is curious: in dysenteric stools, animalcules were found, and these animalcules were only killed by an infusion of rhubarb. Unfortunately, rhubarb will not cure dysentery. At present it is doubted whether even the itch is owing to animalcules.

A later idea of a disease from animals is that of Mr. Adams, who derives cancer from a species of *tenia*. His arguments are at least specious, and they will be considered in their proper place. See TÆNIA and CANCER.

See Philos. Trans. Abr. vol. iii. Dr. Hook's Micrographia.

ANIMA'LE DIPPE'LII, O'LEUM. DIPPEL'S ANIMAL OIL.

This is a common animal oil highly rectified: the number of rectifications required is in proportion to the former state of the oil: seldom less than six are necessary. It must be closely kept from the access of the air.

Animal oils thus rectified are thin, limpid, and of a subtle, penetrating, not disagreeable smell and taste. They are antispasmodic, sedative, and diaphoretic, in doses, from five to thirty drops. Hoffman speaks highly in their favour, observing, that one dose excites sweat, and supports it for twenty-four hours without languor or debility; and that if twenty or more drops are given on an empty stomach, six hours before the accession of an intermittent fever, they frequently remove the disorder: in chronical epilepsies and other convulsive symptoms, especially if given before the usual time of the attack, and preceded by proper evacuations, they are effectual.

They lose much of their quality by keeping.

All empyreumatic oils dissolve in *sp. vini rect.* and the more they are rectified, the easier is their solution, a circumstance in which they differ from essential oils,

which, by repeated distillations, become more difficult to dissolve.

ANIMA'LIS FACULTAS. See FACULTAS and ACTIO.

ANIMA'LIS MO'TUS. ANIMAL MOTION.

This is the same with muscular motion, and is divided into two species sufficiently known, voluntary and involuntary. See MUSCULUS.

ANIMA'LIS SPIRITUS. ANIMAL SPIRITS. See CALIDUM INNATUM.

ANIMA'TIO, (from *animo*, to give life, to animate). ANIMATION. The particular effect produced by the vis vitæ in all animated bodies, by which life is begun and supported.

A'NIME, so called from its refreshing odour. The Portuguese corrupted the word *anime* into *anime*.

The GUM ANIME is also called RESINA ANIME, and *courbaril rezina*, *aminea*, *animum*. By Piso the tree from whence it is obtained is called *jetaiba*, by the Indians *courbaril*. *Hymenæa courbaril* Lin. Sp. Pl. 537.

The gum anime is a transparent, yellowish white, resinous gum, obtained from a large tree in Brasil, New Spain, and the East. The latter Dioscorides calls by the names *myrrha* and *minæa*; but in our shops we have no other than the American kind. The small tears are the purest. It hath but little taste, though to the smell it is very agreeable. It easily breaks between the teeth; but if chewed for some time, it softens and becomes adhesive. If it is laid on a red-hot iron it immediately melts, inflames, and burns quickly away, leaving only very little white ashes.

It dissolves in sp. vini R. but is very little affected by water, except in distillation, when a part of its flavour and a small quantity of oil rise. The Brasilians are said to use it in fumigations for pains and aches from cold; for palsy and contractions. With us it is esteemed diuretic. The dose is ʒi. The gum copal is often sold for it.

ANIMELLÆ. The glandules under the ears, and under the lower jaw, called *lactinia*.

ANIMI, et ANIMÆ DELIQUIMUM. See LIPOTHYMIA.

ANIMIFERA A'RBOR BRASILIA'NA. See COURBARIL.

ANIMUM. See ANIME.

A'NIMUS, (from *ανemos*, wind or spirit). THE MIND. The body and the mind reciprocally affect each other; whatever invigorates the body, renders the faculties of the soul proportionably active and strong: what depresses the strength lessens the spirit, the resolution, and the more active intellectual faculties.

The circulation of the blood not only unites the soul with the body, but also governs and directs its operations; with the circulation of the blood, the animal and vital functions continue: they vary, and cease to be, according as the circulation varies or ceases. To preserve, then, the faculties of each, we must attend to the health of both.

The regulation of the mind is consequently a subject of the highest importance, and must be considered at some length; both as it affects individuals adapted for different employments, as necessary to the preservation of health, and as a means of alleviating disease, and assisting the powers of medicine. The *medicina mentis* has not, perhaps, obtained a sufficient share of attention;

and the few dissertations by Hoffman, Boerhaave, and Gaubius, have scarcely elucidated so intricate a subject.

It has been long since observed, that the most furious and courageous animals possessed strong fibres, a rich glutinous blood, and solids remarkably firm. The bones of the lion are said to be capable of striking fire with steel. These corresponding states of mind and body are supported by large supplies of animal food; and we animate the spirit of cocks fed for combat, of horses for speed, and of pugilists, by food of a nourishing power beyond the usual standard, which will afford strength, without overfilling the vessels.

A more calm and steady exertion of mind, a collected coolness, and an accurate discrimination of circumstances, in general similar, are connected with a very different state of body. The fever, excited by high diet, will not fit a person for duties of this kind. The sleep must be calm and undisturbed; the stomach not oppressed with crudities; the vessels not overfilled; the secretions neither obstructed nor preternaturally propelled. It is the state in which the student will best succeed; it is that to which the gamester, with unre-mitted attention, brings his constitution; and it is that perhaps most consistent with the best state of the intellectual faculties. Yet a habit of study cannot be long indulged with perfect impunity. This regular co-operation of body and mind is disturbed by the late hours which sometimes study demands; by the inactivity which persevering attention occasions. To the regular, calm performance of the functions succeeds from these causes a mind agitated and irritable; a stomach loaded with flatulence; bowels oppressed by accumulations. The powers of the mind are heightened to unusual quickness, and the body seems to want the activity thus diverted to other purposes. Yet the mind is a considerable gainer by the exchange. Fancy is more alive; analogies, remote and in general unperceived, become obvious; the imagination active, embodies airy nothings, and gives form, shape, and semblance, with hues more vivid than nature would own. The body, however, sinks under the exertion; and the irritable, sleepless, jaundiced, student, is the prey to the natural ills in consequence of his own irregularities, and to those which his imagination, thus exalted, portrays; happy to lose them in insensibility, or to exhibit an example how low human intellect can sink, as well as to what a height it can soar.

Indolence, combined with free luxurious living, gives another turn to the intellectual faculties. The vessels overloaded, produce languor, an incapacity for exertion, and at last a real, unconquerable debility. In this state, too, the mind equally suffers. Listlessness, inactivity, and lethargy, come on; the mind and body, equally torpid, sink together, and no cause of debility produces effects so difficultly subdued. Abstinence, even conducted with caution, occasions fainting; exercise is attended with the most distressing fatigue; and the abridgment of the long protracted slumbers induces even a worse languor than it was intended to relieve. An entire loss of sleep and of appetite, as well as of memory, and sometimes of reason, are the consequences.

Great exertions of mind and body are not attended with effects so fatal. If united, they seem scarcely injurious. Exertions of body alone, if regular occasional sleep is allowed, do little harm; and exertions of mind,

though strong and long continued, with moderate attention to hours of relaxation and rest, are not very injurious. The sailor and the mathematician are, perhaps, the persons who afford the strongest examples of each, and both have been remarkable for longevity.

The indulgence of passions, in every instance, undermines the constitution. The present subject confines us to mental passions. Anger, in excess, is a short madness, and unfits every man for careful enquiry and examination. Fear deprives us of our resources, and grief depresses every bodily function. Even joy, by extreme animation, has been fatal; and love, absorbing every other feeling, has, even when successful, been little less injurious. In short, every passion should be kept in due subordination, and regulated by reason and judgment.

We are thus brought to the next part of our enquiry—the regulation of the mind, as necessary to the preservation of health. The Almighty, when he gave us passions, bestowed also reason and judgment. By the due subordination of the former to the latter we obtain the chief good, *mens sana in corpore sano*. Yet it is with passions as with other causes of disease; they are hurtful only in excess. They are given to vary the dull uniformity which, without them, would ensue; to agitate the stagnant lake, which might otherwise become putrid and injurious. Our hopes, our fears, our joys, and sorrows, become useful stimuli to the intellectual system, as wine, and sometimes high foods, to the material. The torpid misanthrope, and the most strictly temperate men, are seldom healthy, or long lived. The principle within us, which regulates our systems, which corrects our deviations, and urges us to the supply of our wants, languishes for want of action, as the muscle no longer exercised loses its power. In short, our frame is adapted for action: let the causes of activity cease, and we can no longer exist. Let not this be considered as the language of Brunonianism, or the apology for excess. We disapprove of each: but a man may vary his habits without becoming a glutton or a drunkard; and may speak the language of common observation, without being wedded to a sect.

The regulation of the mind is of great importance in a studious man. The hour of sleep should not approach, while the mind is irritated by study. A calm serenity should be allowed to steal on, by light conversation, or by works which engage the attention, without mental exertion, before the time of retiring, and that time should not be protracted beyond eleven. During the times of study, the mind should never be forced to labour. It is sometimes less fitted than at others; and it often happens that the period of the best health is not that of successful study. The mind is then seemingly too much alive for confinement to a single subject, and will bend with greater ease when a little bodily fatigue has checked its too soaring flights. The studies also should be varied: few men studied more than Lord Kaimes; yet few preserved the mental powers so little weakened to extreme old age. This he owed to the variety of his studies, and to mixing them with the affairs of common life. A student was supposed to be above these; but he will gain little in the estimation of those “whose praise is fame;” he will gain little in mental or corporeal vigour for being so. Perhaps a student should be abstemious: this is, indeed, ne-

cessary, unless he combines bodily exercise with study; but he should certainly avoid studying soon after his meals, however slight they may be.

An important regulation of mind, particularly to the student, is the power of turning to a different subject, from that which engages his attention, without confusion or difficulty. This power few possess, but it is not difficult of attainment. It chiefly consists in having clear ideas on every subject, and declining any, until reflection has given that clearness, which enables us to see at once the whole of it with its various bearings. When this is attained, it is only necessary to avoid hurry. If a new subject is started, a few minutes' delay will prevent confusion; and, before custom has made a change common, the time allowed for the mind to resign one, and resume the other, should be enlarged. By habit, as usual, great facility in the process will be acquired, and it will seem intuitive. A very convenient power which may perhaps also be easily acquired is, that of employing the mind at once on two subjects of unequal importance; to talk, for instance, on common topics in general company, while the mind pursues some abstruse and intricate reasoning in its own recesses. This, we believe, is attained only by exercise and experience.

The regulation of the mind is of great importance in alleviating disease, and assisting the power of medicine. The effects of diseases purely corporeal, on the mind, are singular. In hectic, for instance, confidence of returning health constantly prevails, notwithstanding the hasty approaches of debility in every form. In syphilis, where there is no real danger, the mind is in as great a degree depressed, with an equal confidence of not surviving. In some fevers, the depression is so great, and the certainty of dying so strongly fixed, that the patient looks on the person as his worst enemy who foretells a different event. We might pursue this connection between the mind and body in a great variety of diseases. We mention them as instances only, to render the directions for the management more easy. Of the confident state of mind little need be said; yet this confidence must be sometimes lessened, when the arrangement of worldly affairs is necessary. When the mind is unreasonably depressed, ridicule and argument are equally cruel and misapplied. To reason with a madman is ridiculous; and the mind is partially deranged, which admits such unreasonable fears. The best method is to admit the danger, but to magnify the power of medicine; and, if any instance of recovery can be found in similar circumstances, ostentatiously to point it out. Mental impressions, except in very particular complaints, are by no means very permanent. They will in time lose their power; but, unfortunately, in many instances this power is retained till the constitution has received irretrievable injury.

The operation of medicines is sometimes assisted in chronic cases by exciting hope, and placing the completion of the expectations at a distance. If, by the relief of a troublesome symptom, one step can be gained, it will give a confidence which will materially assist the future progress.

Cheerful conversation, where the strength will permit, is of great importance in amusing the mind. The complaints, however, should not form the subject, nor should it be unkindly disregarded. When it unavoidably recurs, the conversation should be dexterously shifted:

not, as if that topic was forbidden, but as if it was not of importance, or because something more interesting offered. In general, patients should have sufficient power over their minds to prevent irritation from little inconveniences or disappointments, that must occasionally happen from the failure of their medicines. The calm, well-regulated mind possesses considerable advantages over the hasty, the fretful, and impatient. The one will recover in the most apparently desperate circumstances; the other will yield to diseases, scarcely in themselves dangerous.

ANINGAIBA, (*Indian*,) *Brasil. arbor aquatica*. The genus has not been ascertained. It seems to belong to the families of the *balisiers* and *aroids*.

The bulbous roots of the aquatic species are used for fomentations against inflations of the hypochondria. Of that species which is found in the woods, the leaves are bruised and applied as a general remedy for healing ulcers. Raii Hist. Pl.

ANISATUM, (from *ανισον*, *aniseed*). A wine in which aniseeds are infused.

ANISCALPTOR, (from *anus*, the *breech*, and *scalpo*, to *scratch*). See LATISSIMUS DORSI.

ANISUM, ANESUM, ANICETUM, ANISE. It is the *pimpinella anisum* Lin. Sp. Pl. 379. *Anisum herbariorum*. COMMON ANISE.

The common *anise* is a native of Egypt, Crete, and Syria: cultivated in the southern parts of Europe, and grows in our gardens in England; but it does not arrive at any great degree of perfection with us. The seeds only are used in medicine: those which are produced in Spain are smaller than those collected in other countries, and are generally the most esteemed.

Aniseeds have an agreeable aromatic odour, and to the taste they are gratefully warm, with a degree of sweetness; they are much used in flatulent complaints, and a scruple of the powder has been given for a dose, and in spasms of the bowels: they are also moderately anodyne, diaphoretic, diuretic, and discutient; an infusion of them in water moderates the thirst in a dropsy, and abates the diarrhoea; the fume received through the nostrils is said to abate head-ach; they promote an appetite, and check convulsive coughs, when a flatus and coldness in the stomach are the causes. They are supposed to increase the milk in nurses. Geoffroy says the odour is perceptible in that fluid. Cullen's Mat. Med.

Those who are offended with the seeds may employ the tincture, for the spirit in some measure covers their flavour.

Water and spirit of wine both completely extract the virtues of aniseeds; but in distillation very little of the seeds are carried over with the spirit; however, after its evaporation, a powerful and agreeable extract remains.

Angelica seeds are added to improve the flavour of those of the *anise*, in the compound water of aniseeds. This water is apt to be milky if drawn so low as directed in the dispensatory: it has been considered an elegant cordial stomachic medicine; a glass of it assists digestion after full meals, and when vegetables have been too freely eaten.

Along with the water in distillation, their essential oil, called by Van Helmont *intestinorum solamen*, arises to the quantity of  $\frac{3}{4}$  i. from  $\frac{1}{2}$  iii.; it possesses the taste, smell, and all the virtues of the seeds in the

highest perfection: it congeals when the air is not sensibly cold into a butyraceous consistence: so that the water in the refrigeratory should rather be warm, particularly towards the end of the process. The dose is from ten to thirty drops.

This oil is also obtained from *aniseeds* by expression; it is of a greenish colour, grateful to the taste, and strong of the seeds, of which, if sixteen ounces are lightly moistened by exposure to the steam of boiling water, about an ounce of oil may be obtained from them. This oil is gross, insipid, and inodorous, similar to the common expressed ones, with a part of the essential oil of the seed, on which its flavour depends. If this expressed oil is digested in rectified spirit of wine, the essential oil is extracted from it; or if it is distilled in water, the essential oil rises and leaves the other behind. The gross oil seems to reside in the kernel of the seed, the essential in the cortical part.

ANISUM INDICUM, *Stellatum*; *Sinense*; *Phillipense*; *Badian Semen*; *Feniculum Sinense*; *Cardamomum Siberiense*; *Zingi*. INDIAN OR STELLATED ANISE. It is the produce of a small tree which grows in Tartary, China, and the Philippine islands. The husks contain the chief of the flavour, which is the same as that of the common *aniseed*, but not so fiery: if they are digested in spirit of wine, they yield a most acrid resinous extract. The seeds afford much essential oil by distillation in water, which is thinner, more limpid, and more fragrant than that from the common sort.

The seeds of this species of *aniseed* are not yet common in the shops, though they are deserving of a preference to those in use. To the virtues of the common *aniseeds* they are supposed to add an expectorant power, and to be useful in atonic diseases of the lungs. Added to tea they make it more grateful and less injurious. The dose of the powder is  $\frac{3}{4}$  ss. In infusion  $\frac{3}{4}$  i. is added to a pint of water.

ANISUM FRUCTICOSUM GALBANIFERUM;—*Africanum fructescens, folio, et caule vere caruleo tinctis*. See GALBANUM.

ANNETESTES. So Paracelsus calls the Galenists, because he thought them ignorant of the causes and principles of things.

ANNO'RA. See OVORUM TESTÆ ET CALX.

ANNO'ATIO, (from *annoto*, to *mark*). The very beginning of a febrile paroxysm, called also the attack of the paroxysm. There is another *annotatio* or *epistaxis*, proper to hectic fevers soon after eating: in this there is no previous shivering.

ANNUE'NTES MUSCULI, (from *annuo*, to *nod*,) so called, because they perform the office of nodding or bending the head downwards. See RECTUS INTERNUS MINOR.

ANNULA'RIS CARTILAGO; is thus named from its shape, *annulus*, a *ring*. See CRICOIDES.

ANNULA'RIS DIGITUS. The ring-finger, or that next to the little one.

ANNULA'RIS VENA. The vein betwixt the ring and little finger.

ANNULA'RES LIGAMENTS, the name of those ligaments which confine the tendons of the carpus and tansus.

ANNULA'RIS MUSCLE. Sphincter ani.

ANNULA'RIS PRO'CESS. A protuberance of the medulla oblongata.

A'NNI/TEMPORA CONSTA'NTIA, vel IN-CONSTA'NTIA. CONSISTENT SEASONS, such as keep their usual temperature. Or INCONSISTENT SEASONS, when the weather is unsettled.

A'NNUS A'MADIN. LONG LIFE.

A'NO, *ανω*, UPWARDS. ANOTHEN. The superior parts. Emetics are thus called, as purging medicines are called *κατω*, downwards.

ANOCATHA'RTICA, (from *ανω* upwards, and *καθαιρω*, *purgo*). Medicines which purge upwards, as emetics.

ANOCHEI'LON, (from *ανω*, and *χειλα*, a lip). THE UPPER LIP.

ANOCCE'LLA. See CÆLIA.

ANO'CHUS, (from *ανεσχειν*, to retain). A stoppage of the intestinal discharge.

ANO'DMON, (from *α*, neg. and *οδμν*, a smell). WITHOUT SMELL. It stands opposed to fetid.

ANO'DUS. A word used by chemists for what is separated from the nourishment by the kidneys. The Greek word *ανodus*, *anodus*, (from *α*, neg. and *οδς*, a tooth,) signifies toothless.

ANO'DYNA, (from *α*, neg. and *οδυνν*, pain).

ANODYNES are medicines which ease pain and procure sleep. They are usually divided into three sorts, viz.

1. PAREGORICA. *Παρηγορεω*, *mitigo*, called also *anetica*. PAREGORICS, or such as assuage pain.

2. HYPNOTICA, *υπνορεος*. HYPNOTICS, or such as relieve by procuring sleep; *υπνος*, *somnus*.

3. NARCOTICA. NARCOTIC, or such as ease the patient by stupifying him; *ναρκωω*, *stupefacio*.

These divisions are not however correct, as there is no distinction between paregorics and hypnotics, except in degree; nor is there any evidence of the stupeficients acting differently from the latter: it would, at least, be a difficult task to ascertain where the one order begins, and the other ends. We would suggest a more natural and convenient division, viz. narcotics and irritants; the first to be again divided into opiates and stupeficients; the second into medicines which excite new motions, or those which remove sources of irritation. We thus include anodynes of every kind.

Though we cannot accurately discriminate between the opiates and stupeficients in their respective lists, where they approach near to each other, we can distinguish them in their extremes; and may instance, as examples, opium and hemlock. The opium, we know, is taken from the poppy; but its natural order, the *rheades*, affords no other medicine. The *umbellata* contain the hemlock and the dropwort; and the *solanaceæ* plants of the strongest narcotic powers, *solanum*, *digitalis*, *hyoscyamus*, *datura*, and many others. From other classes of plants we find the wolf's bane, (*aconitum napellus*,) flammula Jovis, *lactuca virosa*, *laurocerasus*, (*prunus laurocerasis*,) camphire, *laurus camphora*,) *agaricus muscarius*, *coccus Indicus*, *lolium temulentum*, (*l. spicis aristatis*,) and the Indian hemp, *cannabis sativa*. Chemistry gives us the oil of wine, nitrous æther, wine, and ardent spirits. All these seem to act in a way somewhat similar; viz. on the nervous system through the medium of the stomach, and perhaps differ only in degree; for the hemlock and the henbane, in moderate doses, seem to produce easy and quiet rest.

What change is produced in the nervous system by

VOL. I.

these medicines, or the opposite class of stimulants, we cannot in this place determine, because it would anticipate the subject. We may however observe, that in animals styled *cerebral* by Virey, (see ANIMAL,) the whole nervous system communicates with the head, and that the stomach is the organ by whose nerves the head is most readily affected. A small sedative power, applied to a nerve, has little influence beyond the nerve itself, and the organ to which it is sent; but the same degree of activity exerted on the stomach, produces effects more extensive, which are soon communicated to the brain and the whole system. Of the change in the nerves from these medicines we know little. It is highly probable, that an active fluid, analogous to the electrical or Galvanic, gives them their peculiar power; that its activity is confined to the nervous fibril, which, in its minuter ramifications, is accompanied by a non-conducting sheath or coat. At the extremities only is the nervous fibril free from this impediment, and in the stomach are these extremities chiefly accessible. The power, then, whatever it be, in sedative substances, which occasions this diminished action, most powerfully affects those nerves, and is from their constitution immediately communicated to the brain, diminishing or destroying its functions.

The system of Dr. Brown has occasioned a considerable change in the language of pathology and therapeutics, by the distinction which he introduced between direct and indirect stimulants. In this place it is sufficient to hint at the difference of language, because it is apparently supported by stimulant powers, which, in the greater number of anodynes, are at first obvious. It has been supposed by sounder physiologists, and more accurate observers, that these substances contain a stimulant with the sedative power, and that the former is more quickly exerted than the latter. This idea is not however very probable, both from the great dissimilarity of the two principles, and that the previous stimulant effects are disproportioned to the sedative, while many sedatives seem to produce no previous stimulus. Both in the arterial and nervous systems we have found great reason to suspect, that *irregular* action has been mistaken for *increased* action; and from the effects of sedatives, we very generally see irregular action only. This principle we shall have occasion to develop in explaining many parts of the animal economy. In the question before us we may instance the most common sedative, when in excess, because it is preceded by the most violent stimulating effects—we mean ardent spirits. While every artery in the body seems to act with increased energy; while the more violent passions are animated to phrensy, the voluntary muscles are certainly weakened during its action. The other intellectual functions are no longer exercised. The mind and body, even in the moments of fury, lose in many respects their power. If we are rightly informed of the effects of the Indian intoxicating powers, even in the moments of phrensy, partial debility is apparent, and, in the action of opium, we find very quickly irregular wanderings of the mind, though sometimes accompanied with a quicker or somewhat fuller pulse; and, in general, it will be very difficult to discover in this latter medicine a real stimulating power. When we consider its use

S

in inflammatory diseases, we shall show that it is seldom dangerous from its stimulus. The foxglove, and some others of the *solanaceæ*, seem to have no stimulating effect: they are purely sedative, and act as such on the arterial and nervous system; but it is doubtful whether they are truly anodyne or hypnotic.

A tendency to sleep is constantly produced in situations where we cannot readily trace the cause; viz. after a full meal. Whether, in the process of digestion, some gas of a sedative nature is evolved; or whether, as former physiologists have supposed, the pressure of the stomach on the descending vessels occasions a greater flow of blood to the head, is uncertain. Each cause may have some influence. For this reason it is needless to observe, that anodynes should not be given after a full meal: they are at least unnecessary; yet custom has long established the innocence, if not the utility, of the fumes of tobacco in such circumstances.

The *inirritants*, the second class of sedatives, are as various as the causes of irritation they are designed to remove. Extraordinary action, in any part, is relieved by blisters and friction; and, in some instances, well managed conversation, by inspiring hope, confidence, or cheerfulness, will produce sleep. Mental irritation is also soothed by exciting a less distressing series of thoughts; by melodious strains; by light narratives; by repeating verses or numbers; by watching, in imagination, corn waving in the wind; or roving, in fancy, through well known streets and roads. All these produce new motions, and less active ones, so that natural sleep soon follows. The regular movement of a coach, and, not to speak indecorously, the drawling voice of a dull preacher, will have the same effect.

We remove irritation of the nerves by the use of the pediluvium; but for this purpose it should be long continued, and the water not very warm; at about 98° of Fahrenheit it may be continued for more than half an hour. Irritation of the stomach may be removed by drinking cold or warm water. The irritation of too pure an air may be avoided by sleeping in a lower or more marshy situation, abounding more with hydrogen: thus asthmatics sleep better in a less elevated spot; and hectic patients have certainly slept sounder in the neighbourhood of a stable. Vapours of nitrous æther, and of hops, scarcely belong to this head; but perhaps their powers have been greatly exaggerated. Cold has been considered as a cause of sleep: it is certainly a cause of death, beginning with torpor; but slight degrees of cold are highly inimical to rest. Nitre, which cools the system and checks inordinate circulation, seems sometimes to occasion sleep by this operation; and camphor, in a way less obvious, seems, in febrile cases, to act as an hypnotic.

A great inconvenience resulting from opiates is a languor and dizziness on the following morning, similar to what results from taking ardent spirits or wine in excess. In some cases the cicuta seems to act as an anodyne, without the same consequences; and a preparation of opium by a surgeon of Lancaster, appears to affect the head very slightly after its operation. This is partly owing to its being a watery, rather than a spirituous, solution; and a tincture from wine of weak spirit is scarcely inferior. The correctors of opium we must consider under that article. See OPIUM.

ANO'DYNA. INDOLENCE, or absence from pain. Synonymous with *Anæsthesia*.

ANO'DYNUM. Also ANTIPODA'GRICUM, BALS. The ANODYNE BALSAM.

Bates's anodyne balsam consists of linim. sapon. ℥ i. tinct. theb. ℥ iv. m. Bateman's drops are made in the same way, only with a weaker spirit, and tinctured with aniseeds.

BALS. ANODYN. GUIDONIS, contains tacamahacæ pulveris terebinthinæ Venet. āā p. æq.

A retort is filled to nearly two-thirds of its capacity, and the oil distilled with a fire gradually increased: The red oil swims on the water, and must be separated, but differs little from other empyreumatic oils. If two parts of opium and eight of soap are digested in 48 parts of spirit of wine, adding to the strained liquor four parts of camphor and one part of oil of rosemary, an excellent anodyne balsam will be obtained.

ANO'DYNUM MINERA'LE. See NITRUM, and NITRUM STIBIATUM.

ANO'DYNUS FOTUS. ANODYNE FOMENTATION.

R. Capit. papav. contus. ℥ ij. Flor. sambuc. et flor. chamom. āī ℥ i. coq. in aq. font. ad ℥ ij. et colantur, adde acet. accerrim. ℥ vi. aq. ammoniæ ℥ i. m.

ANŒ'A, ANOI'A, (from α, neg. and νοος, the mind). STUPIDITY. See AMENTIA.

ANOMA'LA, ANOMALOUS, (from α neg. and ομαλος, equal or smooth). UNEQUAL, IRREGULAR.

ANOMŒ'OS, (α, non, and μοιος, like). DISSIMILAR or heterogene. Hippocrates uses this word for viscid or unnatural humours.

ANOMPHALOS, (from α, neg. and ομφαλος, a navel). Without a navel.

ANO'NIS, (from α, priv. and ονημι, to assist,) so called, because it hinders the plough; called also *ononis*, *resta*, or *aresta bovis*, *remora aratri*, PETTY-WHIN, CAM-MOCK, and REST HARROW. *Ononis spinosa* of Linnæus, Sp. Pl. 1006.

The cortical parts of the roots have a faint smell, and a sweetish bitter taste. In a dose of ℥ i. they are diuretic and aperient.

ANO'NYMOS, (from α, neg. and ονομα, a name). NAMELESS.

It was formerly a name of the cricoid cartilage; and many exotic trees and shrubs are ranked now under this name.

ANO'NYMOS AMERICA'NA. A sort of wild madder. See RUBIA SYLVATICA LEVIS.

A'NORA. See OVORUM TESTÆ et CALX.

ANO'RHIDES, (from α, neg. and ρηις, a testicle). Such as are born without testicles.

ANORE'XIA, ANOREXY, (from α, neg. and ορεξις, appetite): also *aphositia*, *asitia*. A WANT OF APPE-TITE, WITHOUT LOATHING OF FOOD. The Greeks call such as take no food, or have no appetite, *anorecti* and *asiti*; but those who have an aversion to food, they call *aphositoi*.

This disorder, when original, is caused by bad diet, and excess in eating or drinking. In old age it may proceed from weakness. But it is more frequently a symptom of some other disorder, particularly of fevers, and the cure depends on the removal of the original one. Dr. Cullen ranks this genus of disease in the

class *locales*, and order *dysorexia*. He seems to think it always symptomatic; yet points out two species, viz.

1. *ANOREXIA HUMORALIS*, when the stomach is offended with mucous, bilious, or other humours.

2. *ANOREXIA ATONICA*, when the fibres of the stomach have lost their tone. He uses this word *anorexia* as synonymous with *dyspepsia*.

In the first species an emetic is highly necessary, and must be occasionally repeated, lengthening if possible the intervals; and during the interval, warm tonics and aromatics should be employed. From the emetics a large quantity of very viscid mucus is sometimes thrown up; and it has been an object to dissolve this substance, but no solvent has yet been found. We have tried lime water, pure kali, and ammonia, with little success. It must be occasionally discharged, and its accumulation prevented by aromatics and tonics. The whole tribe of astringents and stomachics have been employed, but scarcely any one merits a preference. Bile in the stomach produces anorexia and nausea, with a putrid taste, sensible on the back part of the tongue: this also must be discharged; but it may be corrected with lemon juice, though, in weak stomachs, a considerable commotion follows.

If excess in drinking is the cause, besides temperance and a light but cordial nourishing diet, with daily exercise, the dilute acid of vitriol with the bark, and, when circumstances admit, the waters of Bath, Buxton, Llandrindod, Pyrmont, and other chalybeates, will be serviceable.

If acids prevail in the *primæ viæ*, vegetables should be avoided, and the diet be chiefly of the animal kind. The drink may then be Seltzer water, or any of the chalybeate kind; magnesia, warmed with the oil of carui, is useful; or any of the warmer bitters with the pure kali.

If there are a nausea and aversion to food, the same remedies in general succeed as in a simple loss of appetite; the difference of the cases consisting only in the degree. Hoffman particularly commends mint and its preparations. See *APEPSIA*.

*ANO'SIA*, (from  $\alpha$ , neg. and  $\nu\sigma\sigma\iota\varsigma$ , a disease). The absence of a disease.

*ANO'SMIA*, ( $\alpha$ , non. and  $\sigma\sigma\eta$ , odour). A diminution or loss of smelling. This function may be destroyed in various ways, from a dryness of the pituitary membrane; its too great mucosity, as in a coryza; its infarction, as in ozæna; and from an obstruction of the nostrils, as in a polypus. According to Dr. Cullen the species may be reduced to,

1. *ANO'SMIA ORGANICA*, when there is some evident fault in the membrane that lines the nostrils, as a catarrh, a polypus, a venereal infection, &c.

2. *ANO'SMIA ATONICA*, when the membrane of the nostrils has no perceptible imperfection, as in paralysis. In these different instances, an attention to the cause will lead to the means for relief.

*ANOTA'SIER*. See *AMMONIACUS SAL*.

*ANO'THEN*. See *ANO*.

*A'NPATER*. See *SULPHUR*.

*A'NSER*. (Syriac word, *AUZA*.) The goose. See *ALIMENT*.

The fat of geese is penetrating and discutient beyond that of any other animal.

*A'NSJUDEN*. See *ASALETIDA*.

*ANTA'CIDA*, (from  $\alpha\nu\tau\iota$ , against, and *acida*, acids). *ANTACIDS*. Such remedies as resist or destroy acids. See *ALTERANTS*.

The best antacid is pure kali; but it is not sufficient that we destroy the present acidity in the stomach: its digestive power must be increased in such a degree as to prevent future disturbance from this cause; for which purpose, see *ANOREXIA*, and *APEPSIA*.

*ANTAGONISTA*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\gamma\omega\nu\zeta\omega$ , to strive). One acting in opposition to another.

This word is applied to muscles which counteract each other.

*ANTA'LE*. See *ANTALIMUM*.

*ANTA'LGICUS*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\lambda\gamma\sigma$ , pain). Such remedies as ease pain.

*ANTALIMUM*, (from  $\alpha\nu\tau\alpha$ , before, and  $\alpha\lambda\varsigma$ , the sea,) also called *antale*, and *tubulus marinus*. It is a shell like a pipe, of the thickness of a small quill, and about an inch and a half in length; it is hollow, and hath hollow lines running from one end to the other: its colour is white, or a greenish white. A kind of worm is the natural inhabitant of this shell, and its medical uses are the same with the shells of oysters, &c.

*ANTALKALINA*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\lambda\kappa\alpha\lambda\iota$ , alkali). Such medicines as resist or destroy acids. See *ALTERANTS* and *ANOREXIA*. Bile is the most common alkaline acrimony found in the stomach.

*ANTAPIRODISIACOS*, *ANTAPHRODITICA*, (from  $\alpha\nu\tau\iota$ , against, and  $\text{Αφροδιτη}$ , Venus). Anti-venereal, or such means as extinguish amorous desires. Such are violent fatigue, especially if combined with low diet, whatever draws the attention from venereal subjects, active stimulant diuretics, and sometimes, apparently, nitre and camphor.

*ANTAPODO'SIES*, (from  $\alpha\nu\tau\alpha\pi\omicron\delta\iota\delta\omega\mu\iota$  to reciprocate). Returns of the paroxysms of fevers.

*ANTARTHRETICUM*, *ANTI-ARTHRITICUM*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\rho\theta\rho\iota\tau\iota\varsigma$ , the gout). Medicines against the gout.

*ANTASTHMATICA*, *ANTI-ASTHMATIC*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\sigma\theta\mu\alpha$ , an asthma). Remedies against an asthma.

*ANTATRO'PHON*, (from  $\alpha\nu\tau\iota$ , against, and  $\alpha\tau\rho\phi\iota\alpha$ , a consumption). Medicines against consumptions.

*ANTECE'DENS CAUSA*, (from *antecedo*, to go before). See *PROEGUMENE*.

*ANTECEDE'NTIA SIGNA*, *ANTECEDENT SIGNS*. Such signs as precede the disease.

*ANTELA'BIA*, (*ante*, before, and *labium*, a lip). The extremities of the lips.

*ANTELIX*, or *ANTIHELIX*, (from  $\alpha\nu\tau\iota$ , opposite, and  $\eta\lambda\iota\zeta$ , the helix). It is that part of the ear which is opposite to the helix.

*ANTEMBALLO'MENOS*, *ANTIBALLO'MENNA*, (from  $\alpha\nu\tau\iota$ , instead of, and  $\epsilon\mu\beta\alpha\lambda\lambda\omega$ , to contribute). *SUBSTITUTED*. Called also *succedanea*, *succedaneous*.

*ANTEMBASIS*, (from  $\alpha\nu\tau\iota$ , mutually, and  $\alpha\mu\beta\alpha\iota\nu\omega$ , to enter). A mutual insertion or ingress, applied by Galen to the bones.

*ANTEMETICA*, (from  $\alpha\nu\tau\iota$ , against, and  $\epsilon\mu\epsilon\tau\iota\kappa\omicron\varsigma$ , vomiting). Remedies against vomiting. These are all neutral salts, particularly the citras potassæ (the saline draught); and its power in this respect is increased if

given in an effervescing state; opiates, and, in cases of debility, a glass of wine, or even brandy.

ANTENDE'IXIS, (from *αντι*, against, and *ανδεικνυμι*, to indicate). *Contra-indicatio*. A CONTRA-INDICATION. When one symptom requires a remedy which another symptom forbids. *Prohibens* is used in the same sense.

ANTENEA'SMUS, (from *αντι*, against, and *πεινασμος*, implacable,) ANTENEA'SINUM. The same with *enthusiasmus*. A particular kind of madness: in it the patient is furiously irritated, and endeavours to lay violent hands on himself. These people are apt to be seized with sudden convulsive startings of the hands and feet; and therefore the disease is thought to coincide with the *chorea sancti viti* in some degree.

ANTEPHIA'LTICS, (from *αντι*, against, and *εφελκτος*, the night-mare). A name for the remedies adapted to the cure of this disorder.

ANTEPILE'PTICA, (from *αντι*, against, and *επιληψις*, the epilepsy). See EPILEPSY.

A'NTERA. See ANTHERA.

ANTERIOR MALLEOLUS, (from *ante*, before, and *dim.* of *maltua*, a mallet). See MUSC. EXTERN. AURIS.

ANTERIO'RES NA'SI, Musc. See PYRAMIDALIS NASI.

A'NTERIT, MERCURY. See ARGENT. VIVUM.

ANTHEA, (from *ανθος*, a flower,) in the plural signifies REDNESS, like the top of a carbuncle.

ANTHE'LIX. See AURICULA and ANTELIX.

ANTHE'LMIA, (from *αντι*, against and *ελμινς*, a worm,) the annual WORM-GRASS of JAMAICA. *Spigelia anthelmia* Lin. Sp. Pl. 213. The perennial worm-grass of Maryland is the Indian pink. It is the *Spigelia Marylandica*, though formerly referred to the genus *lonicera*, with the trivial name of *Marylandica*.

It is found in different parts of Jamaica, and of the other windward islands.

Half a dram of this latter herb may be infused five or six hours in a quarter of a pint of boiling water; one half of the strained liquor may be given to a child of twelve years old, and the other half the next morning: if no inconvenience is manifest from this dose, the infusion may be made still stronger.

For adults who are not remarkably feeble,  $\frac{3}{4}$  iii. of this herb may be boiled in a pint and half of water to  $\frac{1}{2}$  i. and the doses may be from two to six common spoonfuls, according to its effects on the patient.

In most persons it procures sleep; in many, after taking a full dose, the eyes are observed to sparkle, and also to be distended after the sleep is over. If there was a fever from worms, the pulse becomes more regular, and the heat moderate; and, by the use of cathartics, worms are discharged. This medicine must be continued as long as the worms are observed to pass away with the stools. If its effect is such as to produce a painful distention of the eyes, it must be omitted. An emetic should generally precede its use: in large doses it sometimes proves emetic and cathartic, produces vertigo, dimness of sight, and convulsions of the eyes. It should therefore be cautiously administered, with the intervention of a purge of calomel and rhubarb. In general, however, in this climate it is very inert, probably from being too long kept.

ANTHELMINTICA, (from *αντι*, against, and *ελμινς*, a worm). *Vermifuges* and *antiscolica* are words of the same import.

These are medicines which either destroy or expel worms situated in any part of the primæ viæ. They were formerly divided into those which destroy, and those which expel worms: modern authors have formed four species, because there may be cases where the exhibition of either may be improper, as the particular state of the stomach and intestines may be unable to bear their action.

| 4. TONICA.      | { Worm-seed.<br>Tuscany infusion, and powder.                     |

This more complicated arrangement appears however, to be an unnecessary refinement. Were we to refine in turn, we should divide them into external and internal; referring to the latter the remedies for itch, the mode of extracting the vena medinensis, and animals, by puncture. At present, however, we must confine ourselves to the internal anthelmintics; and we find it only necessary to distinguish the medicines that destroy worms, into those that act mechanically, or those which poison.

Worms are most common in children, and more frequent in the human body than in animals. We remarked, in treating of animals, that all nature swarmed with life, and that a nidus was only requisite to produce, in each instance, species peculiarly its own. Mucus is much more prevalent in the bowels of children, for reasons that cannot be assigned, than in those of adults, and worms are consequently more often found; nor are the proofs of the abundance of mucus equivocal, for children bear the most active laxatives with ease: they bear doses of cathartics which to strong adults would be highly dangerous. This, then, is the reason why children are so often infested with worms; and this, too, is the reason why worms are so often unjustly accused of producing their complaints. No medicine is half so fatal to worms as fever; for fever, excited by surgical operations, where the general system was not previously affected, will generally occasion worms to be discharged. It is certain, indeed, that in relaxed habits, mucus of the intestines is more particularly copious, and consequently tonics occasionally prove anthelmintics; but they act so remotely that they do not deserve this title, nor would they have obtained it but that some of the narcotic bitters are, at the same time, bitter and poisonous to these animals. This is particularly observable in the tansy, the fetid hellebore, and the fern roots.

The mechanical anthelmintics are, the powder and filings of tin, the setæ of the *dolichos pruriens*, amalgams of tin and quicksilver, crude quicksilver, and aurum musivum. Numerous are the nauseous fetids employed to kill worms; and from the inefficacy of the greater number, we suspect that they have been sup-

posed equally disagreeable to worms and our own palates. Among the more noted anthelmintics, is the cabbage tree bark (*Geoffrea inermis*); savine; rue; worm seed (*artemesia santonica*); male fern root; southernwood; tobacco; the husk and extract of walnuts; the root of the yellow helmet flower (*aconitum anthora*); lavender cotton (*abrotanum femina*); bastard ipecacuanha (*asclepias curassavica*); several species of annona and jatropa; the pride of India bark (*melia azedarach*); helleboraster (*helleboris fetidus*), &c. Each of these medicines has had its advocates and opponents, and it is at last acknowledged, that few remedies of this class can be depended on. The last, however, the bearsfoot, is often effectual; and, in the tænia, the male fern root is almost certain. That it acts as a poison there is great reason to believe, since the portions discharged, that before the exhibition of the medicine had life, are afterwards voided dead. The tobacco is chiefly anthelmintic in clysters, in cases of ascarides; and, when these worms abound, the asafœtida has in the same way succeeded. Other remedies seem to act as poisons in a different manner. Olive and castor oil certainly destroy worms. Even the lower classes of animals require air, and, though they are enabled to extract oxygen more perfectly from impure air, and to live longer without that which is pure, yet they require it to be renewed. Oils may deprive worms of their natural food, or may obstruct those pores through which they may receive supplies either of air or nourishment. Alkaline and earthy neutrals are of uncertain action. Salt and water perhaps evacuate only; but in the muriat of barytes we may suspect a poisonous quality. Sulphurated gas, or waters impregnated with sulphurated hydrogen gas, have been recommended to impregnate the fluids so as to destroy hydatids. The Harrowgate water possesses similar impregnations, and may be equally useful; but we have never employed it, or heard from adequate authority of its success. Mercurials, except as evacuates, are of doubtful efficacy; but the corrosive sublimate has been recommended in tænia.

The choice of anthelmintics for different kinds of worms, is a subject that requires some attention. In the lumbrici, all the poisonous bitters are preferable; but the fetid hellebore is the most certain and effectual. The best mode of exhibiting it is in powder. It is an evergreen, but has each year, as usual, new leaves. An equal number of the new and old are carefully dried and powdered; and from two to six grains of the powder may be given, according to the age or constitution, twice a day, interposing an active laxative about twice a week. In tænia, the male fern root, salt water, sulphat of barytes, and the mechanical anthelmintics, except the setæ of the dolichos, which is rather adapted to the lumbrici, are chiefly useful. The raspings of a pewter plate with a rough file we have found the best form of powdered tin; but the male fern, followed by the drastic powers of calomel and gamboge, according to the receipt of Madame Bouffler, seldom fails. In ascarides we must depend chiefly on those medicines which act only when they arrive at the rectum, or those whose action is very powerful, viz. aloes and calomel. Infusions of tobacco, solutions of asafœtida, and of olive oil, injected into the rectum, are very effectual: but these animals are seldom eradicated. We have observed

that they are generally accompanied with pain and affections of the stomach, and have doubted whether, though they appear exclusively in the rectum, their origin is not in the superior part of the canal. If this be true, tonics should probably be combined.

The choice of these medicines, as adapted to particular constitutions, furnishes little subject of remark. In general the more active drastics should be avoided in the weaker habits; and we have suspected that some of the poisonous anthelmintics are not exhibited without danger. The muriat of barytes and the male fern root have, we think, been sometimes injurious. The fetid hellebore, though apparently the most suspicious medicine, from frequent trials we can pronounce free from any effects inimical to the general health.

ANTHE'MIS, (from *ανθος*, a flower). WILD CAMOMILE. See CHAMEMELUM VULGARE.

ANTHE'MIS COTULA and NOBILIS. See CHAMEMELUM FETIDA, and FLORE PLENO.

ANTHE'MIS PYRETHRUM. See PYRETHRUM. Galen says the anthemis is the same as *euanthemon*.

A'N'THERA, (from *ανθος*, a flower). Also *antera*. A compound medicine used by the ancients, called from its florid red colour. Various compositions had this name. *Antheræ*, indeed, were prepared for any particular part of the body, in the form of powders, or electuaries, and were used as collyriums, dentifrices, &c.

ANTHE'REA. See ANTHORA.

ANTHE'REON, (from *ανθος*, a flower). Called also *Geneion*. Hippocrates uses this word to express the chin, and all that part of the face where the beard grows.

ANTHE'RICOS, (from the same). According to Dioscorides, it is the flower of the asphodel; others say it is the stalk only. See ASPHODELUS.

ANTHE'RICUM. See ASPHODELUS LUTEUS.

A'N'THINES, (from *ανθος*, a flower). A name of some medicated oils and wines, named from their red colour.

ANTHOPHY'LLUS, (from *ανθος*, a flower, and *φυλλον*, a leaf). The AROMATIC CLOVE, when ripe. See CARYOPHILLI AROMATICI.

ANTHORA, ANTITHORA, (from *αντι*, against, and *θορα*, monk's-hood,) so called because it is said to counteract the effects of the thora. *Antherea*, *aconitum salutariferum*, WHOLESOME and YELLOW HELMET FLOWER, WHOLESOME WOLF'S BANE, MONK'S HOOD, *aconitum anthoræ* Lin. Sp. Pl. 751.

This plant is distinguished from the poisonous aconites, by the leaves not being glossy, by their being cut entirely down to the foot stalk, and by the segments being very narrow, and of nearly the same width from end to end. It is a native of the Alps and Pyrenées, from whence we have the dried roots, which are of an irregular roundish shape, a little oblong, brown on the outside, white within, hard to break, but not tough; to the taste it is acrid and bitter, to the smell it is faint; if chewed, it a little constringes the fauces, and a nauseous sweetness is perceived. In doses of ʒi. it is cathartic and anthelmintic.

ANTHOS, *ανθος*, (from *ανα*, upwards, and *θω*, to run, because in its growth it runs upwards,) a FLOWER. Hippocrates means by this word, flowers in general; and if Galen is right in his comment, includes the seeds

with the *flowers*. It is also used for *æris flos*; but when used alone, signifies the flowers of rosemary, and is sometimes, but improperly, taken for the plant. See *ÆRIS FLOS*, and *RORISMARINUS*.

**ANTHO'SMIAS**, (from *άνθος*, a flower, and *οσμή*, smell). A name applied to sweet scented wine.

**A'NTHOUS**, (from *άνθος*, a flower). Properly rosemary; but, transferred to metals, it signifies the fifth essence, or elixir of gold.

**ANTHRA'CIA**, **ANTHRACOSIA**, (from *άνθραξ*, or *A'NTHRAX*). A BURNING COAL. A hard, painful, burning swelling, which attends the plague. See **CARBUNCULUS**.

**ANTHRACO'SIS O'CULI**, *άνθραξ*. A scaly corrosive ulcer of the eye, attended with a defluxion.

**A'NTHRAX**. See **CINNABARIS**, and **CARBUNCULUS**.

**ANTHRI'SCUS**, (from *άνθρισκεα*, flowers). See **CAUCALIS**.

**ANTHROPE'A**, (from *άνθρωπος*, a man). See **CUTIS**.

**ANTHROPOLO'GIA**, (from *άνθρωπος*, a man, and *λογος*, a discourse). The science of anatomy.

**ANTHROPOMO'RPHOS**, (from *άνθρωπος*, a man, and *μορφη*, shape). See **MANDRAGORA**.

**ANTHROPOSO'PHIA**, (from *άνθρωπος*, a man, and *σοφία*, wisdom or knowledge). The knowledge of the nature of man.

**A'NTHUMON**, among the ancient physicians, the name of the epithymon or dodder growing on thyme.

**ANTHYPNO'TICA**, (from *αντι*, against, and *υπνος*, sleep). Medicines against sleepiness. These have been usually the correctors of opium; among the chief of which, vinegar, without sufficient reason, has been accounted. Coffee is certainly, in many constitutions, a preventer of sleep; and tea also in a less number. Many others do not occur in the lists of the materia medica; and we need scarcely add the well known observations of attention long fixed on abstract sciences, or agreeably amused by interesting details, indolence, inactivity, or a mind harassed by anxiety and apprehension, as means of preventing sleep.

**ANTHYPOCHONDRI'ACA**, (from *αντι*, against, and *υποχονδρια*, the hypochondria). Medicines against the disorders of the hypochondria.

**ANTHYPOCHONDRI'ACUM**, **ANTHYSTERICUM**, **SAL**. It is the residuum remaining after the distillation of the water, and sublimation of the sal ammon. which consists of the marine acid and the fixed alkaline salt, or the alkaline earth, according as one or the other was used in the process. The same term is applied to this salt when refined.

**ANTHYSTERICA**, (from *αντι*, against, and *υστερα*, the uterus). Medicines against hysteric affections.

**ANTI**, (*αντι*, contra, against). This Greek preposition is generally used in a compound term. See the preceding articles.

**ANTI'ADES**. See **TONSIL**. It sometimes signifies the tonsils, when inflamed. From *αντιαιω*, to be opposite; because they answer one another.

**ANTIA'GRI**, (from *αντιαιδες*, the tonsils, and *αγρευ*, a prey). Tumours of the tonsils.

**ANTIBALLO'MENA**. See **ANTEBALLOMENOS**.

**ANTICACHE'CTICA**, (from *αντι*, against, and *καχεξια*, a cachexy). Medicines against a cachexy.

**ANTICA'DMIA**. A third kind of fossil cadmia, also called *pseudocadmia*. *Anti* is here joined to express its being substituted for the true cadmia.

**A'NTICAR**. See **BORAX**.

**ANTICA'RDIIUM**. The hollow at the bottom of the breast. (From *αντι*, against, and *καρδια*, the upper orifice and the pit of the stomach). Called also *scrobiculus cordis*.

**ANTICATARRHA'LIS**, (from *αντι*, against, and *καταρρος*, a catarrh). A remedy against a catarrh. See **CATARRH**.

**ANTICAUSO'TICUS**, (from *αντι*, against, and *καυσος*, a burning fever). Remedies against burning fevers.

**A'NTICHEIR**, (from *αντι*, against, and *χειρ*, the hand). The thumb of a person's hand. See **POLLEX**.

**ANTI'CIPANS**, (from *anticipo*, to anticipate). The Greeks express this by *πιοληπτικός*: it is applied to diseases, each of whose fits begins somewhat sooner than the preceding. If the catamenia arrive before their ordinary period, they are said to anticipate.

**ANTICNE'MION**, (from *αντι*, over-against, and *κνημη*, the calf of the leg). Hippocrates uses this word to express that part of the tibia which is bare of flesh.

**ANTICO'LICA**, (from *αντι*, against, and *κολικη*, the colic). Remedies against the colic. See **COLIC**.

**ANTICONTO'SIS**, (from *αντι*, against, and *χοντος*, a staff or pole). In Hippocrates it signifies the supporting a person with a staff or crutch.

**ANTICUS**, before applied to the situation of different muscles, and used as an epithet.

**ANTIDI'NICA**, (from *αντι*, against, and *δινος*, circumgyration). Medicines against a vertigo. See **VERTIGO**.

**ANTIDOTA'RIIUM**, (from *αντιδοτος*, an antidote). See **DISPENSATORIUM**.

**ANTIDO'TOS EX DUO'BUS CENTAU'RÆ GENE'RIBUS**. See **CHAMEDRYS**.

**ANTIDO'TUS**, or **ANTIDOTUM**. The Chaldee word for which is *beluzaar*, also called *alexicaea*. An antidote, (from *αντι*, against, and *διδωμι*, to give). See **ALEXIPHARMICA**, and **ADAMUS**. Sometimes it is a general name for medicines; occasionally for compound ones.

**ANTIDYSENTE'ERICA**, (from *αντι*, against, and *δυσεντερια*, a flux). Medicines against a dysentery. See **DYSENTERY**.

**ANTIFEBRI'LE**, (from *αντι*, against, and *febris*, a fever). Remedies against a fever. See **FEVER**.

**ANTI'GONI COLLY'RIIUM NI'GRUM**. The black collyrium of Antigonus. It is made of cadmia, antimony, pepper, verdigrise, gum arabic, and rain water.

**ANTIHE'CTICA**, (from *αντι*, against, and *επτικός*, a hectic fever). Remedies against a hectic fever.

**ANTIHE'CTICUM POTE'RII**. A medicine invented by Poterius, also named *antimonium diaphoreticum Joviale*; formerly extolled as effectual in hectic fevers; but from long experience disregarded, as of no consequence. It is an oxide of tin, and chalybeated regulus of antimony, in consequence of their deflagration with nitre. The neutral salt is separated by wash-

ing. For its mode of preparation, see Lewis's Dispensatory Improved. Ed. 8vo. Edinb. 1786.

ANTIHE'LIX. See AURICULA and ANTELIX.

ANTI-ICTERIC SPIRIT, in pharmacy. As biliary calculi, out of the body, are dissolved by an union of spirit of turpentine and spirit of wine, the union of these fluids has been attempted by distillation. Half an ounce of spirit of turpentine has been distilled with half a pint of spirit of wine; and the fluid drawn off, separated from the uncombined oil. One other circumstance is necessary, viz. a method of injecting this spirit into the gall-bladder!!

ANTILE'PSIS, (from *αντιλαμβάνω*, to lay hold of). Hippocrates applies this term to the method of securing bandages from slipping. *Αππρεχενσιο* and *αππρεχενσοριυμ* are used in the same sense.

ANTILO'BIUM, (from *αντι*, against, and *λοβος*, the bottom of the ear). See AURICULA.

ANTILOI'MICA, (from *αντι*, against, and *λοιμος*, the plague). Remedies against the plague.

ANTILOPUS. Called also *gazella Africana*, *capra-strepsiceros*, *strepsiceros*, the ANTELOPE.

It is of the genus *cervus*. The hoofs and horns have been used in medicines against hysterics and epilepsy; but are now neglected.

ANTILY'SSUS, (from *αντι*, against, and *λυσσα*, the madness caused by a bite of a mad dog).

It is the name of any medicine for the cure of this sort of madness. The pulvis antilyssus is composed of equal parts of the lichen cinereus terrestris and pepper. Hill's medicine is composed of 3 ss. of alum, 3 ss. of chalk, 3 iij. of bole armoniac, 3 i. of root of helenium, and six drops of oil of aniseed.

ANTIMO'NIALES PI'LULÆ. Dr. Ward. WARD'S ANTIMONIAL PILL. Pills consisting of well levigated glass of antimony: one pill, containing about a grain of the antimony, is a full dose.

Mr. Clutton, the chemist, says that they contain a portion of arsenic.

ANTIMO'NIALIS PU'LVIS. The ANTIMONIAL POWDER.

Take of antimony coarsely powdered, hartshorn shavings, of each two pounds; mix and put them into a broad red-hot iron pot, stirring constantly till the mass acquires a grey colour. Powder the matter when cold, and put it into a coated crucible; lute it to another crucible inverted, which has a small hole in the bottom; augment the fire by degrees to redness, and keep it so for two hours; lastly, reduce the matter, when cold, to a very fine powder: this is said to be a preparation similar to, and equally efficacious with, that of Dr. James. It is inserted in the new Pharmacopœia, and is certainly preferable to the tartarized antimony joined with the testaceous powder which used to be substituted for that of James. This powder is a calx, intimately blended with the residuum or absorbent earth of the hartshorn. It is, however, unequal in its effects, probably from the degree of heat; and is more apt to affect the bowels than the James' powder. From three to six grains are a dose; if joined with a quarter of a grain of opium, it acts as a diaphoretic, and is considered as alterative. In inflammatory fever of the rheumatic kind, by repeating the dose every six or eight hours, it has frequently proved beneficial.

ANTIMO'NIUM, ANTIMONY. Called also *stibium*,

*alcimad*, *alcotol*, *stimmi*, *platyophthalmion*, *larbason*, *satanus devorans*, *lufus philosophorum*, *aurum leporosum*, *ens primum solare*, *alamad*, *madail*, *duenech*, *afrob*, *alcofolo*, *cosmet*, *calmet*, *gynæcium*.

Antimony is sometimes found in a particular ore, but most frequently mixed with other metals. Basil Valentine, a German monk, gave it, as tradition relates, to some hogs, which, after purging, it greatly fattened; thinking in like manner to feed his brother monks, all died by the experiment; hence the name ANTIMONY, ANTI-MONK, (*αντι*, against and *μονος*, monk). It is called *satanus devorans*, and *lufus philosophorum*, from its power of devouring or destroying, as it were, all metals, when in fusion with it. It is a semi-metal, of a whitish or silver colour.

Mines of antimony occur in Hungary, Transylvania, Germany, France, and in England. The French *antimony* contains about equal parts of regulus and sulphur; but the best is from Hungary. The English is often mixed with lead or tin, from which it must be separated: that which is spotted with red is supposed by Dr. Alston to contain some arsenic, and should be rejected.

The antimony is generally found mixed with hard stones or spar, from which it is separated by eliquation. Some ores are mixed with arsenic or with cobalt; some are dug up composed of fine shining lines like needles, sometimes disposed in regular ranks, at others without any observable order; this is termed *male antimony*;—some are disposed in thin broad plates or laminæ, and called *female antimony* by Pliny; and, from their different mixtures and appearances, other names are given to them. See TRAITE' DE MINERALOGIE DE HAUY, iv. 252.

The mineral, broken into pieces, is put into earthen pots, whose bottoms are perforated with small holes, and a moderate fire is applied round them; as the *antimony* melts, it runs through the holes in the bottom of the pots, and is received into inverted conical moulds that are placed underneath; in these moulds the lighter scoriæ rise to the surface, while the purer and more ponderous metal falls to the bottom; the broad part of the loaves is consequently less pure than the smaller end. The *antimony* thus separated from its ore is called crude, and is a combination of the metal with sulphur.

The goodness of crude *antimony* is discovered by its weight, from the loaves not being spongy, from the largeness of the striæ, and from its totally evaporating on a strong fire.

Its general appearance is that of a ponderous brittle mineral, or semi-metal, composed of long shining streaks like needles, mixed with a dark leaden coloured substance. It hath no particular taste or smell, and is brought to the shops in the form of conical loaves. Its specific gravity is 6.860, and it melts at 779° of Fahrenheit.

*Antimony*, like most of the best medicines, found its way as an internal one in the medical practice with great difficulty; the ancients, if their *stimmi* was really antimony, considered it as a poison, and only fit for external uses. Basil Valentine, in the seventeenth century, 1676, first brought it into credit as an internal medicine, publishing a work called *Curus triumphalis Antimonii*; but it soon lost its repute, until Paracelsus raised its character again, after which it

was received and rejected several times, until, by the labours of Crato of Kraftsheim, Lintilius, Le Febvre, and, above all, Hoffman, it acquired an established place in regular practice; and is now justly ranked with the most valuable part of the *materia medica*.

In the state of crude antimony, notwithstanding its boasted efficacy in rheumatic, cancerous, and other cases, it appears, from repeated trials, to be an inert substance with regard to the human body: it is, however, ordered by some physicians to be taken from one scruple to a dram, two or three times a day, in cutaneous and leprous disorders, in its levigated state. Its preparations are, in general, used both as alteratives and evacuates, and hardly any article in the *materia medica* will admit of so extensive a use in acute and chronic diseases. In fevers of the inflammatory kind, and inflammations, antimonials are alike the proper remedy; and in chronic diseases they may be often depended on. They promote all the secretions and excretions, particularly those of the skin, intestines, urinary passages, and bronchial glands, by gently irritating the whole vascular system. If given in small doses, gradually increased, yet in the proportion which excites no sensible discharge, they are highly efficacious.

As auxiliary to other medicines on which the cure more directly depends, their efficacy is considerable. They quicken their action and increase their powers, particularly those by which any evacuation is to be promoted; with such medicines, their operation is also more easy: as an expectorant, some of its preparations excel; but the discharge from the bronchial glands has been mistaken for a salivary excretion.

The preparations of this drug are numerous, and vary in their strength according to the quantity of nitre employed in the deflagration, or the discharge of the sulphur; but, except that which is called the muriated antimony, they only differ from each other in their degrees of activity. Two private prescriptions, which are deservedly celebrated, may be also mentioned, viz. the febrifuge powder of Dr. James, and that of Edinburgh; the latter of which is recommended to us on the best authority, as possessed of those very desiderata, the want of which was the cause of other preparations being complained of. It is called *antimonial salt*, and seems to be a preparation similar to that of tartarized antimony, though kept a secret by those who prepare it. It is soluble in water—invariably of the same strength—and a grain or two under or over the dose is not attended with any inconveniences. It is probably prepared with the *mercurius vitæ*, instead of *antimonium vitrificatum*; thus forming an *antimonium tartarizatum*. See TARTAR EMETICUM.

The labours of the alchemist have tortured antimony in various ways, as it was one of the metals by which he hoped to gain his imaginary riches. The pharmacist has not been less diligent at a later era; but our account of its chemical properties must chiefly or entirely respect its medicinal use.

Antimony, in its crude state, is combined with sulphur; and, as a medicine, we have said, nearly inert. When completely oxidated, as in the former preparation of the diaphoretic antimony, it is equally useless. Its active form is that in which the sulphur is partly separated, or where the metal is combined with an acid. As every scientific examination of the comparative activity

of the different saline preparations shows that their effects are nearly in the proportion of their solubility, it is probable that the different calces also are active only as they are soluble in the fluids, perhaps the acid of the stomach. All the oxides are in different degrees soluble, and all are volatile. The carbonic acid alone has never formed an union with antimony.

The sulphur of the antimony is usually separated by deflagrating it with nitre or crude tartar, and the oxide is more or less active as the proportion of these additions is less or greater. The different preparations are generally denominated from the proportion of hydrogenated sulphuret, mixed with the metal. An alkali added to crude antimony forms a sulphuret, which dissolves the metal, and is called *liver of antimony*. If equal parts of crude antimony and nitre be deflagrated, a different combination of the metal, its alkali, and sulphur, are obtained, styled *saffron of antimony*. If sulphur of antimony, with three parts of nitre, be deflagrated, the metallic mass, mixed with the salts, is called the *solvent of Routhou*. When washed, it is the inert calx, mentioned under the appellation of *diaphoretic antimony*. The water employed in washing it, holds a little of the antimony, which, when separated by an acid, is called *cerussa antimonii*, or the *materia perlata of Kerkringius*. When some of the sulphur remains, by diminishing the proportion of nitre or tartar, the preparation is called the *medicinal regulus of antimony*. The metal and its oxides are equally volatile, and sublime in flowers, styled *nix antimonii*, which as a medicine is useless and neglected. Antimony exposed to great heat, excluding the air, becomes a glass, and the more readily the less it has been previously calcined. The regulus itself has been cast into pills, and in the form of cups. The pills are styled *perpetual*; for they produce a cathartic effect, and may be repeatedly employed without diminution: the cup imparts an emetic power to wine, without any loss of its substance or virtue by the employment of many years. Each is, however, uncertain, and often violent in its operations; and physicians have neglected both.

The vitriolic acid, if strong and hot, acts violently on antimony, and reduces it to a white inert oxide; the fluid above containing a solution of sulphat of antimony. The nitrous acid does not dissolve the metal, but is itself in part decomposed by it. We find a white oxide at the bottom, and a nitrat of antimony above. Water precipitates a part of the nitrat, but the remaining oxide is separated by an alkali, and becomes a deliquescent salt.

The muriatic acid scarcely acts on the antimony; but if the latter is oxidated by the nitrous acid, the solution is copious. The muriat of antimony is decomposed also by an alkali. The usual way, however, of combining antimony with the muriatic acid is, by oxidating the metal, or the acid, by a highly oxidated metallic salt, the corrosive sublimate. The metal thus united to the muriatic acid is highly soluble in water, and extremely corrosive. It sublimes in an oily form, and is called *butter of antimony*. It is called *antimonial caustic*, and in the late Pharmacopœias, *antimonium muriatum*. When a large proportion of water is added, the oxide, containing a small portion of the acid, is precipitated, called, from an Italian physician, the *powder of Algarotti*; by some, *mercurius vitæ*, though it

does not contain the smallest portion of mercury. The vegetable acids act on the metal more readily when oxidated; but this subject must be afterwards considered.

We are now enabled to examine the different preparations of antimony, and shall follow Dr. Black's arrangement. He considers the preparations of antimony retaining a portion of its sulphur, for of the pure regulus we shall take little further notice, as produced by simple triture; by the effects of heat and fire; by alkalis, nitre, and acids.

By triture alone, the *prepared antimony* of the shops is obtained. It is almost an inert mass; but we find Kunkell and some other authors recommending it in rheumatism; and we recollect its being used in the drastic electuary of Dover for dropsies, and as an anthelmintic. It forms the tablettes of Kunkell; and certainly sometimes produces nausea, when suspended in a bag, in the preparation of the Lisbon diet drink, in which the prepared antimony should be always employed.

By the effects of heat and fire we obtain the *vitrum antimonii*, the *antimonium vitrificatum* Phar. Lond. The sulphur is in a great measure separated by gentle heat; but the operation is difficult, from the volatility of the metal. It has been advised to add common salt of charcoal dust to diminish the fluidity and prevent sublimation; but the salt is sometimes decomposed, and renders the medicine dangerously active. The proper state of the oxide is that of a grey or ash colour, forming the darkish brown oxide of Thenard; whose valuable experiments on antimony communicated to the National Institute, but of which an abstract only, by M. Morveau, has been published (*Annales de Chimie*, xxxii. 257), we shall often refer to. In this state it contains 0.16 of oxygen; but in the glass, eight parts of the oxide of antimony are combined with one of the prepared antimony. The *vitrum antimonii* is a more important preparation, since it has been chosen for the antimonial oxide, from which the emetic tartar is usually prepared. This has always seemed to us one of the most certain states in which the oxide of antimony can be obtained, since a determined proportion of sulphur is necessary to its vitrification; and M. Vauquelin seems to be of the same opinion if the silicious earth which it acquires from the crucible, or from some parts of the remaining matrix, be separated.

The violent action of the glass of antimony is supposed to be mitigated by combining it with wax in the *vitrum antimonii ceratum*. This form, first recommended in the Edinburgh Medical Essays as a remedy for dysentery, is now neglected; since we gain nothing but what is more securely effected by other preparations of antimony. Eight parts of the glass are mixed with one of wax, and roasted over a gentle fire for a quarter of an hour. The wax seems to be in a great degree decomposed, for about one-ninth of the whole weight is lost.

An oxide of antimony with phosphat of lime occurs in the *pulvis antimonialis* of the London Dispensatory, the *pulvis stibialis* of the Dublin, and the *oxidum antimonii cum phosphate calcis* of the Edinburgh. It is introduced as a substitute for *Dr. James' powder*, and is certainly similar in its nature and effects. See ANTIMONIALIS PULVIS.

VOL. I.

The preparation we have there described is very near to the specification of Dr. James; yet, at the time of its introduction, physicians confidently believed that a portion of calomel was secretly added. It unfortunately happens that we seldom find this preparation exactly the same in two different processes, from some uncertainty probably in the heat which we cannot detect; and it certainly is more disposed to act on the stomach and intestines, and less on the skin, than the powder of Dr. James. It differs also from this powder, in leaving almost double of an insoluble residuum. The preparation itself is truly an oxide, and contains no portion of phosphoric acid; and this oxide is combined with the phosphat of lime, though not very intimately: whether this earthy salt involves the more acrid oxide, like the wax, or what other effect it produces, we are yet ignorant, but the preparation is truly valuable. In water it is wholly insoluble; but it may be suspended in a mucilaginous draught, and given advantageously in that form, with a little care, to avoid deposition. With a small proportion of opium, it has been already observed, we obtain very exactly the effects of James's powder.

M. Chenevix has recommended a preparation of this nature, apparently more certain in its effects. Equal weights of muriat of antimony and phosphat of lime are dissolved in the smallest quantity of muriatic acid, and the solution poured gradually into water alkalisied with ammonia. Some trials have been made with this preparation, but not sufficiently numerous to enable us to appreciate its real merits. It is certainly much milder than the *pulvis antimonialis*; more so than the James' powder. See *Philos. Trans.* for 1801. p. 379.

The first medicine prepared by the action of *alkalis on antimony* that we shall mention is, the former *regulus antimonii medicinalis*, the mildest *hepar antimonii*. One part of fixed alkali, and five of crude antimony, are melted together, with some common salt to promote their fusion; the result is a dark reddish brown insipid powder, not soluble in water; now rejected from the British and Irish Dispensatories. If the proportions of alkali are increased, the substance becomes gradually more soluble; and when the proportion is two parts of alkali to one of antimony, the salt is even deliquescent. The combination of the alkali and sulphur in the antimony forms a *hepar*, so called from the colour; and we thus obtain the different celebrated *livers of antimony*.

The *sulphur stibiatum fuscum* of the Dublin Dispensatory, the *kermes mineral*, is the second degree of oxidation of antimony, according to Thenard. It is an hydrosulphurated oxide containing sulphur, and, like glass of antimony, contains 0.16 of oxygen. It does not greatly differ from the golden sulphur except in the proportion of oxygen, and contains 72.760 of brown oxide of antimony. The principle of the composition is now sufficiently obvious; and we may only add, that the proportion of alkali differs. It was formerly two parts to one: in the Dublin formula, the alkali is equal to the antimony. The oxide is precipitated, in consequence of the kermes mineral being only soluble in the sulphurated hydroguret of potash, at 212°. As this heat lessens, the hydrosulphuretted oxide separates. In the different pharmacopœias the proportions differ; and, with fresh additions of sulphur and alkali, the whole of

T

the antimony may be perhaps converted to kermes. Fourcroy has given a new, and perhaps improved, form in the humid way. He boils six parts of pure potash 'of commerce' in twenty parts of water, and, to the boiling solution, adds about the twentieth part of the weight of the alkali, of prepared antimony. After boiling seven or eight minutes, the solution is filtered while hot, and the kermes suffered to precipitate. Gren and Hermstadt vary the proportions; but these differences relate only to commercial savings.

The kermes mineral has been highly esteemed on the continent in pneumonia; and is, in reality, a valuable preparation, since it is not so liable to become cathartic, or excite vomiting, as the other preparations of antimony. In pneumonia it is certainly a medicine of peculiar utility; and we strongly suspect, that, in other febrile diseases, it would be more advantageous than even the pulvis antimonialis. Why is it not tried? The question may be retorted on ourselves, and we have no adequate excuse to offer.

The *sulphur auratum antimonii* is not very different; and if the kermes mineral is often exposed to the air, it acquires so much oxygen as not to be a superior medicine. It is of an orange colour, prepared nearly as the former, taking care only to check the deoxygenation a little sooner. It contains about 0.18 of oxygen: the orange oxide of antimony is, in this preparation, 68.3 in 100 parts. Four pounds of the aqua kali are diluted with three pounds of water, to which two pounds of prepared antimony are added. These are boiled for three hours, strained while warm, and the superfluous alkali precipitated by the sulphuric acid, which must be afterwards well washed. In the dry way, five parts of potash are melted, with two parts of prepared antimony, and three of sulphur. The whole must be quickly melted, cooled, powdered, and dissolved in water. The sulphur auratum is precipitated, as before, with diluted sulphuric acid. The principle of both preparations is the power of the hydrogenated sulphuret of potash to dissolve the orange oxide, which by the acid is precipitated. The whole must be at once precipitated; for if done gradually, as was formerly the custom, the first portions were chiefly sulphur, and the third only was preserved for use. M. Proust, in the fifty-fifth volume of the *Journal de Physique*, has paid some attention to this subject; but the details are too minutely chemical for our consideration. He seems to have fully shewn the principle formerly alluded to, that the oxides, both at their minimum and maximum, are incapable of any combination with sulphur. For this reason, the oxides in an active state are only combined with this body, and it is not improbable that the sulphur, in every instance, is useless, though it is certainly neither injurious nor inconvenient. This preparation is not often employed in medicine, though scarcely inferior to the kermes mineral. It was once fashionable.

By the action of nitre on antimony we obtain the *crocus antimonii*. This is a sulphurated oxide also, and obtained by deflagrating equal parts of nitre and antimony; to which, as we have said, the London and Dublin colleges add a small proportion of sea salt. This sulphurated oxide, like the preceding, contains, according to Thenard, about 10.18 of oxygen. In the shops the proportion of nitre is sometimes curtailed, and the

medicine is useless. In its best state, the crocus of antimony acts unequally and violently, and is only used in veterinary practice.

With a less proportion of nitre this preparation is called also *regulus antimonii medicinalis*, and it is sometimes styled *crocus metallorum*. Macquer and Lemery choose to call it *liver of antimony*. With a larger proportion of nitre, viz. two parts of the latter to one of the metal, a milder preparation is obtained, viz. the *emeticum mitius* of Boerhaave. With three parts of nitre we obtain the *antimonium diaphoreticum lotum* of Meuser, *antimonium calcinatum*, or the *antimonium diaphoreticum*, and the *calx antimonii nitrata* when unwashed. All these preparations are inert, and now little employed. The *antimonium ustum cum nitro* consists of antimony roasted to a calx, and then exposed for an hour to a red heat with nitre. The remainder wasedulcorated with water, and it was erroneously supposed to be the same with James' powder. As a substitute for it this preparation was inserted in some of the former editions of the Edinburgh Dispensatory.

With acids the most active preparations of antimony are obtained. With the vitriolic acid the Dispensatories of the united kingdoms have admitted no formula. A vitriolated antimony was employed by Dr. Klaunig of Breslaw, which Werthof used with advantage in fevers, and adds, that it proved emetic, cathartic, and diaphoretic. We have no reason, however, to think it superior in efficacy to the other preparations. The antimony is repeatedly distilled from the muriatic acid; and the sulphat, thus formed, is sublimed. The sublimed substance is then powdered, and alcohol burnt on it. Wilson's *antimonium catharticum* is supposed to be of the same nature.

With the nitric acid we have no antimonial preparation. The *bezoardicum minerale* is, indeed, prepared with nitrous acid from butter of antimony; but the acid is decomposed, and no traces of it remain. The result is still butter of antimony; though the metal is more oxygenated, and the preparation much milder.

The muriats of antimony are very important preparations. The *antimonium muriatum* of the London, the *murias antimonii* of the Edinburgh, and the *stibium muriatum causticum* of the Dublin Dispensatory, are prepared in the same way. The crocus antimonii, with an equal weight of sulphuric acid, is added to double the weight of muriat of soda: the salt and the oxide must be mixed, and the acid slowly added. The whole is then to be distilled in a sand bath, and the sublimed matter suffered to deliquesce in the air. The liquid part is the muriat, or butter, of antimony. In this case the sulphuric acid decomposes the sea salt, whose acid unites to the oxide. In Thenard's scale this preparation contains one-twentieth of oxygen. As the sulphur adhering to the crocus antimonii renders the operation dangerous, Gottling's process is preferable. To four ounces of glass of antimony and sixteen of sea salt, he adds twelve ounces of sulphuric acid, diluted with eight of water. The butter of antimony is drawn off in a retort. This preparation is chiefly used as a caustic; yet we have been informed that it has been employed in very small doses internally: we know not with what success. The powder of algarotti we have already mentioned as its precipitate; and the Dublin college has

introduced a *calx stibii preparata*, in which the oxide is precipitated by an alkali. This last preparation contains 0.20 of oxygen.

The *emetic tartar* is the next preparation that occurs, and it is one of such convenient exhibition and extensive use, that all the art of the pharmacist, all the resources of modern chemistry, have been exhausted in rendering it more steady in its operation, more perfect, and more useful in its administration. We learn from Dr. Fordyce, that we are indebted for this preparation to Dr. Cullen. If true, we cannot sufficiently admire the sagacity and judgment that prompted him in the choice, nor be sufficiently grateful for a present of such value. In children, in maniacs, and many cases where no medicine could be given, this may be disguised; in all cases where active antimonials are wanted, this preparation may be easily and successfully administered. In almost every febrile complaint it is highly useful; and joined in a small proportion to resinous purgatives, it mitigates their acrimony, and renders them useful in smaller doses. Its advantages, however, will often recur, and we need not anticipate them in this place. The chemical details must now engage our attention.

The tartar emetic is emphatically called in French *l'emetique*, in the new chemical nomenclature; it is called *antimonium tartarisatum* by the London college; *tartris antimonii* by the Edinburgh; and *tartarum stibiatum* by the Dublin. The first two employ the crocus antimonii, and add three parts of this to four parts of the crystals of tartar, and thirty-two parts of water. The last orders two ounces of the precipitated calx of antimony, with four ounces of crystals of tartar finely powdered, and five pounds of water. In fact, the antimonium tartarisatum is a triple salt; for the crystals of tartar contain potash, and this union is essential to the medicine. The London appellation hits this union very happily; while the Edinburgh college, resigning the advantage of trivial names, which are as useful in pharmacy as in botany, renders every title a definition. The different oxides of antimony have all had their patrons; but the crocus is not in general prepared with sufficient accuracy for this purpose. The precipitated oxide of the Dublin Pharmacopœia, the pulvis algarotti of pharmacutists, or the glass of antimony, may with more propriety be employed. It is only sufficient that the calx contain 0.20 of oxygen: we have before given some reasons for preferring the glass.

Like all the preparations of antimony, emetic tartar is active in proportion to its solubility; and the scale of solubility extends from three times its weight in boiling water, and fifteen at 60°, to forty and eighty in the same circumstances. In the former case the salt was peculiarly pure. Were we to follow every refinement adopted at different times by different chemists in preparing the emetic tartar, we might fill a volume. The quantity of water need not be more than will dissolve the tartrite of antimony when formed, and the time of boiling no longer than is necessary to the combination. Some time longer than that required for the solution of the crystals of tartar is requisite, though not a considerable period, or longer than a quarter of an hour. The excellence of the preparation consists in the size, the shape, and the length of the crystals with which the solubility of the salt is connected. The proper form of its crystals is that of triangular pyramids, or in

octoedrons more elongated than those of alum. In general they are too short, and, if carefully examined, have a portion of uncombined oxide adhering to them. The impediments to a proper and regular crystallization are, first, the silica, discovered by Vauquelin; and he tells us, that if the salt be evaporated to dryness, this is separated in an insoluble state: the salt may then be crystallized without further impediment from it. Another cause of imperfect crystallization is a portion of uncombined tartrite of potash. For this reason the Dublin college order the fluid to be filtered, and the remaining salts to be thrown away; but the end may be as well obtained by increasing the proportion of the oxide. Thénard very properly advises two crystallizations; and this, we think, should always be done. His object is to separate the tartrite of lime, which crystallizes in silky needles. According to this author, the emetic tartar consists of thirty-eight parts of oxide of antimony; thirty-four of tartarous acid; sixteen of potash; and twelve of water, including loss. We observe a German chemist, in Tromsdorf's Journal, directs the solution, previous to crystallization, to be exposed for fifteen days to a strong light, which seems only to facilitate the formation of the crystals.

The antimonial wines of the Dispensatories are now only solutions of tartarized antimony in wine, or in a small proportion of water added to wine. These forms are convenient for division, and require no comment. The antimonial wine of the former edition of the London Dispensatory was an unequal medicine, as the glass of antimony infused in wine could be only dissolved by its tartar, which, in different wines, is in unequal proportions. Oxalates and acetates of antimony have been prepared; but their medical qualities are little known, or, if known, do not apparently differ from those of emetic tartar. The fluoric and boracic acids act on the oxides of antimony; but they have not yet been noticed by the medical chemist.

The decomposition of the antimonial salts, particularly the tartrites, is not so easy as some chemists have supposed. From a superficial view it would appear that all acids and alkalis would occasion a separation of their component parts. Authors, however, who have been full in their cautions on this subject, have not reflected that the emetic tartar is a triple salt, and that a minute portion of acid will affect only the tartrite of potash, while the antimonial neutral will not be altered in its medical properties, though, in a chemical view, the salt is not the same. The mineral acids will, indeed, decompose the neutral and the metallic salt, and some alkalis will certainly affect the latter. This must be particularly attended to if the preparations of foreign pharmacopœias are employed, as in many of their tinctures an alkaline salt is added. In the decoctions of our pharmacopœias it was sometimes an ingredient; but, we believe, the decoction of bardana was the last instance, and it is now disused. The peculiar powers of the emetic tartar are greatly weakened by bitters, and particularly the bark. A modern author of credit, Tromsdorf, remarks, that a scruple of emetic tartar, with an ounce of Peruvian bark in decoction, is not usually emetic.

Here, perhaps, we might stop; but various preparations, and various titles of well known preparations, are to be found in authors, of which a medical dictionary

should give some account. We have compacted what is useful in a continued narrative, but shall now insert a table of the preparations of antimony, in which they are arranged from the nature of the product, for which we are indebted to Dr. Duncan; and then add some of the preparations of foreign authors, which have been at least highly commended, though not usually employed in these kingdoms, in the order of the table.

Antimony has been exhibited:

I. In its metallic state.

- a. Antimonium: regulus antimonii.
- b. Alloyed.
  1. With iron: regulus antimonii martialis.
  2. With tin: regulus antimonii jovialis.
  3. With tin and copper: regulus metallorum.
- c. Combined with sulphur.
  1. Sulphurerum antimon. Ed. Antimonium Lond. Stibium, Dublin.
  2. Regulus antimon. medicinalis (Maet.). Febrifugum Craanii.
- d. Combined with sulphuret of potash.—Hepar antimonii.

II. Oxidised.

- a. In a smaller degree.
  1. Calx antimonii per se cinis antimonii.
  2. Flores antimonii argentini.
  3. Pulvis algarotti.
  4. Vitrum antimonii—combined with wax, vitrum antimonii ceratum.
- b. Combined with a little sulphur, crocus antimonii: crocus metallorum.
- c. ————— sulphuretted hydrogen, sulphur auratum antimonii.
- d. ————— hydroguretted sulphur, kermes mineral.
- e. ————— muriatic acid, butyrum antimonii.
- f. ————— tartarous acid and potash, tartarus emeticus: dissolved in wine, vinum antimoniale.
- g. ————— phosphoric acid and phosphat of lime, James's powder.
- h. Oxidised in a greater degree, antimonium calcinatum, London.

In following this table we must first remark, that, besides the alloys of iron, tin, or tin and copper, we find a *regulus saturninus* in Stahl; *r. venereus* in Lemery; an alloy of the regulus martialis with copper in Stahl, under the fanciful name of *rete vulcani*; *regulus lunaris*, and *solaris*, in Lemery, viz. antimony united with silver and gold. The regulus metallorum is usually styled the *electrum majus*; the regulus jovialis, *electrum minus*. We need scarcely add, that all these preparations are useless.

The *febrifuge of Craanen* excited general attention on the continent; and it has particularly engaged the attention of Stahl, of Hoffman, of Dieterich, and Vogel. It was supposed to be a specific in intermittents; to be of service in gout, in dropsy, and malignant fevers. In the long list of its qualities, however, which we have carefully perused, we perceive nothing but what other antimonials will perform; and, if useful in low fevers, the advantage must have arisen from the bark with which it was sometimes joined. It was prepared in a variety of ways: and the great object seems to have

been its red colour, from which it was called *rubinus antimonii*, and *magnesia opalina*.

The *calx*, or *cinis antimonii*, is called by Grünling *terra sancta rulandi*. When not greatly calcined, it is grey, and, as Boerhaave tells us, violently emetic. When more calcined, it is, as usual, inert. The *flowers of antimony* have engaged, in a great degree, the attention of former chemists. The *various coloured flowers* of Lemery were produced by the unequal action of the fire on different parts of the metal, and were found to be violently emetic. The *red flowers* were sublimed with sal ammoniac, and the salt separated by washing. This preparation formed the basis of the *tinctura antimonii sicca* of Garman, and was of no great activity. The flowers, prepared by means of common salt, suggested the caution formerly mentioned. They were virulent in their operation; probably from some admixture of butter of antimony. We shall mention under this head only one other preparation, the *flos stibii helmontianus*. In this preparation the antimony was oxidated by aqua regia, and sublimed with sal ammoniac: it vomited violently; but, when washed, was milder. It was the *emeticus mitior* of Boerhaave.

The *sulphur auratum antimonii* and the *kermes mineral*, however, are the preparations which on the continent have obtained such extensive fame, and which foreign chemists have so strenuously laboured to improve. Indeed the former censure relating to the neglect of the kermes mineral in fevers, more generally must be confined to the English physicians. It was, we perceive, for many years the favourite febrifuge of the continent. The sulphur auratum antimonii is precipitated by quicksilver, dissolved in aquafortis, and thus forms the *mercurial sulphur of antimony* of Poerner, which he supposes highly useful in cutaneous complaints. Hoffman precipitates it by gold, dissolved in aqua regia, thus preparing the *sulphur antimonii solare*; and recommends it as a sudorific in venereal complaints. The *sulphur auratum liquidum* is a more modern, though operose, preparation. The sulphur auratum is dissolved in a caustic lixivium, and a soap prepared by adding oil of almonds or of poppies; and this is afterwards dissolved in a strong tincture of antimony. When it is recollected that the ancient physicians were so much attached to saponaceous remedies, it is not surprising that their prejudices and experience thus coinciding in a preparation should become a favourite. It was, in their opinion, aperient and deobstruent; sudorific and alterant; useful in dropsy, cancer, chronic exanthemata, and gout.

The *butter of antimony*, chiefly used as an external preparation, has been tortured in a variety of ways. It has been prepared with luna cornea instead of corrosive sublimate, and is then the *oleum glaciale lunare* of Lemery: with the martial, instead of the crude, regulus, it is the *martial butter of antimony*; and attempered by twice its weight of sulphuric acid, is styled *liquor pellegrini*. Sala's *spiritus mellis antimonio abstractus*, is only the butter of antimony in a milder form. The *oleum antimonii compositum* of Basil Valentine differs from the butter of antimony in the mode of preparation only, and the mixture of quicklime; which, as it does not rise in distillation, probably adds nothing to the pungency or efficacy of the application. The *balsam of antimony*, and the *liquor vulnerarius* of Basil Valentine, do not belong to this head: we mention them here only

as external applications. The glass of antimony in these preparations is united with distilled vinegar, evaporated to dryness, and mixed with the white of an egg. In this state it deliquesces, and then becomes the liquor vulcanarius.

The union of antimony with the vegetable acids forms, however, the most extensive list of preparations. The *magisterium antimonii idiaphoreticum* consists of the glass of antimony powdered and dissolved in distilled vinegar. If then joined with red coral, mother-of-pearl, and *hartshorn calcined*, 'seasoned' with the oils of cinnamon and cloves, it forms the *bezoardicum antimoniale* of Angelus Sala. We may just stop to remark in this place, that we find the union of hartshorn with antimony not uncommon among the earliest chemists, particularly in Angelus Sala, Schroeder, and in Hoffman's notes on Poterius, where he almost teaches the modern preparation of James's powder, and from whom Dr. James evidently caught the idea of his preparation.

In the *acetum emeticum* of Lemery the antimony is united to vinegar; and he remarks, that it is more effectual if prepared with crude than with distilled vinegar. The *tinctura ex croco metallorum* of Bicker is the crocus dissolved in vinegar, and inspissated to the consistence of honey. In different ways, the union of vinegar with the oxides of antimony has furnished the *vinum emeticum* of Lemery; the *aqua benedicta rulan-di*; *claretum purgatorium*; *vinum Hippocraticum antimoniale*; *symplicum vomitorium*; and the *oxysaccharum vomitivum* of Schroeder; the *tinctura antimonii acida* of Rosentengel; the *tinctura et elixir antimonii* of Basil Valentine; the *vinum antimoniale* of Huxham; and the *essentia emetica* of other authors. The *panacea universalis*, *panacea antimonialis emetica*, or *tartarus emeticus solubilis*, of Lemery, deserves a more particular notice. It is a neutral, composed of muriated and tartarised kali, with four parts of butter of antimony, eight of crystals of tartar, forty-eight of water, and five of salt of tartar. It is suffered to deliquesce in the air, and the nauseating dose is from six to twenty drops. Bergman's *tartarus tartarizatus emeticus* differs only from the emetic tartar, in employing the tartarised kali instead of crystals of tartar. We may just mention the *tinctura antimonii tartarizata* of Mayer; the *tinctura antimonii hepatica salina*, *tinctura antimonii* of other authors. It consists of wine digested with two parts of hepar antimonii; but, though highly commended, it seems to possess no very striking or peculiar properties.

Some preparations remain which contain scarcely any or no antimony except in their titles, or the antimony in an inactive state. The *antimonium diaphoreticum*, when powdered and washed in a linen bag, gives the *cream of diaphoretic antimony*. The *pulvis albus antimonii* of Basil Valentine is prepared by deflagrating the regulus three times with an equal weight of nitre, and washing it after each deflagration. Spirit of wine is to be eight times added, and again separated by distillation. After a process so operose, the preparation is useless. *Magisterium of diaphoretic antimony*, *materia perlata*, *sulphur fixatum stibii*, *sulphur antimonii fixatum*, *cerussa antimonii*, *cerussa antimonii diaphoretica*, *diaphoreticum regulinum*, and *antimonium diaphoreticum*, are appellations of a similar inert calx. The *cerussa antimonii so-*

*laris*, *diaphoreticum minerale solare*, *stomachicum poterii*, are pompous names for the highly oxidised and useless calx made from the solar regulus, and employed to attract the particles of quicksilver, which, after a long mercurial course, were supposed to be fixed in the fluids. A similar *cerusse* was prepared from the lunar regulus. The *antimonium diaphoreticum joviale* (*antihecticum poterii*) is a white calx, prepared from the jovial regulus, deflagrated with three parts of nitre. It is neglected as a remedy; and if it retain any powers, they are certainly not adapted to the complaint in its common form. We have used it without apparent injury; and in cases where the bronchial vessels were greatly relaxed we thought it useful as a tonic. The *antimonium diaphoreticum martiale* is the *pulvis anticachecticus* of Ludovici; the *stomachicum* of Poterius; the *pulvis vitalis* of Hall; and useless as an antimonial: but it contains some iron in an active state, though the martial regulus is deflagrated with three parts of nitre. The *mercurius vita correctus* of Sylvius, *bezoardicum minerale*, is prepared from the mercurius vitæ, deflagrated with three parts of nitre, and consequently inert. The *calx antimonii sine sulphure* consists chiefly of lime water, to which 0.11 of calx of antimony, and 0.02 of calx of iron, are added. The *flores antimonii nitrosi* are only the inert white oxide sublimed. The cinnabar of antimony differs in no respect from common cinnabar.

We shall add a list of other preparations in which antimony has been employed, and to which it has given a name; but they contain only a small portion, if any, of the metal, and certainly owe no part of their virtue to it. These are, 1. *Lilium paracelsi*, called by Stahl *tinctura antimonii acris et alkalinus*, *tinctura antimonii spuria* of Cartheuser. 2. *T. antimonii rubra* of Roger Bacon. 3. *T. vitri antimonii* of Lemery, and his *T. antimonii diaphoretici*. 4. *T. ex regulo antimonii martiali*; the *antidotos pantagogos* of Schroeder. 5. *T. antimonii Brixii*. 6. *T. antimonii nigri* (*mineralis amara*) of Urbiger. 7. *T. Antimonii saponata* Schulzii. 8. *T. antimonii Thedenii*. 9. *Oleum vitri antimonii*, *quinta essentia antimonii* of Basil Valentine. 10. *Antimonii febrifugum*, *magisterium antimonii*, *arcanum*, *elixir*, *balsamum*, *oleum sulphuris*, et *clyssus*, *antimonii*, of the same author. 11. *Acetum philosophorum ex antimonio*. 12. *Aqua stimmi tartarea* of Schroeder. 13. *Spiritus antimonii compositus* of the same author; *Sp. bezoardicus* Bussii; *Sp. vitrioli philosophicus* of Lemery. 14. *Sp. salis antimoniaci* of Basil Valentine. 15. *Sal verum*, and *flores antimonii* of the same; and, 16. the *chevalier's powder*.

This enumeration is nearly complete. Some of the most insignificant and ridiculous forms only are omitted.

ANTIMO'NII SULPH. REG. SUCC. See ANTIMONIUM.

ANTIMO'NII SPIRITUS. See CLYSSUS.

ANTIMO'NII RUBICUNDA MAGNE'SIA. See MAGNESIA OPALINA.

ANTIMONIA'LE CAU'STICUM. See ANTIMONIUM.

ANTIMO'NII ESSE'NTIA. See ANTIMONIALE VINUM.

ANTIMO'NII OLEUM. ANTIMO'NIUM MURIATICUM. See ANTIMONIUM.

ANTIMO'NIUM DIAPHORE'TICUM JOVIA'LE. See ANTIHE'CTICUM POTE'RRI.

ANTIMO'NIUM TARTARISA'TUM. See ANTIMONIUM.

ANTI'MORIS, (from *avti*, against, and *μωρος*, death or disease). A medicine to prolong life. Also the

name of an antidote which Myrepsus improperly calls *diatamaron*.

**ANTINEPHRITICA**, (from *αντι*, and *νεφριτις*, a pain in the kidneys). Remedies against disorders of the kidneys. See **NEPHRITIS**.

**ANTIPARALYTICA**, (from *αντι*, against, and *παρالىσις*, the palsy). Medicines against the palsy. See **PARALYSIS**.

**ANTIPATHES**. A BLACK CORAL. See **CORALLIUM NIGRUM**.

**ANTIPATHEIA**, (from *αντι*, against, and *παθος*, an affection). **ANTIPATHY**. An aversion to particular objects. It is doubtful whether there is any real foundation for feelings of this kind; yet, when we reflect that some animals, as toads or serpents, are generally objects of antipathy, we cannot wholly attribute the aversion to fancy, though we cannot explain it. Form, colour, but, above all, disproportion, excite it.

**ANTIPERISTASIS**, (from *αντι*, and *περισημι*, to surround). A compressing on all sides as the air presses.

**ANTIPIIA'RMICUM**, (from *αντι*, against, and *φαρμακον*, poison). An ANTIDOTE, or PRESERVATIVE against poison. See **ALEXIPHARMICA**.

**ANTIPHLOGISTICA**, (from *αντι*, against, and *φλεγων*, to burn). **ANTIPHLOGISTICS**. Medicines or remedies suited to resist, diminish, or cure inflammation, or an inflammatory diathesis of the constitution. Under this head may be classed all watery diluents, cooling saline diaphoretics, and diuretics, particularly nitre; antimonials in small doses; and BLEEDING, general and topical. See **PHLEBOTOMIA**, **CUCURBITULA**, and **HIRUDINES**. Besides, living on watery, cooling vegetables, drinking copiously of simple watery liquids, and abstaining totally from all animal food and stimulating diet, may be classed not amongst the weakest of the materials proper for promoting the desired intent, under circumstances where antiphlogistics are required.

**ANTIPHTHISICA**, (from *αντι*, against, and *φθισις*, a consumption). Remedies against a consumption. See **PHTHISIS**.

**ANTIPHTHISICA TINCTURA**; i. e. **TINCT. SATURNINA**. See **PLUMBUM**, N° 5.

**ANTI'PHTHORA**, (from *αντι*, against, and *φθορα*, corruption). A species of wolf's-bane, which resists corruption.

**ANTIPHY'SICA**, (from *αντι*, against, and *φυσω*, to blow). Remedies against wind. See **CARMINANTIA**.

**ANTIPHY'SON**, (*αντι*, against, and *φυσις*, nature,) so called, because the loadstone acts against the common appearances of nature. See **MAGNES**.

**ANTI'PLEURITICUM**, (from *αντι*, against, and *πλευριτις*, a pleurisy). A remedy against the pleurisy. See **PLEURITIS**.

**ANTI'PODAGRICA**, (from *αντι*, against, and *ποδωγρα*, the gout). Medicines which relieve or remove the gout. See **ARTHRITIS**.

**ANTI'PODAGRICUM**, **BALSAMUM**. See **ANODYNUM BALSAMUM**.

**ANTI'POPLE'CTICA**. See **APOPLECTICA**.

**ANTI'PRA'XIA**, (from *αντι*, against, and *πρασσω*, to work). A contrariety of functions and temperaments in different parts, used by the ancients to express the variety of concurring, and often contrary, symptoms.

**ANTI'PYRE'TICON**, **ANTI'PYRE'TON**, (from *αντι*, against and *πυρετρος*, a fever). A remedy against a fever; called also *antihyrcuticon*.

**ANTIQUARTANA'RIMUM**, or **ANTIQUA'R-TIUM**, (from *αντι*, against, and *quartanum*, a quartan fever). A medicine against a quartan.

**ANTI'RRHINUM**, (from *αντι*, against, and *ρις*, the nose,) also called *caput vituli*, *bucranion*, *os leonis*, *anarrhinum*, *lychuis*, *sylvestris*, *atochium*, **SNAP-DRAGON**, and **CALF'S SNOUT**.

A decoction is said to be used in the jaundice, but is chiefly used as a charm.

**ANTI'RRHINUM LINA'RIA**. See **LINARIA**.

**ANTISCO'LICA**, (from *αντι*, against, and *σκοληξ*, a worm). See **ANTHELMINTICA**.

**ANTISCORBU'TICA**, (from *αντι*, against, and *scorbutus*, the scurvy). Medicines against the scurvy; q. v.

**ANTISCORBU'TICUS**, **CORTEX**. See **WINTERANUS**, **CORTEX**.

**ANTISE'PTICA**, **ANTISEPTICS**, (from *αντι*, against, and *σηπτικα*, septic or putrifiers). What resists or corrects putrefaction. Complete putrefaction cannot be an object of practice, because it cannot take place in any considerable portion of the body without extinguishing life: it is, therefore, a tendency to it in any considerable degree, which, producing various morbid disorders, requires the utmost aid of the medical art. As this tendency may be brought on by excess of heat and motion, as well as receiving any ferment into the vascular system; as, when once fixed, and exerting its deleterious action, it induces great languor and debility in the moving powers; we perceive why our antiseptic class of medicines exhibits such apparently contradictory views; for we find both volatile and neutral salts in the same arrangement: the former considered as highly heating, and strongly stimulant of the moving powers; the other, cooling the system, and mitigating vascular action. Hence, then, it is apparent that they are only applicable in different states of putrescent action, or in different constitutions affected with putrescency. It is the same with acids and alkalis; for these both are enumerated under antiseptics. They have been properly divided into five heads:—1st. Such as are cooling; acids, and neutral salts. 2d. Stimulant; wine, alcohol, oil of turpentine, spices, salt of amber, alum, terra Japonica. 3d. Tonic; Peruvian bark, wormwood, camomile. 4th. Antispasmodic; camphor, asa-fœtida, musk. 5th. Dietetic, commonly styled *antiscorbutic*. These furnish examples of the particular divisions; and, from their nature, we shall readily know in what particular states each is applicable: where there is peculiar sensibility in the stomach, the TONIC are to be avoided; the REFRIGERANT, where a debility of the vital powers is manifest; the STIMULANT, when there is too great a degree of irritability, the circulation too highly accelerated, with a strong disposition to profuse bleeding; the SEDATIVE ANTISPASMODICS, when there is too languid a circulation, a lethargic disposition, or a considerable degree of torpor in the system.

See Macbride's Essay on the respective Powers of Antiseptics, Remarks on Mr. Alexander's Essays on Putrid Diseases. Cullen's *Materia Medica*. Wallis on Health and Disease.

**ANTISPA'SIS**, (from *αντι*, against, and *σπασω*, to

*draw*). A REVULSION. The turning the course of the humours whilst they are actually in motion. The doctrine of revulsion is the invention of Hippocrates.

ANTISPASMO'DICA, (from *αντι*, *against*, and *σπασμος*, *a convulsion*). This class of medicines must be ranked among the more irregular and anomalous groups, as the individuals are adapted to a set of symptoms arising from a variety of causes, and not to a particular end or object. The causes of spasm differ essentially, and the remedies must equally differ. Spasm is obviously irregular action; and, from what we have already hinted, irregular action is commonly the effect of weakness. See ANODYNES. In this view antispasmodics must be tonics and stimulants. This, however, though an obvious, is a partial, result of the premises. When action is irregular, we may equally restore the equilibrium by stimulants and by sedatives; more often by the powerful effect of sedatives, which, by stopping all action, enable us to commence it more regularly. Thus in ileus, where strong spasm, and in consequence inverted motion, take place, we succeed better by stopping all muscular exertion, and again commencing the stimulus from above downwards, than by forcing the peristaltic motion in an opposite direction to that which has morbidly taken place. If, then, we were to fix on any general determinate action of antispasmodics, we would say that they were sedatives. Experience, however, corrects such hasty theoretical conclusions; and we shall find that they are sometimes stimulant, more frequently tonic, but most often sedative. Yet there is a class highly useful, referring to neither, the fetids, which we need not enlarge on at this moment, but shall treat of them in turn, under the appellation of *anomalous*.

The stimulant antispasmodics are not numerous. The chief are electricity and Galvanism. It is an unavoidable inconvenience in a dictionary, that we must anticipate what is afterwards to be fully explained, and the only remedy is, to give shortly the result of reasoning which is at a future period to be more carefully pursued. We shall find that the electrical fluid, and the Galvanic, (if not the same with that which gives activity to the nerves, certainly nearly allied to it,) excite the powers of life by their passage through the nerves. These, then, are stimulant antispasmodics; for they correct the irregular action of muscular fibres with considerable success. Volatile alkali acts, in many instances, very powerfully as an antispasmodic. Æther and ardent spirits are more equivocal; yet, as their action is immediate, we would refer them to the same head. Some other remedies are equally doubtful: we allude to quicksilver and iron. A very extensive view of the action of metals inclines us to consider the whole class as tonics; yet mercury certainly keeps up a steady increased action of the sanguiferous system, and iron, though less pointedly, is of a similar nature. We shall have occasion to explain all the powers of these metals on this principle; and, therefore, must arrange them in this order of antispasmodics.

The tonic antispasmodics are very numerous. Of this kind are the whole metallic tribe with the exceptions just mentioned, viz. arsenic, zinc, copper, and silver. Bark, of course, belongs to this order; and the viscus quercinus, the balsamum Peruvianum, and cold

bathing, will not be refused a place in the same arrangement. The sedatives are also numerous and powerful. Bleeding ranks the highest, and opium follows. No other remedies can claim an equal credit; but warm bathing, fear, and other depressing passions, camphor, the flores cardamines, and, perhaps, hydrogenous gas, have no inconsiderable claims to our attention in the same way. Blisters, as explained under the article of ANODYNES, are sedative, by lessening the irritation of the sanguiferous system.

The anomalous antispasmodics include the fetids. These, from their effects, we suspect to be sedatives. When breathed, the want of elasticity in carbonic acid and hydrogenous airs gives the sensation of suffocation; and many of these show, in other instances, sedative effects, particularly the asafetida; the sweet oil of wine, the most active part of Hoffman's anodyne and Tickell's æther; the fetid herbs (including the rue, savine, atriplex olida, and aristolochia), petroleum; ambergrise; the fumes of burnt feathers; musk, and civet.

Since we have considered blisters as taking off internal irritation, we might also, in a more general view, consider bleeding as a cause of derivation from a part unusually loaded, and perhaps irritated. Yet we chose to consider it separately, since we would connect this with a very different class of remedies, viz. those which act by arresting the attention, and, of course, breaking the habit. Spasmodic diseases soon become habitual; and when the cause is removed, the paroxysms recur from habit only. Bleeding, either from association or the terror of the operation, acts in this way; and Dr. Whytt has remarked, that a person, usually relieved by bleeding, has experienced the same relief on puncturing the vein. Keeping the attention alive has had a similar power; and it is remarked, that during a siege a town has been peculiarly free from nervous complaints. Sudden terror has been equally effectual; and we thus account for the effects of numerous superstitious remedies formerly recommended.

In another view, emollients and demulcents are antispasmodic; for when the more sensible mucous membranes are inflamed, and the more fluid mucus rapidly carried off, they are morbidly irritable; and from the common stimuli, irregular action is often excited. Causes of this kind sometimes produce spasmodic colics, and what are styled nervous coughs.

In the choice of these we employ the sedatives and fetids to shorten the fit; the stimulants and tonics to prevent returns. The stimulants, when employed in this way, are exhibited in more constant and less active forms, and then, probably, approach the nature of tonics.

ANTISPA'STICON, (from *αντι*, *against*, and *σπασω*, *to draw*). A general epithet for any medicine that acts by way of revulsion.

ANTISTE'RNON, (from *αντι*, *opposite to*, and *στρονον*, *the sternum*, or *breast*). The back is so called because it is opposite to the breast bone. See DORSUM.

ANTI'TASIS, (from *αντι*, *against*, and *τεινω*, *to extend*). A CONTRA-EXTENSION: an opposite location of parts, as of the liver and spleen.

ANTI'THENAR, (from *αντι*, *against*, and *θεναρ*, *the palm of the hand*). See ABDUCTOR POLLICIS MANUS INDICEM.

Dr. Hunter applies this name to a muscle of the foot, and says it arises from the os cuneiforme, and is inserted in the external sesamoid bone.

ANTI'THORA. See ANTHORA.

ANTITRA'GICUS, ANTITRA'GUS, (from *αντι*, against, and *τραχος*, the thick part of the anthelix). See AURICULA.

ANTITYP'US, (from *αντι*, and *τυπω*, percutio). See RENISUS.

ANTIVENE'REA, (from *αντι*, against, and *venereus*, venereal). Medicines against the lues venerea.

ANTIVENEREAL'IS, AQUA PRESERVATI'VA. It is a solution of caustic alkali, or corrosive sublimate, in water, to be injected up the urethra in men, and the vagina in women, and to wash the parts with after coition; but care must be taken that the solution should not be too strong lest it should occasion excoriation and inflammation. It will be sufficient if it be of such a strength only as will give a slight sensation of pungency on the tongue, or inside of the lips.

It has been suspected, that checking the discharge of gonorrhœa may induce hernia humoralis, or syphilis. We cannot deny that these have been sometimes the consequence; yet if the disease be taken in its early stages, we have not found such consequences. We know that a caustic applied very early to a chancre will check all further infection; and there is no reason why the discharge of mucus, excited by the preservative water, may not be equally effectual.

ANTIZEU'MIC, (from *αντι*, against, and *ζυμη*, ferment). Preventers of fermentation in general.

ANTONIAN, a mineral water of Germany, containing carbonated soda, common salt, and calcareous earth; the latter seemingly dissolved by an excess of carbonic acid gas.

ANTO'NI SANC'TI I'GNIS. ST. ANTHONY'S FIRE; so called, because St. Anthony was supposed to cure it miraculously; but in the Roman missal, St. Anthony is employed as being the preserver from all sorts of fires. See ERYSIPELAS.

ANTONOMA'STICA. See COCHLÆA CÆLATA.

ANTOPHY'LLON, or ANTOPHY'LLUS, (*αντι*, opposite, and *φυλλον*, a leaf,) so called because its leaves stand opposite one another. The MALE CARYOPHYLLUS, or the large full-grown ones. See CARYOPHYLLI AROMATICI.

A'NTRUM BUCCINO'SUM. See COCHLEA.

A'NTRUM GENÆ, ANTRUM HIGHMORIA'NUM MA'GNUM, called also *sinus maxillaris*, and *antrum maxillæ superioris*. MAXILLARY SINUS. Highmore boasts of the discovery; but Casserius takes notice of this part before him, under the first name.

A'NTRUM PYLORI, the great concavity of the stomach approaching the pylorus.

All the body of the upper jaw bone is hollow, and its cavity forms this antrum; each hath a winding passage into the nostril, called *ductus ad nasum*, on the side on which it lies; this cavity and the sockets of the teeth are often divided by the interposition of only a very thin bony plate. The membrane which lines this cavity is sometimes inflamed, and matter forming in it is discharged by drawing one of the dentes molares. See ABSCESSUS SINUS MAXILLARIS.

ANTY'LION. The name of an astringent used by P. Ægineta; so called from Antyllus the inventor.

A'NUCAR. See BORAX.

ANUS, called also *archos*, *culus*, *hedra*, *podex cyræon*, *cyssaros*; and in Hippocrates, *cathedra*; some name it *perin*. It is the lowest part of the intestinum rectum, commonly called the FUNDAMENT. The extremity of the rectum contracts into a narrow orifice, the sides of which are disposed in close circular folds. This is called SPHINCTER ANI, which see. It hath several muscles belonging to it, some of which surround it as sphincters; the rest are broad, and fleshy planes inserted in it, and which, being inserted likewise into other parts, sustain it in its natural situation, and restore it when disturbed by the force necessary for excluding the fæces: the latter muscles are termed *levatorès ani*. Two ligaments belong to the *anus*, viz. the ligamentum cutaneum ossis coccygis, and the ligamentum pubis interosseum. See LIGAMENTUM. The nerves of the *anus* and its muscles are from the ganglions of the plexus hypogastricus, the inferior cord of both the sympathetic maximi, and the common arch of the extremities of both cords. The margin or edge of the *anus* is a continuation of the skin and epidermis, with the internal coat of the intestinum rectum. This part is extremely vascular; and a troublesome hæmorrhage, when the operation is performed for the fistula in this part, often ensues.

The *anus* is subject to many disorders, and they are generally somewhat difficult of cure, because of the irritability of the part, which subjects it to receive fresh injury from many accidents. Aëtius observes, that astringents which are acrid, the sensibility of the *anus* cannot bear; and that astringents which are not acrid, such as metals, should be applied. On the diseases of this part, see Aëtius, Celsus, P. Ægineta, Turner, Heister, and Wiseman. See also RECTUM. Discharges of wind from the anus are called *crepitus*.

#### EXCRESCENCES ABOUT THE ANUS.

Various excrescences are found about the verge of the *anus*; many of these, produced merely by relaxation and safely removeable, are unattended with pain, or any disagreeable discharge, and are single or distinct, whatever their number be. In removing them, the ligature, to avoid a troublesome hæmorrhage, is preferable.

When they discharge a bloody fluid matter and are painful, they are also generally in clusters, or not distinct; and for the most part disposed to be, if not already become, cancerous. Mr. Pott observes, that in cancerous cases of this kind there is rarely a single excrescence, but the gut is for the most part surrounded with them; and if a finger is passed into the intestine, those tumours produce the idea of pushing the finger into a rotten pomegranate. Beyond palliation, no relief can be afforded.

#### The ANUS IMPERFORATED.

Sometimes children are born with a membrane across the *anus*, which obstructs the discharge of the excrements. If the situation of the *anus* cannot be discovered in consequence of the thickness of the superfluous substance which closes it up, a cure cannot be expected; for much, if not the whole rectum, is closed up or wanting. If the case admits of a cure, the situation of the *anus* will be seen by a prominence, or by a little hollow.

This accident is generally spoken of as if always cir-

cumstanced alike. Mr. Pott very judiciously divides it into four classes. 1st. Where there is no mark or vestige of an *anus* perceptible: in this case the rectum is as it ought to be until it arrives at the bulb of the urethra; from this there is no intestine, and no *anus* externally. If the rectum reaches too near the part where the *anus* should be, the impulse of the feces against the skin will discover where a perforation may be made; but if no such impulse is to be felt, when the child coughs or cries, relief cannot be afforded. 2d. Where there is a circle or mark in the skin which points out where the *anus* should be: in this instance the difficulty is not considerable. However, it may be proper to add, that the perforating instrument should be introduced in the direction of the os sacrum; if it passes forward, the bladder, or the uterus, or both, may be injured; if it is to be introduced far up, to divide a membranous obstruction in the rectum, in cutting it should be moved not upward, but from side to side; thus you avoid wounding the prostate gland, or the vesiculæ seminales, and perhaps the neck of the bladder. 3d. Where there is a well formed *anus*, and perforated, but no communication with the intestinal tube, from the rectum being imperforated, if the child is not duly attended to, it dies in great agonies. If an infant hath had no stools during the first or second day after its birth, a finger should be dipped in oil, and thrust up the rectum, to discover whether any obstruction is there. 4th. Where there is neither *anus* nor rectum, but the intestinal canal terminates in the colon, no relief is to be expected. Another equally unfortunate kind is when a sort of rectum is rolled up like a bit of catgut. Here all attempts to assist are vain; for though a discharge should be obtained, as the intestine is deficient, evacuations could not be continued.

The means of relief, in the first three of the above classes, are the same. In either of them the operation should be performed without delay or regard to any objections; for, otherwise, death will inevitably follow. The best instrument is a large trocar, such as is employed for tapping in the ascites. The point of the trocar must be kept within the canula until it is fixed against the obstructing part; then pushed forward; and, if you succeed, the meconium will instantly be discharged: this discharge may be left to itself for three or four hours, or until the belly is well emptied. Afterwards pass a finger up the rectum, to discover whether there is any stricture. If a stricture is met with, introduce a probe pointed knife on the back of your finger, and divide it on each side. To finish the cure, let a small candle be introduced up the gut every two or three hours, or kept there until the *anus* is quite pervious, and no more aid appears to be required. In two or three weeks the stools will pass properly, and all inconvenience will generally be ended. See Bell's Surgery, vol. ii. p. 275. Edinb. Med. Comment. vol. iv. p. 164. White's Surgery, p. 379.

**A'NUS ARTIFICIAL.** This artificial aperture is generally at the ring of the abdominal muscles, in consequence of a hernia. It has occasioned many discussions in the works of the later German surgeons, particularly Richter and Loeffler; but the management cannot be easily described. Its formation must, when an union of the two ends of the divided intestine cannot be effected, be left to nature; and the little conveniences

to be added, must depend on contrivance, rather than medical skill.

**A'NUS**, a contraction of *annulus*, a ring.

**A'NUS.** See *CEREBRUM*.

**A'NI ABSCE'SSUS.** See *ABSCESSUS*.

**A'NI INFLAMMA'TIO.** See *PROCTALGIA*.

**ANTITYPUS**, (from *αντι*, against, and *τυπος*, ductile). A hard substance which resists pressure; as a node. See *RENISUS*.

**ANXIE'TAS**, (from *ango*, to torment). See *ALYS-MOS*.

**ANYPEU'THYNA**, (from *α*, neg. and *πενθος*, hurtful). In medicine this signifies events that cannot be charged on the physician, who is not, of course, accountable for them.

**AORTA**, (*αορ*, air, and *τερω*, to hold). The term *aorta* was used by the ancients, who supposed that only air was contained in it. The name of the great artery proceeding from the left ventricle of the heart, of which all other arteries, except the pulmonary, are the branches: called also *crassa arteria*; *magna arteria*. From the heart it extends itself, by various branches, to the most distant parts of the body. Each of the divisions and subdivisions of the *aorta* receives a different name, e. gr. the *aorta* gives rise to the carotid and the subclavian arteries, the branches of these again receive other names. These branches are in pairs, except the cœliaca, the two mesentericæ, some of the œsophageæ, the bronchialis, and sometimes the sacræ.

The beginning of the *aorta* is furnished with semilunar valves, as the pulmonary artery; and the same triangular bodies close up the little space left by the valves. It is larger in women than in men. It is called the ascending *aorta* from the heart, so far as it goes upwards; and descending, from its curvature downwards, to the os sacrum, where it terminates in the iliacs. The descending *aorta* is divided into the superior, which reaches from the curvature to the diaphragm; and the inferior, which extends thence to the bifurcation, where the iliacs begin.

The *aorta* goes from the basis of the heart, nearly opposite to the fourth vertebra of the back, and ascends obliquely, with respect to the body, from the left to the right side, and from before backwards; then bends obliquely from the right to the left side, and from before backwards, reaching as high as the second vertebra of the back, from whence it runs down again in the same direction, forming an oblique arch. From this it descends in a direct course along the anterior part of the vertebræ, all the way to the os sacrum, lying a little towards the left hand, and there terminates in its two subordinate branches in the iliacæ.

The *aorta ascendens* is principally distributed to the thorax, head, and upper extremities: the superior portion of the *aorta descendens* furnishes the rest of the thorax: the inferior portion furnishes the abdomen and the lower extremities.

The *aorta* is subject to many disorders, as inflammation, ulcers, polypuses, aneurisms, ossification, &c.

**APA'GMA**, (from *απο*, and *αγω*, to draw from). See *ABDUCTIO*.

**APALACH'NE GALLIS**, (from *απαλακω*, to repel, because it is supposed to repel infection). See *CASSINE*.

APA'LLAGE, (from *απαλλάσσω*, to change). Hippocrates means by it such a change as implies deliverance from a disease.

APANCHIO'MENOI, (from *απο*, and *αγγω*, to strangle). STRANGLED, or SUFFOCATED.

APANTHISMUS, (from *απανθω*, to grow thin). A scarcely perceptible line in paintings, to which Galen resembles the small capillary veins.

APANTHRO'PIA, (of *απο*, from, and *ανθρωπος*, a man). An aversion to company, or love of solitude; generally a symptom of melancholy.

APARACHYTUM VINUM, (from *α*, neg. and *παράχω*, to pour upon). Wine not mixed with sea water.

APAREGORE'TOS, (from *α*, neg. and *παρηγορεω*, to comfort, mitigate). What affords no comfort or relief.

APARINE, (from *ρίνη*, a file; because its bark is rough, and rasps like a file). Called also *philanthropus*, *amphelocarpus*, *omphalocarpus*, *ixus*, *asparine*, *asperula*, GOOSE-GRASS, and CLEAVER'S BEES. CLEAVERS, GOOSE-SHARE. HAYRUFF. It is the *galium aparine* Lin. Sp. Pl. 157.

This plant has been tried in scrofula, but without success; and in some cancerous cases, the juice given internally, and the herb applied in a cataplasm externally, has been supposed to mitigate the severity of the pain. An extract made of its juice is possessed of a pungent saline bitterness. The fresh juice, in doses of two or three ounces, is slightly diuretic. It is best if gathered when half grown. The whole plant is however inert, and scarcely ever employed.

APARINE LATIFOLIA. See ASPERULA.

APARTHRO'SIS, (from *απο*, ab, and *αρθρον*, a joint). See ARTICULATION.

A'PATHES, (from *α*, neg. and *παθος*, an affection, or passion). Those who seem to be void of human passions, instanced in Diogenes the Cynic, and Timon.

APATHIA, (from *α*, neg. and *πάσχω*, to suffer). APATHY expresses the quality of not feeling, a freedom from the impulses of passion and mental perturbation.

APECHE'MA, (from *απο*, and *ηχος*, a sound, *apochorhema*). Properly a repercussion of sound; but in medical sense it signifies a CONTRA-FISSURE, or FRACTURE.

APEIROI', (from *α*, neg. and *πειρα*, an experiment). UNEXPERIENCED, UNACUSTOMED.

APE'LLA, (from *α*, priv. and *pellis*, skin). Shortness of the prepuce. Galen gives this name to all whose prepuce, either through disease, section, or otherwise, will not cover the glands.

A'PEN, (Indian). A sort of bread made with the juice of the ambalam tree and rice in India.

APE'NSALUS. A vessel with a narrow neck to hold oil.

APEPSIA, (from *α*, neg. and *πέπω*, to digest; also *dyspepsia*). INDIGESTION. That genus of disease which Dr. Cullen names *dyspepsia*, he arranges in the class *neuroses*, and order *adynamia*. The symptoms are, a want of appetite, a sickness, sometimes vomiting, sudden and transient distentions of the stomach, eructations, heartburn, pain in the region of the stomach. These symptoms, or the greater number of them, are attended most commonly with costiveness, without any other disorder either in the stomach itself, or any other

part of the body. In this case, when what ought to be digested and form materials for good chyle becomes acid, or putrid, a variety of other symptoms occurs, according to the nature of the materials thus morbidly changed. But indigestion is very frequently a secondary and sympathetic affection, though the just mentioned symptoms are essential to this disease, as idiopathic. All these may arise from one cause, viz. weakness, or loss of tone in the muscular fibres of the stomach: and this weakness is the proximate cause of the disorder, when an original one. The remote causes are various, as tumour, in the stomach itself; or some disorder of other parts communicated to the stomach, as in the gout; in these cases the indigestion is symptomatic.

In most instances of indigestion, as an original disease, the weaker action of the muscular fibres of the stomach is the chief cause; a depravity or defect of the gastric juice has been supposed to occasion it; but even here, perhaps, weakness is the only cause to which we can attend usefully in practice. To succeed in the cure, we must avoid the occasional causes, remove such symptoms as tend to aggravate or to continue the disease, and invigorate the tone of the stomach. For this purpose the patient must be informed of the necessary changes in his conduct; for though he has often pursued such a practice without sensibly suffering, except he conforms to a contrary one, the present complaints will not be removed. Crudities, acidity, and costiveness, must be obviated at least in their excess, as they tend both to aggravate and continue indigestion. When these ends are accomplished, the restoration of the tone of the stomach alone remains for perfecting relief.

Abstemiousness and excess, but chiefly the latter, are causes of indigestion. An over-distention of the stomach may in some measure injure its proper tone; and frequent long fasting, render it feeble. Hard drinking, and any of the causes of an anorexy, also injure digestion. Fasting, however, must be long continued, and frequently repeated, to have any bad effect. When it produces dyspepsia, improper food has been occasionally taken.

Anxiety and uneasiness of mind are often remote causes of dyspepsia, and when these are removed, the effects often continue. Intense study, not properly alternated with cheerful conversation or exercise, has the same effect; but no remote cause is more frequent or powerful than late hours, and indulgence in spirituous liquors. In these cases the management of diet is of considerable importance; and they form one of the very few exceptions to the general rule of suffering the stomach to be occasionally empty. When it is so in dyspepsia, all the symptoms are aggravated; and persons labouring under this complaint should frequently swallow some food. A bit of ship biscuit, as bread not subject to fermentation, is one of the best substances to be frequently taken, and a little beef tea may be also occasionally added. The food should in general be of the light animal kind, and the more flatulent vegetables and fruits avoided. The drink should be porter, or strong, not sweet, cyder; and the wine, Madeira or sherry. If these cannot be obtained, a slight addition of good brandy to cold water, without sugar, may be allowed. Tea should be at once abandoned; and an

infusion of our own warmer herbs, as pennyroyal, pepper-mint, or rosemary, substituted.

In some weak stomachs a singular aggravation of the symptoms comes on, in about an hour or two after a tolerably full meal, attended with a sense of sinking or weakness. This seems to be owing to a digestion unusually rapid, and consequently imperfect. In such cases, aliment of more difficult digestion, as eggs boiled hard, or the addition of condiments which retard digestion, may be allowed; but, in general, a bit of biscuit and a glass of wine will remove the sense of weakness, which is owing to the sudden emptying of the stomach before too much distended.

Little need be added in order to the cure; for the treatment is the same as is required in ANOREXIA, q. v.

THE COLUMBO ROOT, not mentioned in the article ANOREXIA, is particularly useful when the stomach is languid, the appetite defective, digestion with difficulty carried on, or when a nausea with flatulence attends. It may be given in substance with any grateful aromatic, or infused in Madeira wine, now and then interposing gentle doses of the tincture of rhubarb.

A mixture of mustard seed with the columbo root is of considerable utility in complaints of this kind; particularly where acidity and flatulence prevail much in the primæ viæ; and the aqua kali puræ always assists its action: a warm plaster, with the addition of some opium, worn at the pit of the stomach, is occasionally of great service.

The Bath waters, assisted with warm nervous medicines and corroborants, are not to be omitted when circumstances admit of their use.

See Percival's Essays in the Reflections on Exper. 4, 5, and 6. Cullen's First Lines, v. iii. p. 217. edit. iv.

APE'PTON, (*α, priv. and πεινω, to digest*). CRUDE OR INDIGESTED.

A'PER. THE WILD BOAR. See PORCUS, and ALIMENT.

APE'RIENS PALPEBRA'RUM RECTUS. See LEVATOR PALPEBRÆ SUPERIORIS.

APERIE'NTIA, APERIENTS, (*from aperio, to open*). These are medicines supposed to have the power of opening the mouths of vessels, and clearing vascular or glandular obstructions. In this sense they are synonymous with the *anastomatica*, *deobstruentes*, and *deopulativa*. But those medicines which render the bowels gently laxative are now generally called *aperients*; the removal of other obstructions is more confined to the term *deobstruents*.

In the writings of the ancient physicians, particularly the practitioners of the Boerhaavian school, aperients were considered as medicines of peculiar importance, and many vegetable substances of little real powers were arranged under this head, and supposed to act in consequence of a saponaceous principle. These are now disregarded; yet modern practice still adheres to some of these in jaundice and hepatic obstructions, though they seem to have little effect, except as gentle laxatives.

APERI'STATON, (*from α, neg. and περιστασις, affliction and danger*). An epithet in Galen for an ulcer that is neither troublesome nor dangerous.

APERI'TTOS, (*from α, neg. and περιττος, redundant*). Such aliment as generates but little excrement. The opposite quality is called *perittomaticos*.

APE'RTUS, (*from aperio, to open*). It is used for *exulceratus*, as in saying an open cancer, &c. in which cases the tumour is ulcerated.

A'PES, (perhaps from *apio, necto, to join together*; because, connected together by the feet, they hang down from the entrance of the hive). BEES; called by the ancients BUGONES, q. v.

If they are dried and powdered, they are somewhat diuretic; but their chief use is for the preparing of honey and wax.

APEUTHY'SMENOS, (*from απο, and ευθς, strait*). See RECTUM INTESTINUM.

APHE'REMA. See ALICA.

APHÆ'RESIS, (*from αφαιρεω, to take away*). To take away any superfluous part, medicinally or surgically.

APHASSIO'MENOS, (*from αφασσω, to handle*). To reduce any thing to a pulp or powder by rubbing it between the fingers. Hippocrates often applies this word to the touch of the pudenda, in order to discover disorders of these parts. It is the same as TACTUS.

APHE'BRIOC. SULPHUR.

APHELICE'STEROS, (*of απο, from, and ηλικια, youth*). One past the flower of age.

APHEPSE'MA, (*from απο, and εψω, to boil*). See COCTIO.

APHE'SIS, (*from αφημι, to remit*). Hippocrates generally signifies the remission or solution of a disease by this word.

APHILANTHRO'PIA, (*from α, neg. and φιλανθρωπια, the love of mankind*). The first degree of melancholy, when a person hates society, and delights in solitude.

APHLEGMA'NTON, (*from α, neg. and φλεγμα, phlegm*). VOID OF PHLEGM.

APHO'NÆ. See PEMPHIGODES.

APHO'NI, (*from α, priv. and φωνη, voice*). Those who labour under a coma. Hippocrates.

APHO'NIA, (*from the same*). See CATALEPSIS. It is also a name for the palsy of the tongue; one of the species of partial palsy. See PARALYSIS; called by some *anaudia*, see ANAUDOS, though Galen distinguishes them.

Dr. Cullen speaks of this loss of voice as a suppression of the full sound, which happens without coma or syncope. He ranks this genus of diseases in the class *locales*, and order *dyscinesia*, and observes three species, viz.

1. APHO'NIA GUTTURALIS; when the glottis and fauces are swelled.

2. APHO'NIA TRACHEALIS, when the trachea is compressed.

3. APHO'NIA ATONICA, when the nerves of the larynx are wounded. He also, in many cases, considers it as symptomatic.

If one of the recurrent nerves, formed by the par vagum with the nervus accessorius, extending to the larynx, is cut, the person is capable of only an imperfect pronunciation; but if both are cut, the speech and voice are lost. The loss of speech happening in hysteric patients is also called *aphonia*; but more properly that loss of speech is thus named which depends on some fault of the tongue.

As the motion of any part is destroyed, or lessened at least, by the interception of nervous influence, and as the nerves destined for the motion of the tongue arise

principally from the fifth pair, it appears that the seat of this disorder is in these nerves, and that the immediate cause is a diminution or total loss of nervous energy. Hence, a palsy of the tongue, which is either antecedent or subsequent to hemiplegic or apoplectic disorders, demands our utmost attention.

If an *aphonia* appears alone, it generally shows an approaching hemiplegia or apoplexy; but if it succeeds these disorders, and is complicated with a weak memory, and a sluggishness of the mental powers, it threatens their return. That *aphony* usually terminates most successfully, which proceeds from a stagnation of serous humours compressing the branches of the nerves which run to the tongue; but it is equally distressing and obstinate.

Other causes of this disorder are, repelled eruptions on the skin, obstructed periodical evacuations in plethoric habits, spasmodic affections, worms, fear, too frequent use of spirituous liquors, and whatever destroys the ligaments from the aretæoid to the thyroid cartilages.

The prognostics vary according to the causes. That species which is owing immediately to spasms soon gives way in the removal of them. If a palsy of the tongue is the cause, it is very apt to return, if relieved; but often continues incurable.

In directing the cure, we must endeavour first to remove whatever impedes the nervous influence on the tongue; and secondly, to strengthen the weak parts. The particular causes must be next considered.

If worms are the cause, antispasmodics give temporary relief; but the cure depends on the destruction of these vermin. However, they seldom occasion the disease.

In congestions of blood about the head, bleeding, general and topical, with blisters constantly kept open, and active laxatives, are the best remedies.

That species of *aphony* which remains after the shock of an hemiplegia or apoplexy, particularly requires blisters to be applied to the nape of the neck, or under the fauces: other means are rarely effectual.

If spasmodic constrictions about the fauces and tongue are the cause, applications of opium are of the greatest service: anodyne antispasmodics may be laid under the tongue, and the feet bathed in warm water; carminative clysters also are useful; and ʒij. of asafœtida may be dissolved in four ounces of warm water for this purpose.

When a palsy of the tongue produces this complaint, evacuations, according to the patient's habit, must be made, and warm nervous medicines externally applied, and internally administered; blisters also should be placed on the nape of the neck; and the patient should be constantly chewing bits of ginger, or biting corns of black pepper. Warm tonics are also highly proper.

In case of repelled cuticular eruptions, sudorifics should be given, and the patient's drink should be warm. The liquor c. c. succinatus, or the vin. antimonii may be mixed with tinctura benzoës composita, or with the balsamum Peruv. and given, at proper distances, in the patient's drink, or on a lump of sugar. In general, however, the eruptions will not be brought back by these means, and the disease must be treated as nervous.

Sometimes the serum flows so rapidly to the fauces and adjacent parts, in a salivation, as to deprive the patient of all power to speak; in this case, diaphoretics and laxatives, with a forbearance of all mercurials, are the speediest remedies.

APHORISMUS, (from ἀφορίζω, to separate, or distinguish). A short sentence, briefly expressing the properties of a thing; or which serves as a maxim, or principle, especially in philosophy and physic.

APHORME, (of ἀπο, from, and ὁρμη, a motive). Hippocrates expresses by this word whatever occasions a disease. It is used metaphorically, for the word relates to human actions, and their motives.

APHRÆ'NUS, (from α, neg. and φρονεω, to be wise). One who has lost the use of his reason.

APHRO'DES, (from ἀφρο, froth). SPUMOUS, or FROTHY. Hippocrates applies this word to the blood and excrements.

APHRODI'SIA, APHRODISIA'SMUS, (from Αφροδιτη, Venus). VENEREAL COMMERCE. Some express by this word the age of puberty, or the venereal age.

APHRODISIA'STICON CLI'DION, (from ἀφρος, froth). A TROCHE; so called by Galen, because it was given in dysenteries where the stools were frothy; it was used against spitting of blood and dysenteries: P. Ægineta describes it as made of balaustines, rhubarb, opium, and other astringents.

APHRODI'SIUS MO'RBUS, (from Αφροδιτη, Venus). See LUES VENEREA.

APHRODI'TARIUM. A dry powder which consisted of frankincense, scales of copper or brass, pomegranate, white lead, and starch, equal parts, according to Paulus of Ægina. Galen to a certain collyrium gave this name. Some suppose it a powder used for hollow or venereal ulcers; or to excite lust.

APHRO'GALA, (from ἀφρος, froth, and γαλα, milk). It is also called *capilactæum*, *lac spumosum*; *lactis flos*. It seems to be milk so agitated, that the whole is converted into froth. This was a remedy recommended by Galen against habitual heat of the stomach. It has been considered as similar to our cream, and by others as a SYLLABUB.

APHROLI'TRUM. See APHRONITRUM.

A'PHRON, (α, priv. and φρον, mind). From its intoxicating and narcotic quality. A wild POPPY. Also the name of a cephalic plaster described by Aetius in his Tetrabib. 4. serm. iii. cap. 13.

APHRONI'TRUM, (from ἀφρος, spume, and νιτρον, nitre, also *aphrolitrum*). SPUME of NITRE; salts formed of the vitriolic acid and calcareous earth. It is a name also of the NATRON. See ANATRON.

APHRO'SYNE, (from ἀφρων, silly,) FOLLY, or DOTAGE. See AMENTIA.

A'PHTHÆ, (from ἀπλω, to inflame). Called also, by Celsus, *ulcera serpentia oris*, SPREADING ULCERS in the MOUTH; and in England *rustula oris*, THE THRUSH; named likewise *alcola*, *lactucimina*; *vesiculæ gingivarum*; *acacos*.

Dr. Cullen ranks this genus of disease in the class *pyrexia*, and order *exanthemata*. Gen. 35.

This disorder appears in white specks upon the tongue, and the back part of the palate in children; these specks gradually spread all over the inside of the mouth, and from thence through the stomach and intestines; the size of these specks increases as the violence of other symptoms is augmented; and they are then more yellow, or of other more unfavourable colours.

Dr. Hunter thinks these white specks inflammatory exudations, and not ulcers; which seems to be

confirmed by their successively falling off, and being as often succeeded by thicker ones. Sometimes no other symptoms attend, but more frequently they are accompanied with sour belchings, gripes, diarrhœas, fever, or soreness of the mouth.

Infants are the most frequent subjects of this disorder, and those fed by the hand are more often affected than those that have the breast. In adults, they are often accompanied with miliary eruptions.

Celsus observes that aphthæ are most dangerous in infants; and Boerhaave, that in adults they are frequent in acute diseases, and are then attended with inflammation of some of the viscera. The more they spread, the danger is the greater.

In adults, the aphthæ in the mouth are distinguished from the ulcerations in the angina maligna, by the whiteness of the sloughs, by the edges not being red and inflamed, and by there not being a shining redness or rather pink colour over the fauces, with other symptoms that usually attend this species of angina.

If the cure is not soon effected in children, the contents of the bowels become more acrid, and produce vomitings, sour and curdled stools, gripings, convulsions, and often death, from the extension of the eruptions, and mortification their frequent attendant.

The stomach and bowels must be first cleared with as much of the following mixture as will operate both upward and downward.

R. Mannæ ʒ ss. aq. puræ ʒ ij. f. solutio colaturæ adde vin. antim. tartaris. gutt. xx. m. detur. cochl. medior. pro re nata.

The best topical applications are as follow :

R. Boracis opt. subtilis. pulv. ʒ i. mel Britan. ʒ i. m. f. linctus.

In severer cases, double this quantity of the borax may be added in this linctus. Whichever is used, a small tea-spoonful should be rubbed well about the mouth, once in an hour or two, and gradually swallowed. GARGARISMA ALUMINIS, *alum gargle*. In two pints of barley water dissolve two drams of alum, and three ounces of honey of roses. GARGARISMA MYRRHÆ, *myrrh gargle*. To six ounces of lime water add one ounce and a half of honey of roses, and half an ounce of tincture of myrrh. MIXTURA MYRRHÆ COMPOSITA, *compound mixture of myrrh*. To two drams of tincture of myrrh, and the same quantity of honey of roses, add one ounce and a half of lime water. All these are very proper for ulcerations in the mouth, throat, and gums; but the *alum gargle* is also serviceable in relaxations of the uvula and other cases requiring topical astringents; and the *myrrh mixture* is considered as useful for scrofulous sores, where greasy applications are inadmissible.

If after the removal of the specks the mouth is very sore, let a thin solution of the gum tragac. in rose-water be frequently held in it.

As a purge in this disorder, the ol. ricini is strongly recommended; and at the intervals of purging, much relief is obtained by giving the ipecacuanha to promote perspiration.

That severe degree of the *thrush* which is so frequent in the West Indies requires the application of perpetual blisters, which should be kept open with the ung. cantharidis, and in this case much relief is given to the patient by a due use of a proper detergent.

R. Boracis opt. subtil. pulv. ʒ ij. mel rosar. ʒ ij. acidi vitriolici diluti, ʒ ij. m. f. litus ut supra utend.

Dr. Cullen considers this complaint as associated with a synochus, and says the tongue is slightly swelled: and, as well as the fauces, is of a purplish colour; the eschars appearing first in the fauces, and at the margins of the tongue, afterwards seizing the whole internal part of the mouth, are white; and, if abraded, soon return and continue an uncertain time. There is only one which he considered idiopathic, and that is the APHTHA INFANTUM, called *lactucimen* or *milk thrush*. The rest appear to be symptomatic, and are either called *febrile*, *malignant*, *syphilitic*, *scorbutic*; and are attendant on petechial fevers. Many disputes have arisen, particularly in Germany, whether the aphthæ are in any instance idiopathic. It is useless to enlarge on this almost forgotten subject, since the disease is now admitted to have been epidemic, and sometimes infectious. We have more than once known it to be both; and, in such cases, mortification was no very unfrequent termination among young children. The best method of cure, after the evacuations, was a warm tonic plan, with wine; and, at last, considerable doses of bark were required. A gentle perspiration was kept up by such remedies as would, at the same time, support the tone and strength.

The black thrush is rare, and always a putrid symptom.

Hippocrates speaks of aphthæ of the pudenda of pregnant women, and of aphthæ of the aspera arteria.

See Celsus, Aretæus, Oribasius, Actuarius, Hoffman, Med. Rat. Syst. Boerhaave, Blackrie's Disquisition on Solvents of the Stone, Canvane's Diss. on the Ol. Palm. Christi, Hillary on the Disorders of Barbadoes, Cullen's First Lines, edit. iv. vol. ii. p. 254.

A'PHTHÆ SERPENTES. See CANCRUM ORIS.

A'PHTHOSA, APHTHOUS; belonging to aphthæ.

A'PHYA. See APUA.

A'PIASTRUM, (from *apis*, a bee). See MELISSA.

A'PINEL. A root met with in some of the American islands; it is the *aristolochia anguicida* Lin. Sp. Pl. 1362. If, with a rod, a piece of this root is put into the mouth of a serpent, the reptile, it is said, is soon destroyed. If a person chew it, and rub his hands and feet with it, the serpents shun him; nay, if he take the serpent, it cannot hurt him. The leaves and branches have a similar power in a less degree. See Hist. de l'Acad. Roy. an 1724. Jacquin's *America*.

A'PIOS. The PEAR TREE. See PYRUS.

A'PITES, or A'PITES VINUM, (from *απίτης*, the pear tree,) called also *apiites*. The WINE OF PEARS, OR PERRY. Its virtues are similar to those of cyder.

A'PIUM. It has different derivations: (from *apex*, the top, because it has a large head; from *apis*, a bee, because they use it; or from *ηπιος*, or *απιος*, mild). SMALLAGE. *Apium graveolens* Lin. Sp. Pl. 379.

The fresh roots of smallage, when produced in the native watery places, partake in some degree of the quality of henlock; have an unpleasant smell, and bitterish acrid taste; but by drying they lose the greatest part of their ill flavour, and become sweetish; they are aperient and diuretic, but the seeds are to be preferred in all medical purposes, and are good carminatives. In distillation these seeds yield an essential oil, and they

give out their virtue to spiritus vini. rect. so completely, as, on evaporation, to leave an excellent extract.

The *cicuta aquatica*, growing naturally in the same places, may be mistaken for it; but the leaves of this *cicuta* are deeply divided down to the pedicle, into three long, narrow, sharp pointed segments; but those of smallage are only slightly cut into three roundish obtuse ones.

A variety of this species is called *apium dulce*; *palustre*, *cleoselinum*, *heleoselinum*, *paludapium*, and *celeri Italorum*. By culture this plant hath been improved, and is the *celeri* of our gardens, called *APIUM SATIVUM*; in this state the roots have an agreeable warm sweetish taste, without any of the ill flavour of the original smallage: but Ray observes, that, if neglected, it degenerates into its first disagreeable state. However, as by culture and excluding the light, an operation styled blanching, or etiolation, this plant is improved for the table, it is rendered less powerful as a medicine.

The *MARSH SMALLAGE* is a larger sort, growing also in watery places, of the same nature as the *celeri*.

*A'PIUM HORTENSE*, called also *petroselinum vulg.* *apium selinum*, COMMON OR GARDEN PARSLEY. *Apium petroselinum* or *apium hortense* Lin. Sp. Pl. 379. It is too well known to need description. The roots are diuretic, and are employed in a decoction, which should be drunk plentifully. Distilled with water, a small portion of essential oil is obtained; spiritus vini rect. extracts the whole of their virtues, and after evaporation, leaves a good extract. The leaves are warmer than the roots, and afford more essential oil; but the seeds are the best part of the plant: they are warm, carminative, bitter, and diuretic. Three pounds of the seeds yield about  $\frac{3}{4}$  i. of essential oil, the most of which sinks in water. The roots are said to be aperient and diuretic, and have been employed in apozems to relieve nephritic pains and obstructions of urine. The bruised leaves have been successfully used as a discutient poultice to many tumours. Though commonly eat at table, it has been supposed in some constitutions to occasion epileptic fits, or at least aggravate them in those subject to this disease. The virtues of this plant, and the injuries supposed to result from it, are alike inconsiderable.

*A'PIUM MACEDO'NIUM*. *Petraeum*, *Petrosel.* *Macedon.* *daucus Macedon.* *patrahium*. MACEDONIAN PARSLEY. *Bubon Macedonicum* Lin. Sp. Pl. 364. We have only the seeds in the shops, which differ from the common sort in being dark coloured, and covered with a rough hoariness: their virtues are similar to, but weaker than, the common sort.

*A'PIUM MONTANUM*. See *OREOSELINUM*.

*A'PIUM PALUSTRA*. See *SIUM ANGUSTIFOLIUM*.

*A'PIUM PEREGRINUM*. See *SELINUM MONTANUM*.

*A'PIUM SYLVESTRE*. See *BUNUM*.

*A'PIUM SYLVESTRE LACTEO SUCCO TURGENS*. See *OELESNITIUM*.

*APLY'TOS*, (from  $\alpha$ , neg. and  $\piλυνω$ , to wash). UNWASHED. An epithet of wool, called by the Latins *LANA SUCCIDA*; q. v.

*APNŒ'A*, (from  $\alpha$ , non. and  $\sigmaπρω$ , *sphiro*). A defect of respiration, such as happens in a cold, &c.

*APOBA'MMA*, (from  $\alphaποβαπλω$ , *leniter intingo*). See *EMBAMMA*.

*APOBRA'SMA*, (from  $\alphaποβραζω$ , *per astum exsuo*;

*απο*, and  $\betaραζω$ , *ferveo*). The bran of wheat, or the froth of the sea.

*APOCAPNISMUS*, (from  $\alphaπο$ , and  $\kappaαπνος$ , *smoke*). FUMIGATION.

*APOCA'RSAMUM*, a poisonous drug, sometimes called *carphasum*; and its wood, which is also poisonous, *apiocarsamum*. It grows in Abyssinia, and resembles myrrh so much as to be occasionally, inadvertently, mixed with it.

*APOCATA'STASIS*, (from  $\alphaποκαθιστημι$ , to restore). An amendment, a cessation, or subsiding. In the last sense it is applied to the urine, and sometimes to tumours.

*APOCATHA'RSIS*, (from  $\alphaπο$ , and  $\kappaαθαίρω$ , *purgo*). AN EXPURGATION. A discharge downward; but sometimes employed with little discrimination to vomiting.

*APOCEACAU'LISMENON*, (from  $\alphaπο$ , and  $\kappaεαζω$ , to break, and  $\kappaαυλος$ , a stalk). It is when a bone is broken after the manner of a stalk, near the joint.

*APO'CENOS*, (from  $\alphaπο$ , and  $\kappaενουμαι$ , *evacuo*). See *ABEVACUATIO*.

*APOCENO'SES*, DISCHARGES. Applied by Dr. Cullen to discharges with blood; it is the appellation of the fourth order of the class *locales*, and implies what are styled passive hæmorrhages, in opposition to hæmorrhages with fever, included in his first class, the *pyrexia*.

*APOCERI'GMA*, (from  $\alphaπο$ , and  $\kappaηριαζω$ , to certify). A DECLARATION; such declarations as are thought proper to be made to the patient respecting his danger.

*APOCHRE'MMA*, (from  $\alphaπχρεμπω$ , to spit up). The sputum, or excretion from the bronchial glands.

*APOCHRE'MPSIS*, (from the same). Discharge of sputum,

*APOCHYLI'SMA*, (from  $\alphaπο$ , and  $\chiυλιζω$ , to extract juice from). See *SAPA*.

*APOCLA'SMA*, (from  $\alphaπο$ , and  $\kappaλαω$ , to break). See *ABDUCTIO*.

*APOCLEI'SIS*. AN EXCLUSION, (from  $\alphaποκλεισθαι$ , *aversari*). But Hippocrates uses the word, from whence it is derived, to express a loathing of food.

*APO'COPE*, (of  $\alphaπο$ , from, and  $\kappaετω$ , to cut). See *ABSCISSIO*.

*APO'CRISIS*, (from  $\alphaπο$  and  $\κρενω$ , to secrete from). See *ECCRISIS*.

*APOCRU'STICON*, (from  $\alphaποκρουω$ , to repel). An epithet for a remedy of a repelling and astringent quality.

*APOCYE'SIS*, (from  $\alphaποκνεω$ , *partio*). A BIRTH, or bringing forth of a child.

*APO'CYMA*, (from  $\alphaπο$ , and  $\chiυμα$ , a wave). The composition of wax and pitch used to preserve the ships' bottoms; and, after a long continuance in sea water, it was supposed to attain some peculiar virtue.

*APO'CYNON*, (from  $\alphaπο$ , and  $\kappaυν$ , a dog,) so called, because it was formerly worn round the neck to keep off surly dogs. A little bone in the left side of a frog, formerly held in great esteem.

*APO'CYNUM*, (from  $\alphaπο$ , and  $\kappaυν$ , a dog). DOG'S BANE, or poison for dogs. See *HIPPOMANES*, and *PERIPLOCA*.

*APOCYRTU'ME'NA*, (from  $\alphaπο$ , and  $\kappaυρτος$ , *gib-*

bous). It is spoken of tumours forming into a kind of cone, when suppurated and ready to discharge.

APODACRY'TICA, (from *απο*, signifying *negatively*, and *δακρυ*, a *tear*.) They are medicines which first excite, and then evacuate, the superfluous moisture of the eyes. Such are onions, celadine, hellebore, &c.

APODYTE'RIMUM, (from *αποδυμαι*, to *unclothe*—*απο*, and *δυω*, to *put off*.) A private room before the entrance into the baths, where the bathers undressed themselves; or the chamber where patients unclothe themselves, previous to an operation. It is also called *conisterium* and *spoliarium*.

APCE'UM (from *α*, neg. and *πιστε*, of *some quality*.) Void of all sensible qualities, possessing neither astringency, acrimony, nor any other remarkable faculty, as water amongst moist substances, and starch amongst dry. It is similar to substances, according to Galen, more nutritious than even acrimonious or bitter ones.

APOGALACTIS'MUS, (from *απο*, and *γαλακτισω*, to *abound with milk*.) See ABLACTATIO.

APOGEU'SIA, APOGEU'SIS, (from *απο* and *γεωω*, to *taste*.) See AGHEUSTIA.

APOLE'PSIS, (from *απολαμβάνομαι*, to *be suppressed*, retained, &c.); also *dialepsis interceptio*. A suppression or retention of urine, or any other natural evacuation. Hippocrates means by the term *dialepsis* the space left in a bandage for a fracture, in which the dressings are applied to wounds. The same term is applied to the extinction of the heat, and is sometimes used for catalepsy.

APOLE'XIS, (from *αποληγω*, to *cease or end*.) A decaying time of life, and opposed to the flower of age.

APOLINO'SIS, (from *απο*, and *λινον*, *flax*.) See OMOLINON.

APOLLINA'RIS, (from *απολλυμι*, to *destroy*.) See HYOSCIAMUS NIGER.

APO'LYSIS, (from *απολυω*, to *release*.) A solution, or release. Such as the exclusion of a child, the solution of a disease, or untying of a bandage.

APOMA'GMA, (from *αποματτω*, *abstergo*.) Any thing used to wipe away sordes or filth from sores, as a handkerchief, or a sponge, &c.

APOMATHE'MA, (from *απο*, neg. and *μανθάνω*, to *learn*.) Hippocrates expresses by it a forgetfulness of all that hath been learnt.

APOME'LI, (from *απο*, and *μελι*, *honey*.) A sweet liquor made with honey combs, diluted and boiled with water. Galen says, that Hippocrates, and others, called apomeli by the names of *oxyglici*, and *oxyglicum*, and that some were made with and others without vinegar: some being sweet, and others sour and sweet. It is simple oxymel.

APONENCE'MENOS, (from *απονοεω*, to *be negligent or averse*.) An adjective importing an utter aversion to any particular thing.

APONEURO'SIS, (of *απο*, from, and *νευρον*, a *nerve*.) The word *νευρον*, from whence comes the term nerve, used in its more extensive sense, means tendons and ligaments. Hippocrates, and other Greek writers, apply it in this way. The moderns use it to describe a very different substance. See NERVI. Any tendinous expansion. The tendon of a muscle, called by Hippocrates, *τεινον*, a *tendon or cord*.

These expansions of tendons, called *aponeuroses*, or

fasciæ, grow thinner till they are lost in the cellular membrane. Instances of aponeuroses are frequently met with: the outward muscles of the thigh are bound down by one of these expansions, viz. the FASCIA LATA, q. v. Dr. Hunter describes this *aponeurosis* as proceeding from the musculus fasciæ latæ, called *membranosus musculus*, on the external part of the thigh, and from the gluteus maximus on the posterior part.

The fasciæ of the legs, like those of the thighs, cover the muscles. The soles of the feet are strong fasciæ, which prevent the flexor muscles of the toes from being hurt, when we tread. The fasciæ on the thighs and legs bind down the muscles while in action, and also increase their strength by compressing them.

When matter is formed immediately under any of the fasciæ, it cannot point where it was first formed, but runs under them to some distance to gain an exit: to prevent inconveniences from this cause, as soon as matter can be felt under a fascia, it is right to give it vent immediately, and not to wait for its pointing, as in other situations; when this happens under the temporal muscle, great difficulties attend. See TEMPORALIS MUSCULUS.

APOPALLE'SIS, APOPA'LSIS, (from *αποπαλλω*, to *throw off in a hasty manner*.) An expulsion of the fœtus, as in abortions. See ABORTUS.

APOPHLEGMA'TICA, APOPHLEGMATIZANTIA, APOPHLEGMATIZONTA, (of *απο*, from, and *φλεγμα*, *phlegm*.) Medicines suited to promote a discharge of mucus or phlegm from the mouth and nose. If from the mouth, they are called *masticatories*: if from the Schneiderian membrane of the nose, *errhines*. *Pellitory of the wall*, *horse-radish*, &c. are of the former kind; and snuff, with whatever occasions an excretion of mucus, or serum from the head and parts above the throat, comes under the latter denomination. See ERRHINÆ.

APO'PHRADES, (from the singular *αποφρας*, *unfortunate*.) Those days in which an acute distemper comes to a fatal crisis, or on which there is no crisis at all, when expected.

APOPHTHA'RMA, (from *απο*, and *πθειρω*, to *corrupt*.) A medicine to procure abortion.

APO'PTHORA. AN ABORTION. (From *απορθειρω*, to *corrupt*.) See ABORTUS.

APOPHYADES. The ramification of the veins.

APOPHYAS, (of *απο*, from, and *φωω*, to *grow*.) AN APPENDIX, Any thing that proceeds from another.

APO'PHYSIS, (from *αποφύω*, to *produce*; or from *απο*, and *πύω*, to *grow*.) Any thing attached to, or growing from another, as boughs and branches: in ANATOMY it mostly signifies the projection of a bone. It is also called *appendix*, *probole*, *echphysis*, *processus*, *productio*, *projectura*, and *protuberantia*.

APO'PHYSIS MASTOIDEA, or MANILLARIS. A process of the petrous part of the temporal bone.

APO'PHYSIS GRA'CILIS. The apophysis of the neck of the malleus in the ear.

APOPLE'CTÆ, and APOPLE'CTICÆ, (from *απο*, and *πλησσω*, to *strike*.) A name of the internal jugular veins, called from their appearing full and turgid in apoplexies. See JUGULARES VENÆ.

APOPLE'CTICA. Medicines against the apoplexy, so called instead of *antihoplectica*. Vogel gives this appellation to a continued fever coming on upon an apoplexy

APOPLE'XIA, (from *αποπλησσω*, to strike or knock down, or smite suddenly). The APOPLEXY. It is called *sideratio*, *attonitus*, *stupor palperia*, *palpezia*, *gutta*; when it is slight it is called *parapoplexia*.

Dr. Cullen ranks this genus of disease in the class *neuroses*, and the order *comata*. Gen. 42; which he defines a diminution commonly of all voluntary motion, attended with sleep, more or less sound, the motion of the heart and arteries still continuing; to which may be added an oppressed respiration, and frequently a snorting. Sauvages makes fifteen species. *Nosolog. Method. Vol. II. p. 815*. Dr. Cullen reduces them to nine; *Synopsis Nosol. Meth. Vol. II. p. 183*; viz.

1st. APOPLE'XIA SANGUINEA, with signs of an universal plethora, and chiefly fulness in the head. The varieties are the *carus à frigore* and *spontaneus*; *cataphora coma*.

2d. APOPLE'XIA SEROSA, which happens generally in aged and leucophlegmatic people; *carus ab hydrocephalo*.

3d. APOPLE'XIA HYDROCEPHALICA; see HYDROCEPHALOS.

4th. APOPLE'XIA ATRABILARIA, observed in persons disposed to melancholy.

5th. APOPLE'XIA TRAUMATICA; when the head is hurt by violent external force.

6th. APOPLE'XIA VENENATA, from strong sedatives, whether externally applied, or internally taken. *Carus ab insolatione*, *carus à frigore*, &c.

7th. APOPLE'XIA MENTALIS; *carus à pathemate*, from passions of the mind.

8th. APOPLE'XIA CATALEPTICA, in which the respiration is not stertorous; and though the limbs maintain any accidental position, yet they give way to external force applied to them.

9th. APOPLE'XIA SUFFOCATA, which happens from any external suffocating power; as in cases of hanging and drowning. See SUBMERSIO, and SUFFOCATIO.

Dr. Cullen considers the *carus*, *cataphora*, *coma*, *hemorrhagia cerebri*, *cataleptis*, *cerebri affectio spasmodico-ecstatica*, and the *ecstasis*, as apoplexies; the *typhomania*, and *lethargus*, as symptomatic apoplexies. There is often also a symptomatic apoplexy from, 1. Intermittent fever. 2. Continued fever. 3. Inflammation. 4. Exanthema. 5. Hysteria. 6. Epilepsy. 7. Gout. 8. Worms. 9. Ischury. 10. Scurvy. There are also many species of asphyxy which come properly under this head. See ASPHYXIA.

To the definition of apoplexy, he adds, that the abolition of the powers of sense and motion is in some degree only; meaning, that under the title of *apoplexy* are comprehended those diseases which, as differing from it chiefly in degree, cannot, with a view either to pathology or practice, be properly distinguished from it. Such are the diseases named above. Lomnius observes, that this disorder is generally preceded by sudden and acute pains in the head, vertigo, dimness of sight, grinding the teeth during sleep, a coldness of the whole body, especially the extremities; then, as though thunder struck, the patient falls down sometimes with shrieks; immediately after the eyes are shut, a snorting comes on, the difficulty of breathing is great, endangering suffocation; the breast ceases to heave, just as if it were bound in cords; sense and voluntary motion are entirely lost.

The following species of apoplexy should be carefully distinguished, as the mode of treatment greatly differs.

The first is the SANGUINEOUS APOPLEXY, in which we find a strong full pulse, a red and bloated visage, the patient's neck swelled, an oppressed loud respiration, with a little hoarseness. This species prevails amongst the robust, who have much blood, loaded with crassamentum. The second is the SEROUS APOPLEXY, in which the symptoms are, in general, like those in the former species, except that the pulse is weaker, the countenance pale, or at least far less ruddy, and the breathing less oppressed. The third is the SPASMODIC APOPLEXY; the same signs attend this as are usual in the second species; only it is sooner removed, and rarely degenerates into a palsy. The fourth is the SYMPTOMATIC, such as from flatus in the stomach, the gout, &c.

Of the sanguinary apoplexy, the predisposing cause is a plethora, and this determined to the head by some remote cause, induces the proximate or immediate cause, a compression of the brain. Indeed the immediate cause may be brought on by different means; which, though differing in their nature, ultimately produce similar effects. The remote causes are, surfeits, indigestion, too long exposure to the sun, inordinate drinking, particularly about the age of sixty, hysteric affections, convulsions, serous collections in the brain, libidinous excess, particularly in old men, repulsion of acrid matter, suppression of urine, salivation suddenly interrupted by cold and other causes, blows and wounds of the head, poisons, noxious effluvia, or an hereditary disposition. If the causes be examined respecting their consequences, it will appear that they are either calculated to increase the volume of blood, or occasion a determination to the brain, or produce such effects there as will prevent the nerves from exercising their influence: of course they will produce apoplexy. The predisposing causes are, fulness of blood, short neck, indolence, and a lax fibre.

Dr. Cullen thinks that the proximate cause is, in general, whatever interrupts the motion of the nervous power, from the brain, or of the blood to it. In apoplexies from internal causes, he thinks the motion of the nervous power is interrupted by some compression on the origin of the nerves; and this compression is occasioned by an accumulation of blood in the vessels of the head. In apoplexies from external causes, the motion of the nervous power is interrupted by directly destroying its mobility; as when mephitic air, fumes from charcoal, &c. are admitted to the nerves. In reality, a compression of the brain from a fulness of the veins or arteries, or an immobility of the nervous power, will equally produce the disease.

From an attention to the symptoms of an apoplexy, and the appearances observed on dissecting those to whom it had proved fatal, the brain is very generally its seat. Wepfer, in his histories of those subjects, observes, that the vessels in their brains were often ruptured, or very turgid; at other times the ventricles of the brain were filled with a watery humour; or a portion of serum, or blood, was found between the brain and its membranes.

The danger seems to be chiefly proportioned to the difficulty of respiration;—if it be tolerably easy, and the patient can swallow, there are hopes; but if respiration

be very difficult, or intermittent, and what is given the patient to drink returns immediately by the nose, a recovery is hardly to be effected. Old people, worn out constitutions, and those who have been formerly attacked with apoplexy, seldom recover; but in moderately healthy persons, in the prime of life, recovery is not uncommon.

Those who have been attacked with any kind of *apoplexy* are subject to relapses, each of which is more dangerous than the preceding. Suppers, hot rooms, violent exercise, particularly in the sun, going to bed late, long sleep, continuing in the cold, especially if the feet are subject to be cold, and whatever is suspected to dispose to this disorder, must be carefully avoided.

Were the distinction of the kinds of apoplexy formerly noticed as easy in its application as it appears simple and comprehensive, the treatment of the disease might be clear and scientific. There is not a doubt of its real accuracy; but in an organ so tender as the brain, a slight compression soon destroys the minute and complicated functions for which it is designed. We thus find, and the facts will be more clear when we treat of the lesser degrees of apoplexy, particularly palsy, that the practice must soon become general and indiscriminate.

In sanguine apoplexies, in the young or robust, there can be no doubt of bleeding copiously; nor in such circumstances can any limit be offered if the remedy can be early applied, except a melioration of the symptoms. The patient should be kept in an upright position in free cold air. In fact, the disease in this state is an hæmorrhage of the brain: it however very seldom occurs except from blows on the head.

The shades between this and the serous apoplexy vary so imperceptibly, that, respecting bleeding, much must be left to the discretion of the physician. If the patient was previously of a full habit; if the remote causes have been such as very certainly to propel the blood from the extremities or surface to the head; bleeding may be admitted: yet we should hesitate in proportion to the age, the weakness, or the previous relaxed state of the patient. Topical bleeding by the cupping-glass, or by leeches, may be perhaps allowed; but in doubtful cases it is best to abstain. Bleeding in these more often injures than relieves.

The use of emetics in apoplexy has lately occasioned a warm, perhaps a disgraceful, acrimonious controversy, and it is a subject of no little difficulty. During the operation of vomiting, the vessels of the head are undoubtedly distended, and a very slight reflection would at once seemingly show that it must be injurious. On the other hand, nature appears in such circumstances anxious to excite vomiting; but the force of this argument is lessened by the reflection, that vomiting equally follows an affection of the head from external violence. It may indeed be doubted, whether, in every hæmorrhage, vomiting is not as useful by deriving to the surface, as injurious from any other effect. This consequence of vomiting we shall more fully examine in our treatment of hæmoptoe, and even mænorragia. We think it at least established, that no partial determination from the action of vomiting itself is so injurious as to counterbalance its other good effects. These are the heads of what might be easily expanded into an ample disquisition on the subject; and, in this contention

of doubts and difficulties, let us attend to experience. Vomiting, in apoplexy, has been spontaneously excited without injury. This has been evinced by frequent observation, and we can add, that, when produced artificially, as we have often seen, it has never increased the alarming symptoms. Totally independent of theoretical considerations, we consider therefore emetics as useful. Let them however be cautiously administered, and let the practitioner be decided by what he sees. If emetics are however to be exhibited, we must avail ourselves of the first moment of the patient possessing the power to swallow.

The next step, equally necessary in apoplexies of every kind, is to procure a passage through the bowels. The more violent resinous cathartics act slowly; the others require to be given in doses, which are with difficulty swallowed. An active clyster is, therefore, the first method of emptying the bowels: those who recommend lenient ones certainly never saw the disease. The remedy most easily obtained is the black soft soap, of which a full table spoonful may be dissolved in a pint and half of water. A handful of common salt may be dissolved in the same quantity of water if the soap is not at hand; or two ounces of common soap may be combined with a pint and a half of fluid. Should these not succeed, three drams of the pulp of colocynth may be boiled in a quart of water to a pint, and two ounces of common salt, with as much oil, added. When the patient can swallow, the pulv. jalapii with its tincture, and the tincture of senna, may be given in such doses as are necessary, or the patient can take.

While these measures are operating, a blister should be applied to the nape of the neck, or to the vertex, if the head is usually shaved. It has been a custom to apply with these, blisters to the legs and sinapisms to the feet, as if remedies could not be too fast accumulated. Such practice is highly injurious, for the stimulus, before the evacuation can take place, increases the disease. When the apoplexy proceeds from retrocedent gout, sinapisms to the feet are useless or dangerous: for nothing more certainly prevents a return of gout to the joints, than inflammation excited on the integuments of the part.

When these medicines have produced their effects, the practitioner should carefully watch their influence on the disease. The patient should still be kept in free cool air, and the utmost quiet should prevail around. If with this plan the complaints increase, it must be soon fatal: if it continues stationary, we may yet hope: if the patient is relieved, our hopes are more alive. In general, we would advise, after a day or two, the opening of another drain; and, at all events, the discharge from the bowels should be kept up by clysters or cathartics. Light but generous food should be taken in small quantities, and the most strict tranquillity preserved. In this way the senses gradually revive, and the returning sense should be managed with address and caution. The patient should not be acquainted with the nature of the attack; it should be considered as a transient fainting; every symptom should be represented as trifling, and no anxiety should appear on the countenances of those around. Every thing should seem to follow the course the patient was accustomed to.

The means of prevention are to keep up a drain by

a blister, an issue, or a seton near the head, to keep the bowels free, and to prevent all agitation, or every cause of irregular action of the sanguiferous system. The diet should be light and easy, but nutritious and generous, except in the more acute, sanguine apoplexies; and the bark, with valerian, we have sometimes found useful in the more irritable or the more relaxed habit.

A *coup de soleil*, of which we have some slight instances in this climate, occasionally assumes the appearance of apoplexy, but it never bears evacuations; and requires tonics, rest, and tranquillity. If this kind even arises from inflammation, the inflammatory stage is so slight and transitory that there is no time for the operation of medicines adapted to it.

Those apoplexies which arise from the diminished mobility of the nervous fluid require only active stimulants, free air, and perhaps air of greater purity. There is little room for choice in the stimulants we employ, but perhaps the Galvanic fluid will be found preferable. It follows the course of the nerves, and appears the best exciter of their activity. See GALVANISM.

The consequences of apoplexy are sometimes singular; a weakness of the mental powers in general follows, with a degree of irritability that verges on the fretfulness of childhood. The patient laughs or cries, more frequently the latter, without any adequate cause, and is amused by trifles adapted only to the inhabitants of the nursery. A singular effect is a forgetfulness of former acquired ideas, and it has happened that for years the patient has not been able to count five. These facts may admit in future of some application: it is sufficient to point them out in this place.

Dr. Flemmyng recommends trepanning as a powerful assistant in the cure of apoplexies, by taking off a degree of pressure from the brain. See his observations on this subject, in the *Med. Mus.* vol. ii. page 300, &c. Some of the *Asphixiæ* are considered as belonging to this disease. See ASPHYXIA.

Cœlius Aurelianus, Lommii Opusculum Aureum, Arætaeus, Philumenus, Galen, Paulus Ægineta, Baglivi, Boërhaave, Hoffman, Stahl. Tissot's Practical Obs. on the Apoplexy. Wallis on Disease and Health. Cullen's First Lines, vol. iii. edit. iv.

APOPLE'XIA CATALE'PTICA. See CATALEPSIS.

APOPSY'CHIA, (from *απο*, and *ψυχη*, the mind). See LIPOTHYIMIA.

APORE'XIS, (from *απο*, and *απεινω*, to stretch out). A play with balls in the gymnastic exercises.

APO'RIA, (from *α*, priv. and *πορος*, a duct). RESTLESSNESS: uneasiness occasioned by obstructed perspiration, or any stoppage of the natural secretions. See ALYSMOS.

APORRHŒ'A, (*απορροια*, *defluxus*, from *απο*, and *ρρω*, to flow from). See CONTAGIO. It means also the falling off of hair. See ALOPECIA.

APOSCEPARNI'SMUS, (from *απο*, from, and *σκηπαρνεζω*, to strike with a hatchet). A species of fracture when part of a bone is chipped off; called also *deasciatio*.

APOSCHA'SIS, APOSCHA'SMUS, (from *απο*, and *χαζω*, to scarify). See SCARIFICATIO.

APOSIT'IA, APO'SITOI, (of *απο*, from, and *σιτος*, food). A LOATHING OF FOOD. Those who are averse to food. See ANOREXIA.

APOSPA'SMA, (from *αποσπαω*, I tear off.) denotes a violent irregular fracture of a tendon, ligament, &c.

APOSPHACE'LSIS, (from *απο*, from, and *σφακελος*, a sphacelus). A mortification of the flesh in wounds or fractures caused by too tight bandage.

APOSPHA'GMA, (from *απο*, and *σφαλλω*, jugulo). According to Galen's interpretation of the sense in which Hippocrates used the term, it means the *facies* ready for straining, or after they have been strained: and, according to Pliny, it is applicable to an animal whose blood, when its throat is cut, flows into a vessel placed underneath, and by different processes is formed into food.

APOSPONGI'SMUS, (from *απο*, and *σπογγιζω*, to cleanse with a sponge). It is the using of a sponge either dry or moist for cleaning the skin, alleviating pains and itching, or for other purposes.

APOSTA'GMA, APOSTALA'GMA, (from *αποσταζω*, to distil). The sweet liquor that distils from grapes before they are pressed.

APO'STASIS, (from *αφιστημι*, to abscede). It is when a fragment of bone comes away by a fracture. It is the same as ABSCESSUS; which see. When a distemper passes off by some outlet, Hippocrates calls it an *apostasis* by excretion; when the morbid matter by its own weight falls and settles on any part, an *apostasis* by settlement; and when one disease turns to another, an *apostasis metastasis*. So Pliny calls the *apostema*.

APOSTA'XIS, (from *αποσταζω*, to distill from,) also *staxis*. Hippocrates use the word to express a small and insufficient distillation of blood from the nose. It means any distillation or defluxion of humours.

APOSTEMA, (from *αφιστημι*, to disjoin; or from *απο*, ab, and *ιστημι*, sto, to stand). See ABSCESSUS.

APOSTEMAT'IAL. Those who, from an inward abscess, void pus downwards are thus called by Arætaeus.

APOSTOLO'RUM, (from *αποστολος*, an apostle,) UNG. The APOSTLES' OINTMENT; because it is made with twelve ingredients, exclusive of the oil and vinegar; called also *dodecapharmacum*.

R. Tereb. Venet. resinæ flavæ ceræ. flav. gum. ammon. āā ʒ xiv. rad. aristol. L. gum. oliban. et bdelli āā. ʒ vi. gum. myrrh. et galban. āā. ʒ ss. gum. opoponac. ʒ iii. æruginis æris. ʒ ii. litharg. ʒ ix. ol. olivar. ℥ ii. acet. q. s. ad gummi solv.

APOSTROPHE, (from *αποστρεφω*, to turn away). Thus P. Ægineta expresses an aversion to food.

APO'SYRMA, (from *αποσυρω*, to rub off). See ABRASIO.

APOTHE'CA, (from *αποτιθημι*, to lay aside, or deposit). A shop where medicines are sold; also a GALLERY: whence APOTHECARIUS, a preparer of medicines; or, according to the present customs, the most frequent prescriber.

APOTHEG'MA, rather APOPHTHE'GMA, (from *αποθηνυμαι*, to speak eloquently). See AXIOMA.

APOTHERAPEI'A, (from *απο*, and *θεραπευω*, to cure). A PERFECT CURE; also a particular sort of exercise used for health.

APOTHERAPEU'TICA. See THERAPEUTICS.

APOTHE'RMUM, (from *απο*, and *θερμη*, heat). It is an acrimonious pickle, with mustard, vinegar, &c.

APO'THESIS, (from *αποτιθημι*, to reposit, or from

*απο*, and *τιθεμι*, to place). The reduction of a dislocated bone.

APOTHLI'MMA, (from *απο*, and *θλιβω*, to press from). The dregs, or the expressed juice of a plant.

APOTOCOS, (from *απο*, and *τιτω*, to bring forth). ABORTIVE.

APOTROPÆ'A or APOTROPAI'A, (from *αποτρεπω*, to avert). See AMULETA.

APOZE'MA, (from *αποζεω*, to boil). A DECOCTION. See COCTIO.

APO'ZYMOS, (from *απο*, and *ζυμη*, to ferment). FERMENTED.

APPARA'TUS, (from *appareo*, to appear, or be ready at hand). In SURGERY it is the collection and regular disposition of all the instruments necessary for the exercise of the art, or of any particular operation. The word is applied also to CHEMISTRY, and to any art or science where a number of instruments are necessary to be made use of, either for explaining or performing any process by way of elucidation: more generally, any arrangement for a particular purpose. Murray's *Materia Medica* is thus called '*Apparatus Medicaminum*.'

APPARA'TUS, the greater or lesser. See LITHOTOMIA.

APPENDICULA VERMIFORMIS, or CÆCI, (from *appendo*, to hang from; *vermis*, a worm; and *forma*, shape). On one side of the bottom of the cæcum lies an appendix resembling a small intestine, nearly of the same length with the cæcum, but more slender. It is so called from its resemblance to an earthworm, and its common diameter is about a quarter of an inch. By one extremity it opens into the bottom of the cæcum, the other extremity is closed. Its structure is like that of the intestines in general; and the internal coat is folliculous and reticular, like that of the duodenum. Its use is not known; it is also called *additamentum coli*, and by some *ecphyas*.

APPENDICULATUS, (from *appendo*, to hang from). In botany, it means appended to, or hanging at, the extremity. In medicine it means any thing connected.

APPE'NDIX, (from *appendo*, to hang by or to any thing). See EPIPHYSIS and APOPHYSIS. In general, parts connected with others; as Fallopian tubes are appendices of the uterus.

APPE'NSIO, (from the same). The suspension of a broken arm in a scarf.

APPETE'NTIA, APPETITUS, (from *apheto*, to desire). APPETITE. In a general sense it is an inclination towards any particular object: but in the common acceptance it is a desire of food or drink. See HUNGER and THIRST.

APPETITUS CANINUS, (from *apheto*, and *canis*, a dog). See BOULIMUS.

APPETITUS ERRONEI, and DEFICIENTES. See DYSDOREXIA.

APPLE. See MALUM and POMUM; but apple is applied to some English names, which we shall add.

APPLE, BITTER, the fruit of the COLOCYNTHIS, q. v.

APPLE, CUSTARD. See ANNONA.

APPLE, MAD and LOVE. See SOLANUM.

APPLE, OAK. An excrescence on oak trees; q. v.

APPLE, THORN. See DATURA.

APPLU'DA, (from *ab*, and *plaudo*, to beat from). The chaff of millet, panicum, and sesamum.

APPREHE'NSIO, (*ad*, and *prehendo*, to take hold of). A name of the *cataplexis*, also *antilepsis*.

APPREHENSO'RIMUM. See ANTILEPSIS.

APPROPRIA'TIO, (from *aphproprio*, to appropriate). That action of the natural heat by which the fluids are so united with the solids of our bodies as to enable them to perform their functions. Medicines are said to be *appropriated* which are adapted for a particular purpose, or directed to a particular part.

APRO'NIA, (from *απο*, and *πρων*, the top of a hill,) so called, because it grows upon mountains and wild places. See BRYONIA NIGRA.

APPROXIMA'TIO, (from *aphproximo*, to approach). A superstitious method of cure, by transplanting a disease into an animal or vegetable by immediate contact. In surgery it is applied to a fractured bone of the skull forcing its way under the sound portion, and compressing the dura mater. The overlapping of the skull of the fœtus from pressure during delivery is distinguished by the same term.

APPRO'XIS, (from *α*, priv. and *πρωξ*, a drop of water). An herb, so called by Pythagoras, which is said to take fire at a distance, like the naphtha, from its want of moisture.

APSI'NTHATUM, (from *αψινθιον*, wormwood). A sort of drink accommodated to the stomach made of wormwood.

APSY'CHIA, (from *α*, priv. and *ψυχη*, the mind). See LIPOTHYMIA.

APSY'CHTOS. A name given to some stones, which, when heated, are said never to cool again. Some of the denser stones, particularly the dark lavas and granites, certainly retain their heat a long time, and are consequently applied, when warmed, in colic pains, and to the feet. We have seen them hollowed, so as to adapt them to the convexity of the abdomen.

APSYRTO'S. A name sometimes given to the common marubium or horehound.

APTY'STOS, (from *α* neg. and *πτωω*, to spit). A denomination for disorders in which spitting, though an usual symptom, is yet wanting: some species of asthma and pleurisy are thus called *dry*.

A'PUA; called also *aphya*. The fish called *ανCHOVY*. They are taken near Genoa and Provence. When pickled, they are said to warm the stomach and to promote an appetite.

APULO'TICA. See EPULOTICA.

APUTA'SY. A tree found on the coast of Guinea, used by the natives as an antiscorbutic, and applied to the teeth and gums.

APY'ETOS, (from *α*, neg. and *πυον*, pus). An epithet for a tumour that will not suppurate.

APYRE'XIA, (from *α*, priv. and *πυρεξια*, a fever). The absence of fever; generally the interval of an intermittent.

APYRI'NA, the CURRANT VINE.

APYROME'LE, (from *α*, non, *πυρην*, nucleus, and *μηλη*, specillum). A probe without a button; a *melotris*; called also *aphronomele*.

A'PYRON, (from *α*, neg. and *πυρ*, fire). A name of SULPHUR VIVUM, because it has not felt the fire; also of the *ÆTHIOPS MINERALIS*, which see.

APYRO'THIUM, (from the same). See SULPHUR VIVUM.

AQUA, WATER; called also *alma*. This word is variously derived; some say it is *quasi a qua vivimus*, because by it we exist, others *quasi aqua* from the smoothness of its surface; some, from *αqua*, for *αqua*, *sound*, from the noise it makes in running. Natural philosophers define water to be an *insipid, ponderous, transparent, colourless, unflammable, and highly fluid* body, susceptible of the different states of aggregation from solidity to that of elastic vapour. It owes its fluidity to a certain degree of heat, since with a heat two-thirds less than that of our blood it congeals; and with somewhat more than twice the heat of our blood it boils, beyond which it cannot be made hotter.

Water is more compressible in winter than in summer, contrary to most, if not all other fluids; it is also elastic. See Philos. Trans. vol. iii. p. 640.

It is found in almost every natural body; and nature unites it with many bodies which art in vain attempts to imitate. It exists in the hardest and most compact calcareous stones, and forms the greater part of the fluids, and a considerable proportion of the solid parts, of animal bodies. It is contained in bodies either in a state of simple mixture or of combination; in the first case it renders bodies humid, is perceptible to the eye, and may be disengaged with the greatest facility; in the second its own characters disappear. In this form it exists in crystals, salts, plants, animals, &c.: water imparts to many forms of bodies hardness and transparency, particularly to salts and many stony crystals. Some bodies are indebted to water for their fixity: the acids, for instance, are supposed to acquire fixity only by combining with water. It is now however proved to be a compound body, formed by the union of oxygen and hydrogen. On this subject our readers may consult the works of modern chemists, particularly Cavendish, Lavoisier, Fourcroy, Thompson, and Chaptal, as we must consider it only in a *dietetic and medical* point of view.

Water, as it is the most ancient, so it is the best and most common fluid for drink, and ought to be esteemed the most commodious for the preservation of life and health; for not only all kinds of animals, but the greatest part of mankind, preserve life by drinking water alone. If moderately drunk it assists digestion, quenches thirst, cools the habit, dilutes the fluids, opens obstructions, dissolves viscidities, corrects acrimony, promotes the fluid secretions, and is an universal vehicle for solid food. It is superior to all other liquids, because it is purer, more simple, and more fluid than other drinks. The more pure the water the better; and that is certainly the best which falls in rain, collected from high situations in the country, then boiled a little, and afterwards distilled, the half which comes over first only to be used. This, from its purity, is also recommended to all chemists where water is to be employed; but, indeed, such as nature affords is a proper drink for mankind, if there is no impregnation to the taste or smell of a person of common sensibility. The softer and purer waters, however, are to be preferred for use; though the harder waters, or such as are impregnated with selenites, or rather earthy matters, have not been discovered by any decisive clear evidence to have produced the bad effects ascribed to them.

In the pharmaceutical use of water we must however

be more cautious. Even the purest rain water was found by Margraaf to contain a small portion of a muriated salt, and in large cities it generally contains some vitriolated salt. Distilled water should therefore be particularly employed in dissolving the pure kali, the pure ammonia, sal acetosellæ, terra ponderosa salita, argentum nitratum, mercurius nitratus, mercurius sublimatus corrosivus, and acetatus, tartarum emeticum, hepar sulphuris, and antimonii.

Water dissolves salts; and an ounce of water at a mean temperature, that of 60 degrees of Fahrenheit, will dissolve of

	oz.	dr.	gr.

Good water is known by readily mixing with soap without curdling, and by quickly boiling pease, and pulse, soft and tender; and it keeps best in large vessels, in cold places, and in earthen or glass jars.

Muddy water may be cleared by adding two or three grains of alum to each pint, and thus the water is not injured. If hard it may be rendered soft by adding a few grains of the salt of tartar to each pint, in proportion to its hardness, but it leaves a neutral scarcely less inconvenient.

River water is the best for short voyages; but the spring water is longer before it putrefies, and answers better for long ones.

Stagnant waters; water in which is much melted snow, ice, or dew; water from mines; such as rises in low flat lands, and particularly from springs which contain an unctuous or bituminous matter at the bottom; are bad: but good waters are obtained from springs which are on high lands consisting of gravel; from the clouds, by rain falling at a distance from great towns; from

rivers and rivulets: but the distilled is the most pure, and a regular drinking of it would perhaps in some cases be as beneficial as some of the most celebrated mineral waters. See Dr. F. Clifton's Translation of Hippocrates, on Air, Water, and Situation. Cullen's *Materia Medica*. Hoffman's *Systema Rationale*. Chaptal's *Chemistry*.

A'QUA MU'LSA. See HYDROMELI.

A'QUA SULPHURA'TA. See GAS SULPHURIS.

A'QUA SA'LIS. See CIRCULATUM.

AQUÆ MEDICINAE'LES, vel MINERAE'LES. MEDICINAL, or MINERAL WATERS.

Waters which contain minerals in solution are distinguished by the name mineral waters; but as there is no water found in nature, even among the purest, unimpregnated by some of these substances, the name of mineral waters ought to be confined to such as are sufficiently impregnated to produce a sensible effect on the animal economy, so as to cure or prevent the disorders to which it is liable; hence the term MEDICINAL is more applicable. They participate more or less of the matters over which they run in their subterranean passages, and from some prevailing ingredient they receive their names.

The substances which are contained in waters are either held by SUSPENSION or SOLUTION; by the first are meant *clay*, *silex*, (quartzose, vitrifiable earth,) in a state of division; *calcareous earth*; and *magnesia*. By the second, *air* of different kinds; the *carbonic acid*; *pure*, or *compound alkalis*; *lime*, *magnesia*, the *sulphates*, *muriates*, the *extractive matters* of *plants*, *hepatic gas*, &c. Silex, however, is often contained in waters, apparently dissolved by means which we cannot understand or imitate. Though the most ancient, the most general, and the most simple division of mineral waters is into cold, hot, or thermal waters, accordingly as their temperature is the same with, or exceeds that of common water.

Modern chemists of allowed abilities have arranged all mineral waters into four classes; called GASEOUS, SALINE, SULPHUREOUS, and FERRUGINOUS WATERS.

The ACIDULOUS are the most common and best known of the gaseous waters, and are those in which the carbonic acid air abounds; known by their sharp penetrating taste, the facility with which they afford bubbles by simple agitation, or even by mere standing; the property of turning the tincture of turnsole red, and precipitating lime water and liver of sulphur. These are divisible into two orders, cold and hot; the *first* comprehending cold, acidulous, and alkaline waters, such as Seltzer, St. Myon, Bard, &c.; in England, Tilbury and Clifton. The *second*, hot or thermal, acidulous, alkaline waters, as those of Mount d'Or.

This ingredient in mineral waters was first discovered in the Pymont waters by Dr. Brownrigg. There are few waters without it; but unless at least six inches of this air are found in 100 of the water, it is scarcely medicinal. The Pymont water contains from about 150 to 187 inches in 100. In general, water at the temperature of 60° can take little more than its own bulk, unless when pure alkalis, with which it can combine, be present. It is incompatible only with alkaline air.

Azote was first discovered in the Buxton waters by Dr. Pearson, and it has been suspected in the Bath waters. Dr. Garnet found it in those of Harrowgate; and Mr. Lambe (*Manchester Mem.* vol. v.) in those of Lemington Priors.

Common air was discovered by Mr. Boyle in waters of every kind, but this does not render them medicinal. Oxygen air was first discovered in water by Scheele, but has not since been found in any other instance. Indeed the medicinal waters, whose obvious qualities force them on our notice, can scarcely ever contain oxygen, since it cannot unite with water containing hepatic air or ferruginous salts. We know not that this is ever medicinal, for oxygenous air in the stomach is injurious. Hydrogenous air seems never to exist alone in water, though it may be suspected in the waters of marshes; but it is a solvent of sulphur, and, with it, forms a common ingredient in sulphureous waters. When combined to saturation it is styled by Berthollet, the *sulphurated hydrogen*; and, when united to a basis, *hydrosulphuret*. When the sulphur is in excess, it is *hydrogenated sulphur* of Berthollet; and, with a basis, *hydrogenated sulphure*; more conveniently, the *supersulphurated hydrosulphuret*. Mr. Kirwan calls these combinations, respectively, hepatic air, or super-sulphurated hydrogen, hepatules, and hepars. Of the hepatic air, water takes up about two-thirds or three-fourths of its bulk; by agitation, or heating the water, a greater quantity is absorbed. Heavy inflammable air, or carbonated hydrogen, exists seemingly in some volcanic waters, but has not been ascertained by direct experiment. Sulphureous, or vitriolic air, is also contained in the hot waters of Italy connected with volcanoes. It is apparently the excess of the vitriolic acid in the ferruginous waters, and has been usually referred to that head.

The saline waters consist of a numerous group of the acid, alkaline, earthy, and neutral saline springs. As we have just seen the excess of vitriolic acid forming its peculiar air, so the excess of the acid itself is sometimes found in the vitriolated and aluminous waters. The muriatic acid has not yet been found except in a state of combination, unless Dr. Wethering's suspicion of its existing in the waters of Nevil Holt should be realized; (*Translation of Bergman's Sciagraphia*). The boracic acid has, as we shall show, been found in some Italian lakes: in a combined state we have always received it as a natural production from the lakes of Persia and Thibet, under the name of tinkal. The nitrous acid exists only in a combined state, and we recollect of this only one instance, viz. at Bihor in Hungary. See *Annales de Chimie*, vol. i. p. 224.

Of the alkalis, the natron is most abundant in mineral waters, and it is found in an aerated state. The quantity of this salt in almost every region of the earth is considerable; and it forms a striking and convincing proof, that the waters of the ocean once covered the face of the earth; for the natron is, in almost every situation, evidently the fixed residuum of decomposed sea salt. In the natron lakes of Egypt it is accompanied with the sea salt, and the same admixture occurs in many mineral waters. Sea water has not been usually reckoned among mineral waters; it is however highly deserving of this distinction: and we cannot avoid noticing in this place a curious fact lately

published, which, if confirmed, will greatly illustrate our subject, viz. that the Galvanic spark passed through water produces an impregnation of sea salt. In the progress of our publication we shall again advert to the fact, should further experiments either confirm or oppose it. In the interval between writing and printing this paragraph, it has received additional confirmation.

The vegetable alkali is rarely found in mineral waters; yet as it has been discovered in some granites we may expect to meet with it. The solitary instances in which it has yet occurred, scarcely however support the expectation. The water at Daway in France is the only uncontroverted one which occurs to us; for Monnet's discovery of it in the waters of Aix la Chapelle has not been supported by subsequent experiments. The volatile alkali, which we should with less reason expect to find, has been discovered by Mr. Cavendish in the waters of Rathbone place in London, and by M. Malouin in France. If the kali might occur from burnt woods, the ammonia would not be a less probable impregnation from decayed animal substances.

Lime is a very common ingredient, seldom however, if ever, uncombined. Aerated lime frequently occurs, and the air in these instances acts as a solvent, and is not combined with the earth. Bergman supposes, that about 100 cubic inches of water, saturated with its own bulk of fixed air at the temperature of 50°, will dissolve nearly 29 grains of aerated lime; and about 1504 parts of fully aerated water, dissolve about one of aerated lime. Mr. Cavendish however found that this proportion was too low, and that a quarter of a grain at least might be added (Phil. Transactions, for 1767); and Berthollet has even advanced the quantity of lime dissolved in water to nearly 3 to 1500. This question is rather a chemical than a medical one, and we need not pursue it further.

Magnesia, as an ingredient in sea water, will of course appear a frequent impregnation of mineral waters. Magnesia, fully aerated, is soluble in 900 parts of water; but fully aerated water takes up a larger proportion of this earth at the period of its precipitation by a mild alkali. Of common magnesia about  $\frac{1}{300}$  is dissolved in aerated water, and by management a larger proportion. Even pure water, we are told, will dissolve  $\frac{1}{37}$  of its weight of the common earth. It is remarkable, that the impregnation of water with vitriolated kali, common salt, and Epsom salt, will render it a better menstruum of magnesia.

Argil is rather suspended than dissolved in water; but if Westrumb found nine grains in five quarts of Pyrmont water, it must have been really dissolved. We are not now speaking of aluminous waters, but of argillaceous ones, where the earth is suspended by fixed air: with its assistance, magnesia is very much more soluble than argil.

Aerated iron is very common, and 100 cubic inches of fixed air may dissolve four of iron. If in the waters of Medevi, analysed by Bergman in the first volume of his Opuscula, four grains of iron are suspended with only six cubic inches of this air, we may suspect the intervention of some other solvent.

Of all the impregnations of mineral waters, the neutral salts are the most frequent: they occur in all their varieties, and in every possible combination. The sele-

nite is a very common impregnation; and in Monro's system, compiled when chemistry had scarcely assumed a scientific form, it is called calcarous glauber. The Epsom and Glauber's salts are more rare, but frequent. Vitriolated ammonia, and vitriol of iron, are the production chiefly of volcanos. The latter occurs in the waters of Mulino near Latera (Lavoisier, Mem. de Paris, 1777); in those of Horsley Green (Garnet); and in Denmark (Bergman, vol. i. p. 176). Vitriol of copper is contained only in waters issuing from the copper mines.

We have mentioned the acid of nitre seldom occurring in a combined state; but Margraaf found some traces of nitre in the wells of Berlin, and Bergman in the waters of Nidda, near Altendorf. Nitrat of lime and magnesia occasionally occur, but these springs are not medicinal.

Of the muriats, we find muriated natron, lime, and magnesia, in many mineral springs. Muriated ammonia has occurred in some of the Italian lakes, and in Siberia (Herman, vol. ii. p. 346). Muriated barytes has been found in water by Bergman and Schoeffler; muriated argil by Withering (Translation of Bergman's Sciagraphia, p. 31); and muriated manganese by Bergman; and, in our own country, by Mr. Lambe in the water of Lemington Priors.

The sulphureous waters owe their peculiar properties to the union of alkalis or lime; but Mr. Kirwan remarks that the sulphur is never in the form of hepars, since these are always coloured, or, when diluted, become so on standing; then ceasing to have any effect on nitrated silver, lead, or any other test. Bituminated alkali occurs only in one or two solitary, perhaps doubtful instances.

Petroleum was found floating on the waters of Driburg, and in some of those of Pyrmont, by Westrumb. Vegetable and animal extractive matters are accidental, and never medicinal impregnations.

The ferruginous waters we have already mentioned: the iron is held by the sulphuric and the carbonic acid, or mechanically suspended. Of the first we have already spoken: the carbonate of iron occurs chiefly in the acidulous waters, and the mechanical suspension occurs in the forge waters sometimes used as topical astringents, to be afterwards noticed. The medicinal are, in some measure, ascertained by the *sensible qualities* of waters. To the *sight*, pure water is clear, like crystal: when less so, some heterogeneous matters are certainly present. Water that has run through a gravelly soil is generally very pure: that which has passed through argillaceous or muddy land much less so. Though good water is without colour, it does not follow that every colourless water is good. An obscure muddiness verging to yellow or red is found in stagnant waters, and may arise from the extractive vegetable matter found in marshes, or from fatty substances. A blue colour points out copper; a green, vitriol of iron. The aerial acid, when uncombined, becomes obvious by the bubbles separated on standing, or on agitation. The purest water, however, when standing *in the sun*, will discharge numerous air bubbles.

To the sense of *smelling*, good water is free from odour. When saturated with the aerial acid, it exhales a suffocating, subtle vapour. Hepatic waters resemble in smell a stale egg, or the scourings of a foul gun:

those impregnated with putrid extractive matter are distinguished by their fœtor.

Waters may be considered as pure, in proportion to their want of *taste*: even in the purest, however, the experienced water drinker will discover a difference. The aerial acid gives an agreeable pungency. Bitterness shows an impregnation of Glauber's salt, nitre, vitriolated, nitrated, or muriated magnesia, nitrated or muriated lime. Lime and selenite are distinguished by a slight austerity; alum by a little stypticity; common salt by its saline taste; alkali by its urinous flavour; copper and iron by tastes peculiarly their own, and sufficiently known.

The quantity of foreign matter in medicinal waters is ascertained by their specific gravity, compared with that of water at the same temperature. The comparison should be made with distilled water, not in small quantities, for the difference is not easily ascertained; nor in large ones, as the greater weights are not minutely exact. Vessels which hold a quart or three pints form the proper mean. The specific gravity is, however, only a test of the quantity of matter in waters without smell, for the hepatic waters are lighter than distilled. The water of Limmer and Rensdorf are instances of this kind, examined by Andria and Brockman. The lightest water is that of Envie, near Turin, eight pounds of which contain about half a grain of lime: the heaviest, that of the Dead Sea, which, according to Lavoisier, contains 44.4 per cent. of common salt, muriated lime, and magnesia, so that it is evidently a salt lake, whose fluid contents are decreasing. These extremes are 1.0000 and 1.2403. If waters abound with aerial acid, their specific gravities do not give the proportion of solid matter with any accuracy at a temperature above 50°. A convenient rule, sufficiently accurate, is given by Mr. Kirwan to ascertain the solid contents by the specific gravity, which we shall transcribe. It consists in subtracting 1000 from the given specific gravity expressed in whole numbers, and multiplying the product by 1.4. This gives the weight of the salts in their most desiccated state, but that of fixed air is also included. The fixed air should of course be previously separated, and the water of crystallisation allowed for. We shall therefore add at the end a very convenient table from Kirwan, to which we shall often have occasion to refer.

Another method of estimating the medicinal from the sensible qualities of waters, is, an examination of their *temperature*. For this purpose, it will be of use to enquire whether the temperature is the same at all seasons, whether it follows the variations of the atmosphere, or the water freezes in winter; if warm waters deposit any sediment in cooling; of what this sediment consists; and whether their sensible qualities are diminished or destroyed after the deposition.

The *situation of the waters* must not be neglected. The character and elevation of the neighbouring country; the quantity of the water, and the occasional variations in this respect; its current; the number of its springs, and the quantity they furnish; the quantity and nature of their depositions; what sublimate is observable in their channels; whether they flow tranquilly or with ebullition; what vegetables and animals they support; are circumstances of real importance in ascertaining the nature of mineral waters.

It cannot form a part of our present object to engage in details of the various methods employed in the analysis of mineral waters; yet, as the medical practitioner is sometimes called on to determine on the propriety of using any water which has not been hitherto analysed, a few short rules may not be improper or misplaced; they are not designed to obtain an accurate analysis, but to form a general idea of the nature of any water offered to observation. The description of the sensible properties of the different kinds of mineral waters will lead to a general knowledge of their contents. The acidulous waters will tinge the juice of litmus red, but the colour will disappear by exposure to the air: they will also precipitate lime from lime water, which will be again dissolved if a small quantity only is added, or if the air be in excess. If a flaccid bladder be tied round the mouth of a bottle containing the water, and heat applied, the quantity of uncombined air may be measured by the quantity in the bladder.

The hydrogenated sulphur will tarnish silver, or, more readily, lead. A mark made on paper with acetite of lead or tartrate of bismuth is instantly blackened, without producing any turbidness. A sulphuret of either fixed alkali will indeed produce the same effect, but a decomposition ensues. When the sulphur is combined with the water by means of an alkali, it may be precipitated by the sulphuric or muriatic acid, and weighed; but some sulphur will still remain suspended. Either the sulphureous acid, or the strong red nitric acid, will precipitate what is left. Oxides of lead, quicksilver, and arsenic, by uniting with the hydrogen of the gas which keeps the remaining sulphur suspended, will have the same effect. By these means we can also separate the sulphur, dissolved by means of hydrogenous gas in water.

Alkalis, when uncombined or aerated only, are discovered by changing the colour of syrup of violets green. To ascertain whether this change is owing to the fixed or volatile alkali, some muriat of quicksilver must be added. The volatile attracts a large portion of the acid, and the rest is precipitated with the metal in the form of *mercurius dulcis*.

Acids are more easily discovered. The muriated barytes is decomposed by the sulphuric acid, forming an almost insoluble compound, and all its salts are thus at once discovered: an almost imperceptible particle of either forming a precipitate. The muriatic acid can be as certainly discovered by a solution of nitrated silver with an excess of acid. Having ascertained the nature of the acid, if in the first instance an alkali is added, the lime, if the water contain a calcareous earth, is deposited; or argil, or magnesia, if these be its ingredients. If the precipitate be soluble in distilled vinegar, it is not argil; if, when dissolved, and sulphuric acid be added, no precipitation ensues, it is not calcareous, and consequently must be magnesia. The acid of sugar will at once show the existence of calcareous earth, for its attraction is very powerful and the compound insoluble.

If aerial acid be the means of the solution of the earth, it will separate in boiling; but more certainly by acetite of lead. The metal is precipitated, and the earth suspended by the acetic acid. As the lead would also be precipitated by a sulphat, a little more acid should be added, which will redissolve the lead if an

earth has occasioned the separation. The nature of the saline neutrals can only be with certainty ascertained by evaporation and the form of their crystals. If nitre be contained in water, after a considerable evaporation, the smell of the acid may be detected on the addition of some sulphuric acid.

As copper can be discovered by the taste, we need only notice the means of distinguishing iron; though this also shows strong marks of its presence by the ochery depositions on the banks of its streams and the astringency of its taste. A ready and convenient test is, however, the calcareous prussiat, prepared by boiling lime water a little while on Prussian blue: it must be kept in well stopped phials from the light. The tincture and infusion of galls are equally useful; but a little alkali must be previously added, as an excess of acid, should there be such, will prevent the change of colour. Mr. Kirwan, in his excellent treatise on mineral waters, has added a list of 'associated,' and another of 'incompatible' salts, chiefly, he remarks, for the assistance of geologists. We think a short abstract of this part of his work will be equally useful to the medical chemist. *Aerated lime* and selenite most frequently accompany each other; and *aerated magnesia* is always accompanied with aerated lime, but not *vice versa*. *Aerated soda* is generally accompanied with Glauber and common salt, but not *vice versa*. *Epsom salt* is commonly accompanied by Glauber or selenite, or both, but not *vice versa*. *Vitriol of alum and iron* are commonly associated. *Common salt*, unless with soda, is always attended with selenite; and the latter, very generally diffused, accompanies all salts except soda when in any remarkable proportion. *Muriated magnesia* is most commonly found with sea salt, but not *vice versa*, often with Epsom salt. *Muriated lime* is almost always accompanied with common salt. *Epsom and common salt* decompose each other when some degrees below the freezing point, producing Glauber and muriated magnesia; but in a higher temperature they react on each other.

Many salts found in mineral waters are *incompatible*, capable of decomposing each other; or, if simple, of decomposing some of the compound salts. This however appears to be prevented by the large proportion of the menstruum.

*Aerated alkalis* are incompatible with earthy or metallic salts; uncombined vitriolic acid with earthy nitrats, or muriats, or aerated earths; alkaline sulphats with earthy nitrats or muriats; Glauber with sylvian; vitriolated tartar with nitrated soda; vitriolated ammonia with nitre and sylvian; Epsom salt with nitrated or muriated lime; alum with nitrated or muriated lime, or magnesia; nitrated lime with sylvian, sal ammoniac, muriated barytes, or magnesia; nitrated magnesia with sylvian and muriated barytes; muriated magnesia with nitrated soda and lime.

From these few hints the nature of any mineral water may be ascertained with sufficient accuracy, and we shall now proceed with some account of the impregnations of mineral waters, and their medicinal powers. In this place it is unnecessary to be minute in giving the contents of each; it is the object of the chemist, rather than the physician. In a medical view we shall class the most noted mineral waters under their proper heads, and then consider the virtues of each class.

I. Waters with very *inconsiderable* or *no* impregnation.  
Cold. Malvern; Holywell; Plombieres.  
Warm. Bristol; Matlock; Buxton.

II. Aerial, acidulous, sparkling.

1. United with alkali: Seltzer; Clifton and Tilbury in England; Carolina in Bohemia; Mont d'Or and Bourbon L'Archambault in France.
2. United with steel: Tunbridge, Spa, Pymont, Boussan, and Pougue in France.
3. ——— Steel, hot: Bath.
4. ——— Steel and salts: Cheltenham and Scarborough.
5. ——— Hot: Vichy, Carlsbad.

III. Saline, simply with one or more neutral salts.

Sea-water; Sedlitz and Seidschutz in Bohemia; Epsom; Balaruc and Baguere in France.

IV. Sulphureous.

1. Cold: Harrowgate; Moffat.
2. Hot: Aix; Borset; Baresges and Dax in France; Baden in Germany.

V. Bituminous: Driburg, and some of the springs of Pymont.

VI. Metallic.

1. Vitriolated chalybeate: Hartfel.

It forms a problem of no little difficulty to explain, why waters with impregnations so slight and inconsiderable should ever have become famous as medicinal. It has furnished arguments for the sceptic, and refined considerations for the pathologist. If water so pure be ever useful, might we not attribute the whole to the element alone? and, having obtained this 'vantage ground,' may we not suppose that all the advantages of mineral waters are derived from dilution, added to changes of air and scene, absence from the distractions of business, or what would revive the recollection of distressing scenes or events? The argument has been drawn out with much care, decked with delusive colourings, and supported by facts, which might at least occasion hesitation. Those who have indulged in excess of every kind, in indulgences the most exhausting, would certainly be benefited by a water diet, accompanied with regular hours, with exercise in free air, with tranquillity and cheerful conversation: men, whose midnight hours have been irritated by study and anxiety, would find the surest balm in calm repose; those who have never sought rest, but in fevers from wine, and 'rude wasseling,' must feel peculiar comfort in the calm of temperance and cheerfulness: men who have burnt under the torrid zone, and whose fluids are highly animalized by scorching heat, will find the cooling streams soothing and salutary. These representations may be allowed, yet they will not prove all that they are designed to show. Crowds of hectic patients seek, and often seek in vain, relief in the pure springs of Bristol; yet, had they not been advantageous, crowds would never have resorted to them. Pathology steps in to our aid, and attempts to show that medicines in a form highly attenuated may produce effects to which in a grosser state they were unequal; that the peculiar appropriate effects of every medicine are attained only in a suitable dose; and that, beyond this, each is indiscriminately stimulant. To reasonings of this kind, on either side, we need no reply; but we must have recourse to experience, which

tells us, in language not to be misunderstood, that waters of a given class are highly efficacious in their appropriate diseases, let the immediate cause be what it may. If we were to give our own opinion, it would be limited and discriminated. We see striking effects of acidulous, of sulphurated, of saline, and chalybeate waters; but for this reason, must we deny them to the purer kinds? We know that the effects we perceive are not in proportion to the doses of the active ingredient swallowed; may we not then suppose, that ingredients apparently less active may have effect in the same form? In reality, we would not give them all the merit assigned, or deny wholly their powers. We believe the purest waters have been useful; and are convinced that those which possess the more active ingredients, have been highly salutary.

This disquisition we have been led into from the first class of waters; and we may now add, that chemistry may probably detect ingredients not yet suspected in some of these, as azotic gas appears to have been found in those of Buxton; and perhaps oxygen may occur in others, as it has been suspected in the waters of Plombières. The second class, the *acidulous waters*, stimulate the stomach and improve the appetite. They are certainly refrigerant and antiseptic: refrigerants we shall find to be deobstruent, and, in some constitutions, diuretic. Perhaps the acidulous waters are adapted to those who have injured the stomach by excess in drinking: when joined with chalybeates, this advantage is more strikingly conspicuous. If ever these waters prove peculiarly useful as deobstruents, it is when they are united with neutral salts; but to follow this subject would be to anticipate what more naturally occurs under the next head.

The saline waters are certainly cathartic and diuretic: they have the credit of being alterants and deobstruents. Of the supposed acrimonies of the fluids we have already spoken, (see ALTERANTS,) and have remarked, that though what appears in excrementitious fluids must have existed in the blood, yet it never formally appears in that fluid. We may now add, that such is the connection between the secretory organs, that a derivation from one of these will prevent a deposition on some others. Thus the discharge of the more fluid secretions from the bowels will check similar ones of the saliva and of the skin; and to cure, or certainly to prevent, the recurrence of cutaneous eruptions, there is no more certain remedy than the saline mineral waters, particularly sea water. Obstructions of greater consequence occur in the chylopoietic viscera and the conglobate glands. Dissection shows us that the liver, the pancreas, and other organs of the abdomen, may be obstructed, enlarged, become scirrhus, or otherwise diseased. For these complaints the saline mineral waters are recommended with advantage. To explain their effects we must first notice the general principle previously alluded to, that the chief and first effect of all deobstruents is refrigerant or sedative. When obstruction exists, if the circulation is accelerated and the obstacle is not conquered, the matter must be more firmly impacted; and at a distance from the source of power, the action of the vessels must be comparatively weak and inconsiderable. To this we know but of one exception, viz. the action of mercurials, whose stimulant power is chiefly felt in the extreme vessels. In-

dependent, however, of the refrigerant effect of saline medicinal waters, they generally increase the discharge from the excretory ducts of the obstructed part, and of course relieve the over distended vessels; not only preventing further impaction, but taking away the impediments to the action of arteries already obstructed.

The action of these waters on obstructions of the lymphatic glands we have also already glanced at. It was the language of Dr. Cullen that saline waters, particularly sea water, 'washed out' the lymphatic system. We know not, however, by what channels they could reach glands whose disease consisted in refusing a passage to every absorbed fluid; and when we before noticed this effect, and was willing to attribute it to the power which salts possess of rendering the gluten more fluid, we were obliged to allow that the matter of scrofulous glands was not gluten. Saline waters are, however, very valuable remedies in these complaints; and they seem useful by increasing the action of the lymphatic system, which is probably in this disease defective. Obstructions of the mesenteric glands are very often relieved by saline waters; and from what we have observed of their powers, it will be easy to see on what principle their good effects depend. In some late authors, the *physconia abdominalis* is mentioned among the diseases to which these waters are adapted. The complaint consists in hardened tumours in the abdomen, apparently not connected with glands of either system; and if the remedy is useful, we must confess our ignorance of its manner of acting.

Some of these saline waters are recommended in cases where we hesitate respecting their power, or the means, if their efficacy be admitted, by which they relieve. We allude to those cases of exhausted constitutions which are supposed to find relief from Cheltenham. It is said that the chalybeate impregnation obviates the debilitating power of the cathartic salts. In fact, we strongly suspect that in all such cases an obstruction of the liver has occasioned or coincided with the other complaints, and that the relief obtained has followed from the effects of the waters formerly mentioned. It is contended, however, that they are useful in other circumstances, and we cannot deny that they have appeared to be so; but with the little experience we at a distance can possess, it would be the height of arrogance to contend against the enlarged field of observation a residence on the spot affords.

Melancholy and dropsy, two diseases, for which the saline waters are recommended, need not detain us: in each there are generally obstructions in the viscera, and in each gentle laxatives are useful.

The aerated alkaline waters are now peculiarly fashionable, and the *artificial* soda water, which we shall mention in another article, is frequently drunk: it is recommended as a stimulant, a tonic, a solvent, and a stomachic. In weak digestions, in gouty apespsia, in stomachs abounding with acid, it is highly commended, and is not without its merit, though the *popularis aura* seem to have extolled it beyond its bearing. In nephritic and calculous complaints it is recommended as a solvent; but it is doubtful whether its power is obvious in any other organ except the stomach. The acid evolved in the urea, in the perspiration and calculi of arthritic patients, is apparently generated in the stomach, and is there counteracted by antacids. If, how-

ever the alkali can be conveyed without change to the bladder, it may certainly be useful as a solvent. In inflammatory fevers it acts as a cooling laxative, and in some cases of hectic appears beneficial; but, as a remedy in putrid fevers, this gas is too trifling as an antiseptic to detain us a moment.

The sulphurous waters are very powerful and active remedies; as the sulphur, in the attenuated form which it assumes in its combination with inflammable air, is conveyed to the smallest vessels. These waters have been long employed in diseases of the skin; and, as they are used both externally and internally, they produce very considerable effects. In gouty swellings and diseased joints from this and other causes, the warm sulphureous waters are highly useful; in the chronic pains from gout, rheumatism, contractions, or indeed any cause, they afford considerable relief. They are supposed particularly effectual in diseases produced by arsenic, lead, or mercury: but we suspect that this opinion rather arises from the power of sulphur on metals out of the body, than from actual observation. In such diseases, the metal seems to be soon discharged out of the system, and the effects only remain.

Modern refinement, perhaps modern theory, has added another group of complaints to those which are likely to be benefited by sulphureous waters, viz. the diseases arising from too great a proportion of oxygen in the system. Pathologists have not traced this cause very extensively; but it has been supposed to occasion the diabetes mellitus, and in hectic the florid blood seems to show that the fluids are highly oxygenated. In the former, Dr. Rollo advised the hepatised ammonia; and other authors have thought that the same object might be more conveniently attained by these waters. We know not that they have been employed in hectic, but air of a lower quality than that of the atmosphere seems occasionally useful; and we strongly suspect that the credit of the Bristol waters has been lessened, since it has been fashionable to reside nearer the summit of the hill.

Of the bituminous waters we have had little experience, and need not enlarge. We perceive in some authors, that water impregnated with what is called fossil oil occur in this kingdom and in different parts of the continent. In our own country the waters of Brosely, Pitchford, and Wigan, are enumerated; in France, those of Gabian and Plombieres; in Germany, that of Waldsborn. In fact, the accuracy of modern chemistry has not yet sufficiently illustrated the nature of several mineral springs; nor are the medical reports wholly free from suspicion of superstitious, prejudiced, or interested exaggeration. We have, consequently, preferred giving the general outlines of the analysis, with the knowledge to be drawn from the sensible qualities of the water respecting its ingredients, to the list of mineral waters, with which we had purposed to conclude the present article.

The metallic impregnations only remain, and under this head we purpose to speak more particularly of the Bath waters. These springs have been long and highly esteemed; but the chemist has been disappointed in finding so little foundation from his analysis for the character they have for so many centuries enjoyed. This water consequently furnishes a strong argument in favour of those who consider the attenuated form of the impregnation as the chief source of the benefit arising from it. Simple warm water has indeed been substi-

tuted, and many are the virtues attributed to it in assisting digestion. Such it may possess; but till it produces all the varied effects of the Bath waters, we shall have little confidence in the refinement. Every physician, who wishes to distinguish himself at Bath, writes on its waters, and endeavours to add to the stock; yet we are still little acquainted with the volatile ingredients which occasionally produce giddiness, and, when improperly used, fever. It is not very unreasonable to presume that it is inflammable or azotic gas. The iron is in a small proportion; and a late author, who has plumed himself on the discovery of silex in this water, has advanced very little in the discovery of the cause of its powerful effects. Bath waters are certainly warm and tonic: in the arthritic weakness of the stomach they are highly useful; in palsy, if the effects of the stimulating, inebriating principle be avoided, they are very serviceable; in topical weaknesses of the joints they excel almost every other remedy. In the relaxation of the hip joint, we perceive, from the records of the Bath hospital, they have given important relief: in chronic obstructions of the viscera they are equally valuable.

The waters impregnated with vitriolated iron only are more simply tonic; and the forge water, where the iron seems only mechanically mixed, is chiefly useful as a topical application.

The other metallic impregnations of water are copper, arsenic, and tin: of the two latter however we have no proofs, and we think they have never been discovered. Copper in water chiefly occurs near mines; but we perceive in Ireland the mineral waters at Balle-murtoch and Cronebaum accounted cupreous; and those of Altenburgh, Cement, Goslar, Herengrunde, Neusol, and Schmelnitze, in Germany, are supposed to be of a similar nature. They are used only as topical applications to old ulcers, and sometimes in chronic ophthalmia.

We may perhaps be accused of neglect, for not more particularly noticing the cretaceous waters and the sea water. Of the former, Bristol waters are a striking and an almost solitary example; nor are we ignorant of different effects supposed to result from its demulcent properties, particularly in hectic and diseases of the bladder. It is sufficient to mention them in this place for the use of those who have more credulity on these subjects than ourselves. We see no other effects from these waters than from a mild pure fluid, which is certainly useful, though not the only source of the advantages which mineral waters impart. The Bristol springs have been thought serviceable in diabetes: a fact that requires a more ample consideration of the disease than can be admitted in this place.

Sea water has been supposed to possess peculiar power; but if more eminently useful than other saline purgative waters, the advantages chiefly result from its being more easily procured and longer continued. Yet we must remark that common salt is a necessary condiment to many tribes of animals. To man it is equally of importance, since it furnishes the most common and salutary stimulus, so that we may suppose it peculiarly advantageous in diseases. In fact, we find it so; and, where the constitution can bear its action, which is not always mild, it is highly useful. Physicians have supposed that it owes some of its advantages to the bittern, the oily matter which it contains. This cannot

be denied, though it is not probable. Yet when we reflect that the salts of marine plants and of other marine productions are often particularly useful as deobstruents, more so than even the salt itself, we must not deny some peculiar advantages to their pabulum.

The administration of these remedies requires but little particular attention; the doses of the saline waters must be regulated by their effects. They should be drunk till they produce a slight evacuation from the bowels; and, of course, the weaker impregnations are of little importance. If a pint, or from a pint to a pint and half daily, does not produce some sensible effect, the quantity of fluid will be more injurious as a load, than useful as a medicine. The chalybeate waters, if also saline, should produce some sensible effect in the same way; and, it is said, that the tonic power of the metal prevents their debilitating effects as cathartics. The sulphureous waters have, in general, their appropriate doses regulated by their other impregnations. Those wholly chalybeate must never be drunk in large quantities at once, or without some preparation. The quantities of the Bath waters necessary for different diseases are taught on the spot: it is a sacred science which the uninitiated must not aspire to know: *juvat integros accedere fontes, atque haurire*. The others require no particular advice, except not to distend the stomach so far as to produce inconvenience. This caution is peculiarly necessary in the use of the acidulous waters. In general, it is better to begin with small quantities, and repeat them often. If sea water is too nauseous, or excites too much thirst, a portion of milk added to it will greatly diminish the inconveniences.

See Kirwan and Sanders on Mineral Waters, Monro on Mineral Waters, Falconer on Bath Waters, Monnett's Hydrologia, Annales de Chimie; Fourcroy's Connoissances Chimiques.

**A'QUE MINERALES ARTIFICIALES.** The preparation of artificial mineral waters has now almost become a science. Since the idea is in a great measure abandoned, that in the vast laboratory of nature they can be only with advantage prepared, many have attempted to imitate them by impregnating common water with their contents. We have just now admitted that the ingredients are of consequence as medicines, but have at the same time allowed that many of the effects are owing to a change of scene, of air, and of habits. We cannot therefore expect from these creatures of art what we find from the natural waters, assisted as they are by the other advantages; at the same time, it is of importance to consider the progress and state of this very useful art, which will supply in part the advantages derived from visiting the springs. It has been common to attribute the invention to Dr. Priestley. In fact, we are indebted for it to a French physician of Montpelier, who, in 1755, presented to the Academy of Sciences an account of his method of imitating the Seltzer waters. Bergman, in 1774, followed these steps; and, in his successive dissertations, published in 1774, 1775, and 1778, taught us to prepare the waters of Seidchut, Seltzer, Spa, and Pyrmont; the cold and warm hepatic waters. In this interval, Dr. Priestley gave us the form of preparing the acidulous waters; and Mr. Lane taught us that water thus impregnated was a menstruum of iron. In 1779, M. Duchanoy, a French chemist, reduced the scattered facts to a systematic

form, but added little to them. He was followed by numerous other instructors, till M. Paul of Geneva, and M. Schweppe in this country, have rendered the art an almost perfect imitation of nature. Imitation! it is more, for all the noted waters are prepared with an accuracy which prevents their being distinguished from those which nature offers in stronger or weaker states, and with additions adapted to the disease. M. Paul, it is said, has sold 40,000 bottles of artificial Seltzer water in one year. Of M. Schweppe's manufacture we have received no information, so that our account of this list must be collected from the report of the French academicians appointed to examine M. Paul's apparatus and management. The general doctrines we have anticipated in the article of MINERAL WATERS, and the impregnations are those which the most accurate analysis has detected in the natural mineral waters. When the acidulous waters are prepared by the separation of the carbonic acid gas from chalk or marble, some of the vitriolic acid escapes with the air, and gives a harshness not found in the natural acidulous waters. M. Paul prepares it with carbonic acid gas, separated by combustion, and all the airs are united to water by compression. His alkaline water is prepared with potash, in compliance with the directions of Mr. Home and others, who have recommended it in calculous cases. In the natural waters, however, the alkali is the soda; and this is the salt in the Vichy waters, and many of those of Puy de Dôme, and Mont d'Or. In many of his aerial waters, the quantity of air is greater than in the natural waters: experience must determine whether this is an advantage, for we know that we lose the peculiar qualities of a medicine by excess in the dose. It is evident, however, that the unavoidable loss in keeping, in uncorking, and pouring out the water, is thus compensated. The sulphureous waters contain half their bulk of pure hydrogenated gas, with  $\frac{1}{32}$ , or, in the stronger kind, one-fourth of the sulphureous hydrogenated gas. According to Bergman, the proportion of the latter ingredient is larger. An alkali with an excess of carbone has been lately offered to sale, to prepare the aerial water extemporaneously. Air rapidly escapes in solution; but, to make the salt efficacious, it should be dissolved in a close vessel, or drunk during the solution.

The oxygenated water is a new remedy, yet it seems rather *pressed into* the water than united with it, and very readily escapes. It should certainly be drunk from a siphon, furnished with an accurately ground stop cock. Of this remedy we have no experience; yet, in the Bibliotheque Britannique, a work of character and credit, we find many facts in its favour. It seems from this work that the oxygenated water may supply the use of acids, and of various oxygenating remedies; but we would recommend its being used with caution, as oxygen in the stomach appears to be occasionally injurious. The oxygenated water has no taste, while the oxygenated wine, a quack medicine recommended in fevers, is slightly acid, and certainly consists only of wine with a small proportion of one of the mineral acids.

The hydrogenated and hydrocarbonated waters contain, respectively, half their bulk of air. Of these little use seems to have been made, and the trials hitherto have spoken little in their favour.

As the artificial mineral waters are becoming fashionable, we shall add a table of the solubility of the different gases in one hundred parts of water.

Muriatic acid . . . . .	100
Alkaline air . . . . .	34
Sulphureous acid gas . . . . .	3.96
Nitrous oxide . . . . .	0.27
Carbonic acid . . . . .	0.17
Nitric oxide . . . . .	0.16

*AQUÆ THERMALES.* The warm mineral waters distinguished by this title we have in general noticed in a preceding article; and it is now only necessary to consider the peculiar advantages derived from their heat. Were our present object chemistry in general, we might examine at some length the cause of this heat, which has been hastily and indiscriminately said to be subterraneous fire. The problem was thus quickly dismissed; and little enquiry into the probability of volcanic fires existing in the spot where these warm waters were found was thought necessary, and less investigation into the cause of these fires continuing to burn for

ages with a temperature neither increased nor diminished. There is little doubt of the heat being derived from decomposition, and in general of martial pyrites. These contain a large proportion of caloric; are found in vast extensive beds; and, when decomposed, may for ages continue to give out and communicate heat of a steady temperature. In general, they add greatly to the effects of the sulphureous waters, and often to the chalybeate. For external use they are in general preferable; and when percussion is added by pumping or pouring the water from a height, their stimulant and tonic effects are greatly increased. In these ways the waters of Bath are so singularly useful. This subject must, however, be resumed, when we consider the importance of bathing in general; and we shall then add what seems to render the Bath waters in this form so frequently of peculiar value as a remedy. The heat of thermal waters differs from 92° to 212 of Fahrenheit. See *BALNEUM*, and *BATHING*. We shall add the table formerly alluded to.

Of the Proportion of Ingredients in the following Saline Compounds.

100 parts <i>Carbonic.</i>	Basis.	Acid.	Water.	State.
Aerated Tartarin - - - - -	41, - - - - -	43, - - - - -	16, - - - - -	Crystallized.
Common Salt of Tartarin or Pearl ash	60, - - - - -	30, - - - - -	6, - - - - -	Dry.

A'QUE PA'VOR, (from *haveo*, to fear). See HYDROPHOBIA.

A'QUE STILLATI'VE SIMPLICES. The SIMPLE DISTILLED WATERS, now called only *aque*; the word simplex is omitted.

Distilled waters are only water impregnated with the essential oil of the subjects distilled with them. When more oil is brought over than the water can take up, it swims at the top, or sinks to the bottom, and is to be separated by a funnel. Cohobating may answer for obtaining more essential oil, but it does not increase the strength of the water first distilled; and such plants as do not sufficiently impregnate the water at the first distilling are improper subjects for this operation: other methods are to be used to obtain their virtues. See DISTILLATIO.

Distilled waters are extemporaneously made with the oleo-sacchara, oils rendered miscible with water by rubbing them with sugar, or with the essential salts. See OLEO SACCHARUM.

When simple waters are used alone, or as the principal medicine, they are not disagreeable; but when used only as vehicles for other more powerful remedies, distilled water is by far more elegant; and as but few of the simple waters are of sufficient efficacy to be used alone, they are hardly worth the trouble of making.

A'QUE STILLATI'VE SPIRITUOSÆ. SPIRITUOUS DISTILLED WATERS, now called only spiritus, viz. *spiritus pulegii*, &c.

All the virtues of distilled waters are owing to the essential oil they take up. Spirit of wine differs from water in keeping all the oil that rises with it perfectly dissolved in a limpid state: but yet as spirit of wine boils in about one-fifth less heat than water, it is an improper vehicle for substances that require the heat of boiling water. Thus, in distilling cinnamon with a proof spirit, the spirit rises with very little flavour of the cinnamon; but when the water follows, it brings with it the oil of the spice. Various essential oils are in this way combined with spirit of wine, and sold as

secret preparations, and under delusive titles. The *essence of peppermint* is of the former kind; and the *essence of mustard*, which consists almost wholly of oil of turpentine distilled with spirit of wine, is an instance of the latter.

Distilled spirituous waters are of the strength of proof spirit, and formerly were called compound waters, in contradistinction to those that consist only of simple or common water. The most agreeable spirituous waters are made by using a pure rectified spirit of wine, covered with a proper quantity of pure water.

When the distilled liquor is as strong as rectified spirit of wine, it is called distilled spirit. See CARMES, EAU DE.

The distilled waters formerly employed were very numerous, though attended with no real advantage: we still retain too many. The water of dill, that of *cinnamon*, fennel, *peppermint*, spearmint, *allsage*, pennyroyal, *rose leaves*, *lemon peel*, Seville orange peel, and cassia, still overload our Dispensatories; and those marked with italics afford a very ample supply.

The spirits of modern dispensatories were the spirituous waters of the former. We shall shortly mention them in this place, but return to them afterwards. Those retained by the London college are the spirits of caraway, of cinnamon, peppermint, spearmint, nutmeg, pimento, lavender, rosemary, compound spirit of aniseed, juniper, and horse-radish.

Some spirituous waters have survived the rage of reformation, and still retain some credit. AQUA EPIDEMICA consists of the roots of imperatoria, with the seeds of angelica, and the flowers of elder, distilled from French brandy. HUNGARY WATER is the spirit of rosemary. AQUA ODORIFERA, honey water, is prepared from honey, coriander seeds, vanillos, cloves, nutmegs, lemon peel, storax, and benzoin, distilled from spirit of wine, previously adding spirit of roses and orange flower water. The AQUA VULNERATA, *arquebusade* water, is prepared from numerous aromatics, as thyme, balm, rosemary, &c. few preparing it exactly in the

same way. They are spirituous and stimulant; used often as perfumes; and too often, we fear, as medicinal drams.

Modern nomenclatures give also the name of waters to solutions of salts, saline earths, and metallic neutrals. Thus we have *aqua aluminis composita*, formerly *bateana*, consisting of two drams of alum, with as much zinc, to a pint of water; *aqua cupri ammoniata*, which is a solution of a dram of muriated ammonia, in a pint of lime water, suffered to stand in a copper vessel till it assumes a blue colour; *aqua lithargyri composita*, which contains a dram of aqua lithargyri, with as much spirit of wine, in a pint of distilled water, as will render common water turbid; *aqua zinci vitriolati cum camphora*, which consists of a quart of distilled water, with half an ounce of vitriolated zinc, and as much camphorated spirit of wine, but the camphor is precipitated, and its smell only remains.

The other solutions styled waters are, *aqua calcis*, *aq. kali puri* and *preparati*, *aq. ammoniæ*, *ammonie pure* and *acetate*, and *aqua phagedenica*, which is a solution of half a dram of corrosive sublimate in a pint of lime water.

AQUÆDU'CUS, FALLOPII, AQUÆDU'CTUS, (from *aqua*, water, and *duco*, to draw). See TUBA EUSTACHIANA.

A'QUALA. See ARSENIUM, and SULPHUR.

AQUALI'CULUS, AQUALI'CUS, (from *aqualis*, a water pot). That part of the belly from the navel to the pubes, being considered as a cistern and container of the excrements. Sometimes it is used to express the stomach or the intestines. It is the same with HYPOGASTRIUM.

AQUARIUS. See FERRUM.

AQUA'TUM, (from *aqua*, water,) vel AQUEUM, WATERY, DILUTED. Also the *chalaza* of an egg. See CHALAZA.

A'QUETTA, a name of the famous secret Italian poison, called also *aqua tophania* and *aqua della toffana*. Its ingredients may be easily guessed at from the accounts which have been transmitted to us, but we think we should do little service to society or humanity by recording the means of committing such secret villainies.

AQUIDU'CUS, (from *aqua*, and *duco*, to draw). See HYDRAGOGOS.

AQUIFOLIUM, (of *avis*, a prickle, and *folium*, a leaf). It is also called *agrifolium*, *ilex aculeata bacifera*, HULVER TREE, HOLM, or COMMON HOLLY. *Ilex aquifolium* Lin. Sp. Pl. 181. It is a prickly bush, commonly known. Its bark is used for making BIRD-LINE, which is also made of *misleto* and several other vegetable matters. The berries of the holly are warm; ten or twelve of them discharge wind and slime by stool.

AQUILA, is a chemical name for *sal ammoniac*. Paracelsus uses this word for *mercurius præcipitatus*; and it is a name for arsenic, for sulphur, and for the philosopher's stone.

A'QUILA A'LBA, a name of calomel and sublimate, &c.

A'QUILA A'LBA PHILOSOPHO'RUM, et GANYME'DIS. See AMMONIACI SALIS FLORES.

A'QUILA CÆLESTIS. It is the panacea, or cure for all diseases. It is a preparation of mercury.

A'QUILA VE'NERIS. A preparation made with verdigrise and sublimed sal ammoniac.

A'QUILA hath many other epithets joined with it, as *rubra*, *salutifera*, *volans*, &c.

A'QUILÆ, (from *aquila*, an eagle). The veins which pass through the temples into the head, which are particularly prominent in the eagle.

A'QUILÆ LIGNUM. EAGLE WOOD. It is generally sold for the agallochum. It is that part which is next to the bark.

AQUILO'NES, (from *aquila*, an eagle, from their rapid motion like that of an eagle). North-east winds. See ETESIÆ.

AQUO'SUS HU'MOR O'CULI. The WATERY HUMOUR of the EYE is a limpid water that fills all the space between the cornea of the eye, and the anterior part of the crystalline humour. This space is divided into the anterior and posterior chambers; the first and larger division is betwixt the cornea and the iris. The second is betwixt the iris and the crystalline humour. The vessels which furnish this fluid are too small to be described. If discharged by a wound, it is restored in two or three days. In old age it is not so limpid, and this is one cause of obscure sight. The chief uses of it seem to be to distend the cornea, so that the rays of light may be duly refracted in passing to the retina; and for the iris to float loosely in, whereby its actions may be easily performed. It has been supposed to be much lighter than distilled water; but M. Chevenix found its specific gravity to be 10053. In the eyes of sheep the aqueous humour is 10090, and it contains, in very minute proportions, albumen, gelatine, and muriat of soda. See OCLUS.

A'QUULA. A small quantity of limpid water. The term is applied to the pellucid water which distends the capsule of the crystalline lens, and the lens itself; and to a disorder of the eye lids. P. Ægineta, in lib. vi. cap. xiv. says, that it is a pinguinous substance under the skin of the eye lid, also called *hydatids*. It is the *hordeolum hydatidosum* of Sauvages; *hydatidous*, or WATERY STIAN. In children it is sometimes so troublesome as to produce much uneasiness. The upper eye lid appears watery, and cannot be elevated; the eyes are very tender, distilling a fluid, especially in a morning, if exposed to the light. In order to the cure, an incision is made through the skin of the eye lid, and the cyst is to be dissected out, if it cannot be eradicated by gently pulling it.

Mr. St. Yves takes notice of a complaint on the edge of the eye lids, or on the tunica conjunctiva, which resembles the bladders that appear on the skin after a burn; he calls these also *hydatids*. The method of cure which he proposes, is to open the tumour with the point of a lancet. But if all the circumference of the globe is covered with water, the conjunctiva will be inflamed; and in this case bleeding, purging, and a collyrium of aq. calcis, will be necessary. See Wallis's Nos. Meth. Oculor. Bell's Surgery, vol. i. p. 264.

A'RA PA'RVA, (from *arisa*, to raise up). A LITTLE ALTAR. A neat way of applying a bandage, so as to resemble the corner of an altar.

ARA'BICUM, GUMMI. See GUMMI ARABICUM.

A'RAC. (Indian.) This is an Indian spirituous liquor, prepared in many ways, often from rice; (see ORYZA;)

sometimes from sugar fermented with the juice of cacao nuts; frequently from toddy, the juice which flows from the cacao nut tree by incision. The Tun-gusi, a race of Tartars, prepare it from mare's milk. In general, arac is hot and heady, occasioning great uneasiness in the head and stomach: in other respects it resembles ardent spirits.

We find also that it has been prepared from the American maple juice.

A'RACALAN. See AMULETA.

A'RACA MIRI. (Indian). A shrub growing in Brasil. It bears fruit in March and September, which tastes like a mixture of musk and strawberries; and when candied or made into a marmalade, is cooling and moderately astringent. The leaves and buds have the same qualities, and the root is diuretic and antidy-senteric. Raii Hist. The plant has not been systematically ascertained.

ARA'CHNE, (from *arag*, Hebrew, *to weave*). See ARANEA.

ARACHNOI'DES, (from *αραχνη*, a spider, and *ειδος*, a form). See ARANEA, and PIA MATER.

A'RACON. See ÆSECAVUM, under Æs.

A'RACUS AROMATICUS. See VANILLA.

A'RADOS, (from *απαειω*, to be turbulent). Hippocrates means by it the perturbation excited in the stomach by digestion. It also signifies any perturbation in the body.

ARÆ'ON, (from *αραιος*, rare). Thin, rare, slow. It is applied to breathing, as when we say the breathing is not frequent nor thick. The air is also said to be rare, when not too much condensed.

ARÆO'TICA, (from *αραιος*, to rarify). Things or medicines which rarify.

ARA'LDA. See DIGITALIS.

ARA'LIA, (from *ara*, a bank in the sea; so called because it grows upon banks near the sea). BERRY-BEARING ANGELICA, or ANGELICA TREE. The flowers consist of many leaves, which expand like a rose and are naked, growing on the top of an ovary. These flowers are succeeded by a globular fruit, which is succulent and full of oblong seeds. It is the *aralia racemosa* Lin. Sp. Pl. 393. In its natural order it has been usually arranged among the *umbellifera*, but Ventenat has separated it, and formed a new order from this genus, the *araliaceæ*. The *a. undica'talis* grows in Canada, and is there called *sarsaparilla*, because its roots and virtues are nearly the same. See Miller's Dict. and Philos. Trans. Ab. vol. v. The *a. octophylla* and *palmeta* grow in China, and their bark is supposed to be useful in dropsies.

ARA'LIA HU'MILIS. See GENSING.

ARA'NEA, (from *αραω*, to knit together,) called also *arachne araneus*, the CATCHER, the WOLF, and SPIDER.

Spiders are absurdly said to abound with volatile salt, in consequence of which they are sometimes useful in agues, if taken inwardly. A scruple of the spider's web, it has been said, in many instances hath proved successful, given an hour before the fit of an ague, and an hour after it. They may perhaps contain an acrid oil, but their effect in agues is from the horror excited: they never cured, when the nature of the medicine was concealed. By this name are also called the coat and capsula of the crystalline humour of the eyes, named

also *speculum crystalloides tunica*. It is furnished with vessels from the ciliary processes, and from an artery which enters the bottom of the retina and runs through the vitreous humour.

ARA'NEA is also the appellation of the coat of the vitreous humour of the eye, from resembling a spider's web; called also *arachnoides*, a name added to it by Herophilus, according to Celsus. It is now called *vitrea tunica*. Dr. Nicholls, and Albinus, on injecting it, say that the vessels run on it like rays from a centre.

ARANEO'SA URI'NA. URINE, in which is something like spider webs, with an oiliness on the top. It indicates a colligation.

ARANEO'SUS PU'LSUS. A SPIDER LIKE PULSE. According to Galen, a small pulse that moves as if shaken by short puffs of air.

ARANEUS. See ARANEA; also ASTCHACHILLOS.

ARA'NGIA, ARA'NTIA. See AURANTIA HISPAN-  
LENSIS.

ARA'RA FRU'CTUS SECUN'DUS, or A'RARA FRU'CTUS AMERICA'NUS. (*Ararah*, Arab). It is a tree of the juniper kind, growing in Cayenne; and when bruised is applied to ulcers. Raii Hist. Its genus has not been ascertained.

ARA'SCON. See FUROR UTERINUS.

ARA'XOS. See FULIGO.

A'RBOR. A TREE; defined to be a plant of the largest growth, whose trunk is perennial and single, divided into many large branches, which are again subdivided into small twigs, on which the leaves, flowers, and fruit are produced. A'REOR AQUA'TICA BRASILIE'NSIS, see ANINGA; ARBOR CAMPHORIFERA, see LAURUS.

A'RBOR FARINI'FERA. See PA'LMA JAPO'NICA.

A'RBOR FEBRI'FUGA PERUVIA'NA. See CO'RTTEX PERUVIA'NUS.

A'RBOR INCA'NA SILIQUIS TORO'SIS. See CA'JAN.

A'RBOR I'NDICA FRU'CTU CONOI'DE, &c. See ANA-  
CA'RDUM.

A'RBOR JUCADI'CE. See CA'SSIA LI'GNEA; CANE'LLA A'LBA.

A'RBOR LANI'GERA SPINOSA. See BO'MBAX.

A'RBOR MALA'BARICA LACTE'SCENS, &c. See CO-  
NE'SSI.

A'RBOR MEXICA'NA. See ORLEA'NA.

A'RBOR NUCI'FERA. See ANDI'RA.

A'RBOR ST. THO'ME. See MANDA'RA.

A'RBOR SPINO'SA. See LY'CUM.

A'RBOR SPINO'SA I'NDICA, &c. See BO'NDUCH INDO'-  
RUM.

A'RBOR POMI'FERA, and PRUNIFE'RA I'NDICA. See ACAJAI'BA.

A'RBOR VINIFERA COUTON JUGLANDI SIMILIS. See COU'TON.

ARBOR DIANE. Silver precipitated by the superior affinity of some other metal in an arborescent form. Lead and tin produce similar appearances, and are styled ARBOR PLUMBI, and ARBOR STANNI; but the method of forming these trees has no relation to medicine.

ARBORE'SCENS, ARBORESCENT, (from *arbor*, a tree). See DENDROIDES.

ARBUSCULA CORA'LLII, or CORALLOI'DES, (a dim. of *arbor*). See CORALLODENDRON.

ARBUSCULA GUMMIFERA BRASILIENSIS. See CAMOPIA.

ARBU'STIVA, (from *arbor, a tree*). An order of plants of the shrubby kind.

ARBU'TUS PAPYRACEA, called also *papyracea, fragaroides, ferentis, fragaria*. The STRAWBERRY TREE. The fruit of this tree, called *unedo, comarus*, and *mamacylon*, is slightly cooling and relaxing, aperient, and a promoter of the urinary and alvine secretions: mixed with watery liquors the juice forms an useful drink in fevers. The jellies and inspissated juices are less flatulent than the raw fruit. See FRAGA.

This strawberry is like a quince tree, and is common in the south of Europe.

ARBU'TUS UVA URSI. See UVA URSI.

ARCÆTI, BALS. vel LINIM. vel UNG. See ELEMI.

ARCA'NNE. See OCHRA.

ARCA'NUM, (from *arca, a chest*). A secret, or a medicine whose preparation is kept from the world to enhance its value.

ARCA'NUM CORALLI'NUM. See MERCURIUS CORALLINUS.

ARCA'NUM DU'PLEX, or DUPLICA'TUM. See NITRUM.

ARCA'NUM JOVIA'LE, is a preparation of tin and quicksilver amalgamated and digested in spirit of nitre, but now disused.

ARCA'NUM MATERIA'LE. Among the chemists it is a specific extract, supposed to be allied to the matter of our bodies.

ARCA'NUM TA'RTARI. TE'RRÆ FOLIA'TA TARTARI. See DIURETICUS SAL.

ARCEUTHOS, (from *αρκε, evil*, and *κευθα, to drive away*). So called, because the smell of its leaves keeps off noxious animals. See JUNIPERUS.

ARCHE'US, (from *αρχη, the principal, chief, or first mover*). The supposed primum mobile of Helmont, which, in his opinion, superintended the animal economy, and preserved it. It resembles Plato's *anima mundi*. Hippocrates uses the words *αρχαινη φυσικη*, to signify the former healthy state before the attack of the disease. It is also a term coined by Paracelsus; by it he would express the sole active principle in the material world.

But however language has diversified the nature and operation of this principle, the existence of a power in the animal system, to correct accidental deviations from health, and to preserve the body in a sound state, is undeniable. When NATURE is said to act, such a principle must be intended. Van Helmont, who, among numerous fancies, possessed in many instances a sound judgment and extensive knowledge, placed his archæus in the stomach, and supposed it the grand regulator of the animal machine. Stahl adopted the principle, and extended its influence, without however fixing its throne in any one part. The system of Stahl was widely diffused in Germany, and for a long time obscured the humbler, but scarcely less industrious, labours of Hoffman; and to Stahl, Dr. Cullen has been more indebted than is generally supposed, or he was himself willing to acknowledge. The great point at issue between the disciples of Van Helmont and Stahl, and the more modern physiologists, is the action of this principle. Stahl contended, that nature acted from wide extensive views, consulting with consummate wisdom the good of the machine entrusted to her care. Dr. Cullen, while he admitted the benefits produced by the operations of nature, considered her action as the necessary

consequence of immutable laws; and denied that we in any instance possessed a power of acting, directed by means; chiefly since these means were beyond our knowledge; nor were we in many instances conscious even of the end or object. We need not expand this article by the arguments on either side. In the works of Stahl, particularly in his '*Theoria Medica Vera*,' and in the theses, published by his pupils, the whole doctrine is expanded with singular ingenuity, and supported with a logical precision, of which, in the annals of medicine, there is no example or imitation. It is more clearly explained in the works of Junker; for the language and the laboured precision of Stahl place him beyond the reach of many readers. As the principle is acknowledged, we ought to look to physiologists for its explanation: none has, however, been offered, except that hinted at above by Dr. Cullen. The power evidently does not reside in the immaterial principle, but is the result of changes more purely material; and such is the constitution of the animal machine, that, by being repeated, it obtains greater facility of action. Nature, then, often urged to supply deficiencies and correct deviations, acts more readily, and performs her office more successfully. In a future part of this work we shall resume the subject; and when the articles to which we must refer are before the reader, we may make some advances in the explanation. See VIRE'S NATURE.

ARCHANGE'LICA. See ANGELICA, and LAMUM ALBUM.

A'RCHE, *αρχη*. The first attack of a disease; its first stage; or that time of the disorder in which the patient first takes to his bed, or in which help might be effectual.

ARCHE'GENUS MO'RBUS, (from *αρχη, the beginning*, and *γενεσθαι, to be*). Holding the first rank in diseases. See ACU'TUS MO'RBUS.

ARCHE'NDA. Corrupted from the Arabic *alkenda, the ligustrum*, or *privet*. A powder prepared of the Egyptian privet, to be applied to the feet to check their fetid odour.

ARCHEZO'STIS, (from *αρχη, extremity*, and *ζωνωσα, to bind*). Because its tops or tendrils are apt to bind round whatever is in its reach. See BRYONIA ALBA.

ARCHIA'TER, (from *αρχη, chief*, and *ιατρος, a physician*). The principal physician at a court.

ARCHI'MIA, (from *αρχη, chief*, and *χημια, chemistry*). The art of changing imperfect into perfect metals.

ARCHI'THOLUS, (from *αρχη, and θολος, a chamber*). See ARCHICOLUM.

A'RGHOS, the ANUS. Also the INTESTINUM RECTUM.

ARCHOPTO'MA, (from *αρχος, anus*, and *πιπτω, to fall down*). A bearing down of the rectum. Vogel.

A'RCION. A'RCIUM. See BARDANA.

A'RCOS. See ÆS USTUM.

ARCTA'TA PARS. So Scribonius Largus calls a part compressed or closed by a fibula.

ARCTA'TIO, vel ARCTI'TUDO, (from *arcto, to make narrow*). It is when the intestines are constipated from an inflammation or spasm. Also a preternatural straitness of the *pudendum muliebre*.

A'CTION, (from *αρκτος, a bear*), so called from its roughness. See BARDANA ARCTICUM.

## A'RTICUM LAPPA, vel A'RTIUM MA'JOR.

See BARDANA MAJOR.

ARCTOSCO'RDON, (from *αρκτος*, a bear, and *σκορδον*, garlic). BEAR GARLIC.

ARCTOSTAPHYLOS, (from *αρκτος*, a bear, and *σταφυλη*, a berry, because wild bears feed upon them). SPANISH WORTLES.

ARCTURA, (from *arcto*, to straiten). Inflammation of the finger or the toe from a curvature of the nail. Linnæus.

ARCUA'LIA; vel NERVA'LIA OSSA, (from *arcus*, a bow, and *nervus*, a nerve,) because they have the form of a bow, and afford a passage for the nerves. The SINCIPUT; according to others the TEMPLE BONES.

ARCUA'LIS SUTURA. See CORONALIS SUTURA.

ARCUA'TIO. A gibbosity of the fore parts, with a curvature of the bone of the sternum, of the tibia, or dorsal vertebrae.

ARCUA'TUS MO'RBUS. So called, (from *arcus*, a bow,) either because the colour of the eyes is like a rainbow, or because of the rainbow like arch which is under the eye lids in the jaundice. See ICTERUS.

A'RCULÆ, (a dim. of *arca*, a chest). The orbits of the eyes.

A'RDAS, (from *αρδευω*, to defile). SORDES, FILTH.

A'RDENS FE'BRIS. The ARDENT FEVER, (from *ardeo*, to burn). It is also called *febris deurens*, *causodes*, and *cholericæ*; a BURNING, or HIGHLY ARDENT FEVER: by the Greeks called *causus*, (from *καω*, *uro*, to burn,) because it was attended with a burning heat. The ancients considered the extreme heat and unextinguishable thirst as characteristic symptoms of the disease. Hippocrates succinctly describes it, a fever attended with extreme heat, strong thirst, a rough and black tongue, complexion rather yellowish, and the sputum bilious. It is also elegantly described by Aretæus and Lommius. Sauvages arranges it under *tritæophya*, the second species; and Dr. Cullen places it among his examples of *tertian remittents*. At the beginning of this fever the heat to the touch is fiery, though unequal in different places; internally it is violent, though often the heat in the extremities is much less severe: sometimes indeed they are cold. The whole surface of the body, nose, mouth, and tongue, are dry; the breathing is short and quick; the tongue dry, yellow, sometimes black, rough, and chapped; the thirst is inextinguishable, and often goes off suddenly; there is a loathing of all solid food, nausea, accompanied often with a gnawing pain at the stomach, and heat of the precordia; vomiting, great anxiety, restlessness, and extreme lassitude; a slight cough also attends, with a hoarse voice, and, occasionally, delirium; to which succeed coma or convulsions: the exacerbations are not always on regular days. This fever, as it is very violent, is seldom of long continuance: if from the beginning the symptoms are favourable, it generally terminates on the fourth day; seldom exceeds the seventh; and either a vomiting, diarrhœa, sweat, or nasal hæmorrhage, proves critical. Young subjects are seized oftener, but bear it with more ease and safety, than older persons. The remote causes are debilitating ones of every kind, particularly when combined with hot weather; and the biliary system seems particularly affected; but the more immediate cause of this and all other remittent fevers is marsh effluvia. It is some-

times attended with an inflammation of the aorta and vena cava.

CURE.—We are first advised to bleed freely from a large orifice; and if the patient is robust, and the heat excessive, to support him on his feet until the operation is ended, that he may faint, if possible; as the heat is always less after fainting than when the same quantity of blood is discharged without this accident happening. If the pulse and the heat do not contraindicate it, the bleeding must be repeated at proper intervals.

Immediately after bleeding, let a brisk but cooling purgative be administered. Sydenham observes, that purging immediately after bleeding cools to a great degree; and that the method of curing fevers by perspiration is not only less certain, but more troublesome and tedious, nay, that it prolongs the disease, and endangers the patient. By this observation, however, he means that such inconveniences arise by the heating sudorifics, then employed, previous to evacuations. The proper purges are the saline, quickened, if necessary, by an infusion of senna. Glauber's salt, largely diluted in water gruel, with a small proportion of emetic tartar, should be frequently drunk till it operates either or both ways.

During the intervals of purging, frequent small draughts of acidulated, subtepid, liquors should be taken, and nitre, kali acetatum, and sal ammon. crud. may be properly given: and if to each dose of these as much antimonium tatarisatum, or vin. antim. is added as the stomach will easily retain, their advantages will be increased. Barley and oatmeal gruels are the properest kinds of aliment, and all such as contribute to keep the habit cool, and dilute the fluids. After four or five days, if no assistance has been obtained, the above method is improper; yet if the heat be great and the pulse strong, a moderate bleeding may be of use. A gentle laxative that is cooling may also be given by the mouth; and, until the crisis, let gentle diaphoretics and light broths be continued: for after the fifth or sixth day of an ardent fever, there is generally some difficulty to keep up the vital heat to that degree which is necessary to health, or the continuance of the necessary secretions.

If a nausea continues after the emetic is worked off, the common saline draughts may be given at proper intervals.

A diarrhœa may be critical, so should be attended to with care; and until the patient's strength is affected by it, nothing is required. If excessive, the cretaceous mixture, with the tinctura catechu, or the pulv. ipecacuanhæ c. cum opio, will restrain it. If delirium come on early, with a strong pulse, the bleeding must be repeated and cooling laxatives continued: if, at a later period, with spasms, and a low pulse, warm cordials must be given, blisters applied to the neck, and sinapisms to the feet. Sydenham asserts, that garlic bruised and applied to the feet quiets the delirium more effectually and speedier than blisters. For the general management, see FEBRIS. Hoffman's Syst. Rat. Med. Boerhaav. Aphorism. § 738. Sauvages' Nosol. Method. Cullen's Pract. of Phys. on Remittents. Lommii Opusculum Aureum.

ARDE'SIA HIBE'RNICA. See HIBERNICUS LAPIS.

A'RDOR. A very intense acute heat raised in our bodies.

A'RDOR URINÆ. See DYSURIA.

A'RDOR VENTRICULI. See CARDIALGIA.

A'REA. See ALOPECIA.

ARE'CA. Ray takes the *bahei coyolli* to be this nut. Also called *faufel*, *avellana Indiana versicolor*. *Caunga*. The INDIAN, and the MALABAR NUT.

It is the fruit of a species of palm tree which is met with in the East Indies, though reckoned among the species of cacao-nuts. The whole is about the size of a pullet's egg; under the outward coat is a succulent fruit, which, when fresh, the Indians masticate with the betel: it is brown on the outside, shaped like a nutmeg at one end, and flat at the other; within, white and marbled with purplish veins; rather insipid to the taste. Within we find the almond, which is more commonly employed: it is astringent and harsh like an acorn; but the lime usually added takes off the unpleasant taste. It is supposed to strengthen the stomach. The taste is indeed astringent, but in fact it is merely, like snuff, an expedient to avoid emui. Linnæus called this palm by the trivial name of *catechu*, because he erroneously supposed it to yield this drug.

A'RECA AME'RICANA, *oleracea* Lin. This is the cabbage tree; and what is styled the cabbage is a conical bud in the middle of the central leaves, consisting of the long leaves not yet expanded. It is found in the former species, but has not the delicate flavour of the present, which resembles the artichoke, and is not less wholesome than pleasant. The *fæcula* of these trees certainly resembles the *terra Japonica* in appearance, and approaches it in properties.

ARE'CA I'NDICA. See NUX MOSCHATA.

AREMA'ROS. See CINNABARIS.

ARE'NA. SAND OR GRAVEL IN THE KIDNEYS.

ARE'NA LITOR'ALIS, ARE'NA MA'RIS MARINÆ. SEA SAND.

It is heated in bags, and applied to parts that are pained. Hydropic people are also sweated by being covered with hot sand; and sailors cured of the scurvy by burying them to the neck in the sand of hot countries. See BALSÆUM.

ARENA'MEN, (from *arena*, sand,) so called, because it is procured from sandy places. See BOLUS ARMENA.

ARENA'TIO, or SABURRA'TIO. It is the casting of hot sand on the bodies of patients.

AREN'TES, (from *areo*, to dry up.) A sort of cupping glasses used by the ancients.

ARE'OLA, (a dim. of *area*, a void place,) called also *halo*, is a circle which surrounds the nipple on the breasts: in virgins, it is little and red; in pregnant women it is larger and more brown.

ARE'STA BO'VIS. See ANONIS.

ARETE'NOIDES. See ARYTÆNOIDES.

ARE'US. The title of a pessary mentioned by P. Egineta.

A'RFAR. See ARSENICUM ALBUM.

A'RGAL. See TARTARUM.

ARGASYLLIS, (from *argus*, a serpent, which it is said to resemble). See AMMONIACUM, GUM.

A'RGEMA, or A'RGEMON, (from *argos*, white). See ALBUGO OCULORUM. Vogel defines it, an ulcer-

ation of the cornea. It appears red on the outside of the iris, and white within it.

ARGEMO'NE MEXICA'NA. See PAPAVER SPINOSUM.

ARGENTINE FLOWERS. See ANTIMONY.

ARGE'NTUM, (from *argos*, white,) also called *argyrus*, *comes*, *Diana*, *brumazer*, LUNA, SILVER. Haiiy, vol. iii. p. 383.

The more obvious properties of silver are well known. Its specific gravity is 10.4743, nor can it be calcined, or raised in vapour by any heat hitherto tried. It yields only to the nitrous acid and hepatic preparations, whether fluid or in the form of gas. When dissolved, its salts are peculiarly acrid; and coloured, or in some degree reduced by light. Silver itself is so little affected by any chemical agents, that it was preferred as the material of vessels, in which the nicest and minutest chemical experiments were usually made; but as we have now learnt to render platina malleable, the latter is preferred, since copper, the almost necessary alloy of silver, is affected by many bodies which do not act on the metal itself. Van Swieten tells us, that wine kept in a silver vessel in this way, became deleterious.

Nitrous acid or aqua fortis is almost its only solvent; and we thus prepare what is styled the *lunar caustic* for external use. Pure silver is dissolved in four times its weight of diluted nitrous acid, and the water evaporated. The salt is melted at first with a moderate fire, till the ebullition ceases, then with a stronger, till the matter runs like oil, in which state it is cast in moulds. The caustic thus formed deliquesces in the air, and is inflammable; the silver, during the combustion, separating in a pure state. For its mode of application see CAUTERIA under ESCHAROTICA.

The nitrated solution of silver, previous to the evaporation, should be transparent. It has been used, under the appellation of aqua græca, to blacken the hair; but must be greatly diluted, and employed with caution.

The lapis infernalis, under the name of nitrated silver, has been given internally by Boyle and Boerhaave. The latter thought highly of its virtues in dropsy when mixed with an equal quantity of nitre, and has told us that it occasioned the discharge of water in large quantities. Modern practice has recommended it in epilepsies, and angina pectoris. We have already had occasion to remark that all metals are apparently tonics or antispasmodics, and silver is probably of this number. From its acrimony it may also prove cathartic, as has been said, but our own experience has been too inconsiderable with this medicine to enable us to recommend it from observation. The dose should not exceed  $\frac{1}{4}$  of a grain: it is perhaps best to begin with  $\frac{1}{8}$  or  $\frac{1}{6}$ .

Angelus Sala recommended for similar diseases the CATHARTICUM LUNÆ, MAGISTERIUM HYDRAGOGUM, or DEJECTORIUM. This was a filtrated solution of nitrated silver crystallized. Of this salt he gave from six to eight grains, but found it so rough and uncertain that he soon disused it. Of his LUNA POTABILIS, recommended in delirium, he has given no formula: but his BEZOARDICUM LUNARE consisted of equal parts of glass of antimony and calx of silver. Lemery's TINCTURA LUNÆ was made with the impure metal, and owed

its chief virtue to the copper with which the silver was alloyed.

ARGENTUM VIVUM; called also *hydrargyrum*; a term now used by the college of London, *mercurius*, *liquor metallicus*, *metallum fluidum*, *argentum fusum*, *et mobile*, *mercurius*, *chemicorum*, *vomica liquoris aterni*; *aludit*; *anatri*; *alambic*; *alborca anterit*; *dadalus*; *alcarith*, *alecarith*, *alkaut*, *ebesmech*; *fons chemie*; *geryon*; *guma*; *ignis*; *almarkasita*; *alohar*; *alohoc*; *musalis*; *massariam*; *mater metallorum*; *ziback*; *alosat*; *altaris*; QUICKSILVER. Haüy, vol. iii. p. 423.

Its chemical character is  $\gamma$ , which denotes that the inside is pure gold, but the outer part is of the colour of silver; with a corrosive underneath.

Its being a metal has been disputed; but it is now found that at about  $40^{\circ}$  below 0 of Fahrenheit it becomes solid and malleable. In the Venetian territories are the greatest quantity of mines producing quicksilver; the East Indies, Spain, and Hungary, afford great quantities of it; in China, Japan, and about Montpelier in France, there are mines in which it is found.

It is found in the earth in a fluid form, sometimes so pure as not to require refining, when it is called *virgin quicksilver*; but most frequently it is mixed with other substances. The most general state in which it is met with in the mines is in sulphureous ores of a red colour, called *cinnabar*, whose colour is deeper in proportion to its richness.

From the ore it is separated by washing in water, grinding with vinegar and a little salt, which dissolves the metalline impurities; and by distillation, either alone or with the addition of lime, potash, or iron filings.

The people who work in the quicksilver mines soon die: when first affected they are seized with tremors, after which a salivation comes on, their teeth drop out, and pains of the whole body, particularly of the bones, seize them.

Hippocrates does not seem to have been acquainted with this mineral; Aristotle and Dioscorides rank it amongst poisons; Galen says that it is corrosive; Mesue, the Arabian, was the first who used it medicinally, and he only applied it in the form of an ointment in cutaneous distempers. Avicenna observes that it may be swallowed crude, and that it passes through the body. About the end of the thirteenth century it was introduced into Europe as a medicine, but not esteemed a safe one until the venereal disease was found to yield to its efficacy. The first internal mercurial medicine which gained real credit was the *pilul. Barbarossæ*, which was composed of quicksilver, rhubarb, and musk. The term quack, originally quacksalber, was a name of this metal, and applied to the irregular indiscriminate use of it.

It is the heaviest of all bodies except gold. Mercury is to gold nearly as 3 to 4; and to water as 13.5681 to 1.0000.

It is totally volatile in the fire by heat not much greater than that of boiling water, and by a far less heat it is calcined into a red powder. The fumes raised by fire are scarcely visible; and yet, by being received into cold water, may be reduced to the state of pure quicksilver. It rises also in vapour, in the vacuum of the Toricellian tube.

It amalgamates most readily with gold, and in suc-

cession with lead, silver, and tin; scarcely at all with iron or copper. By the assistance of trituration, or of heat, it dissolves all metallic bodies except iron.

The vitriolic acid hath no effect upon it until concentrated by heat; the nitrous acid acts quickly upon it; and the muriatic scarcely at all until it is oxidated: fixed salts, vegetable acids, and neutral salts, scarcely alter it in any way. It is allowed to be pure when a little held over a fire, in an iron ladle, totally evaporates.

It is often adulterated with lead; a large quantity of which may be incorporated with it by the intervention of bismuth in a moderate heat; and in this case the lead cannot be separated by pressure through leather. This abuse may be discovered by the mercury staining paper blackish; by its not running into round globules; by its leaving a powdery matter or a coloured spot on the bottom of the vessel; and by its producing a turbid milkiness during its solution in aqua fortis.

As a medicine, it is used to promote the secretions in general, particularly the saliva. The more perfectly it is divided, the more powerful and penetrating is its action, which is chiefly exerted in the small vessels. Whether used internally or externally it affects all the vessels in our bodies, and may be so managed as to promote excretions through all the emunctories. If not restrained, it is determined to the mouth, and causes inflammation, tumours, ulcerations, and constantly an increased discharge of saliva.

Mercury, like antimony, has been tortured in many different ways, but the result of the chemists' and alchemists' labours has been fortunate. We have obtained by their means a considerable variety of active preparations, which are of the greatest importance in the healing art. We shall, as in the article of Antimony, first examine the preparations retained by the colleges of these kingdoms, and then notice some of the more important formulæ formerly recommended, or still valued. The mind will not in this way be distracted by a multitude of objects, and what the enquirer chiefly wants he will readily find.

Mercury is employed

I. Purified by distillation.

*Hydrargyrum purificatum* (Dublin. London).

II. Slightly oxidated

$\alpha$  By precipitation of nitrated mercury by means of ammonia.

*Oxidum hydrargyri cinereum* (Ed.).

*Pulvis hydrargyri cinereus* (Dublin).

$\beta$  By trituration.

1. With unctuous substances.

*Unguentum hydrargyri* (Ed.).

\_\_\_\_\_ fortius (Lond. Dublin).

\_\_\_\_\_ mitius, *ibid.*

*Emplastrum ammoniaci cum hydrargyro.*

\_\_\_\_\_ lithargyri cum hydrargyro.

\_\_\_\_\_ hydrargyri (Ed.).

2. With saccharine substances.

*Pilulæ hydrargyri* (Lond. Dub. Ed.).

3. With aerated lime.

*Pulvis hydrargyri cum cretâ* (Lond.).

III. Considerably oxidated

$\alpha$  By heat and air.

*Hydrargyrum calcinatum* (Lond. Dublin)

- β By nitrous acid.  
 Oxidium hydrargyri rubrum per oxidum nitricum (Edin.).  
 Hydrargyrum subnitratum (Dublin).  
 Hydrargyrus nitratus ruber (Lond.).  
 Unguentum oxidi hydrargyri rubri (Edin.).
- IV. Oxidated and combined with acids.
1. More slightly.
    - a With the nitrous acid.  
 Unguentum hydrargyri nitrati (Lond. Dub. Edin.).
    - β With sulphuric acid.  
 Subsulphas hydrargyri (Edin.).  
 Hydrargyrum subvitriolatum (Dub.).  
 Hydrargyrus vitriolatus (London).
    - γ With muriatic acid.
      1. Sublimation.  
 Submurius hydrargyri (Edin.).  
 Hydrargyrum muriatum mite sublimatum (Dublin).  
 Calomelas (London).
      2. By precipitation.  
 Submurius hydrargyri præcipitatus (Edin.).  
 Hydrargyrum muriatum mite præcipitatum (Dublin).  
 Hydrargyrus muriatus mitis (London).
    - δ With acetous acid.  
 Acetis hydrargyri (Edin.).  
 Hydrargyrum acetatum (Lond. Dub.).
  2. More completely.  
 Muriats.  
 Murias hydrargyri (Edin.).  
 Hydrargyrum muriatus (London).  
 Hydrargyrum muriatum corrosivum (Dub.).  
 With ammonia.  
 Calx hydrargyri alba (London).
- V. Combined with sulphur.
1. By trituration.  
 Sulphuretum hydrargyri nigrum (Edin.).  
 Hydrargyrum sulphuratum nigrum (London. Dublin).
  2. By sublimation.  
 Hydrargyrum sulphuratum rubrum (London. Dublin).

Mercury differs from antimony in one important respect, viz. that its calces are not inert in proportion to their degree of oxidation: in fact, the more highly oxidated metallic salts and calces are among its more active preparations. In the first stage of oxidation we find mercury assume a grey colour; and in this state, as appears by the table, it exists in plasters and ointments, and formerly existed in some other preparations now chiefly confined to private practice. The only remaining preparations of this kind are, the *pulvis hydrargyri cum cretâ*, and the *pillule hydrargyri*, of the three colleges. The latter differ only in the proportions; for one grain of mercury is contained in four grains of the Edinburgh pill, three in that of London, and two and a half in the Dublin form. It has occasioned some anxiety to learn in these preparations the source of the acid, for an acid was thought necessary. We now find that oxygen is chiefly required; yet it has been discovered that electricity has, or possibly the Galvanic

fluid, some share, since the preparation differs according to the nature of the vessels employed. A similar powder is the result of agitating pure quicksilver in water, but the source of the oxygen is there sufficiently obvious.

The difficulty of obtaining a complete extinction of the quicksilver by trituration, induced the Edinburgh and Dublin colleges to precipitate the mercury from its solution in the nitrous acid by means of ammonia. The *oxidum hydrargyri cinereum*, and *pulvis hydrargyri cinereus*, are the results of this plan. The oxide is, however, not pure, for it contains the oxide of mercury with ammonia not saturated with nitric acid. Fourcroy has remarked, that a part of this salt is soluble in the acetous acid; and the remainder, a pure subnitrate of mercury and ammonia, crystallizes in brilliant polyhedral crystals, extremely styptic, and scarcely soluble in water; consisting of 68.2 of oxide, 16 of ammonia, and 15.8 of nitric acid. Though this be different from the grey oxide, yet we think it deserves a trial. The *black oxide* may be prepared also by triturating the calomel (in modern language the sublimed submuriate of mercury) in lime water. The decomposition is said to be more complete if the precipitated submuriate is employed; the preparation generally known by the name of calomel in the humid way.

A pure oxide of mercury with a larger proportion of oxygen occurs in the *hydrargyrum calcinatum* of the London and Dublin Dispensatories. The process is slow and tedious; but the preparation, if carefully levigated, highly useful. Its acrimony must, however, be guarded by opium; or it will prove emetic and purgative. In a long practice, it is not uncommon to feel at different periods a predilection for different preparations of mercury; and, perhaps, at this time we may be peculiarly fond of the present preparation. It seems, however, to perform every thing which the most celebrated mercurials have effected, and not to be more inconvenient. Yet, perhaps, in every instance, calomel will do as much.

Mercury, oxidated by nitrous acid, has been much employed; *hydrargyrus nitratus ruber* of the London Dispensatory; *oxidum hydrargyri rubrum per oxidum nitricum* of the Edinburgh; and *hydrargyrum subnitratum* of the Dublin: yet it scarcely differs from the mercurius calcinatus, except in the convenience and the facility of the preparation. The metal is first united with the acid; then the latter decomposed and separated by heat. In general, the acid exceeds in a small proportion the weight of the quicksilver; but the London college renders the proportions equal, adding a little muriatic acid, which it is supposed increases the size and beauty of the red scales. This advantage is, however, equivocal; and the little difference in the proportion of the acid of scarcely any importance except in an economical view. If too small, the continued heat compensates the inconvenience. The *ointment* contains one part of the oxide to eight of hogs' lard.

The oxides of mercury, combined with acids, are preparations of great importance. In the old *unguentum citrinum*, *unguentum hydrargyri nitrati*, we find the only instance of its combination with the nitrous acid. With the vitriolic acid it forms the *hydrargyrus vitriol-*

*latus* of the London, and the *subsulphas hydrargyri flavus* of the Edinburgh. The very singular process by which this medicine is prepared, M. Fourcroy has very industriously and ingeniously analysed. When the acid is added to the metal, no action takes place; but when heat is applied, a part of the acid is decomposed and the metal oxidated, uniting with the remainder of the acid. The salt thus formed is white, but the acid is in excess. When the superfluous acid is separated, this salt crystallizes in fine prismatic needles; is soluble in about five hundred parts of cold water, and in half that proportion of warm, without decomposition. A little sulphuric acid increases its solubility. In this state Fourcroy found that it contained seventy-five of the metal, twelve of the acid, eight of oxygen, and five of water, in one hundred parts.

In the processes of the colleges, the saline solution is boiled to dryness, so that more of the acid is decomposed, and a larger proportion of sulphureous acid gas evolved. If then, as directed, it is thrown into boiling water, a yellow powder, the *hydrargyrus vitriolatus*, is formed. What is effected by this part of the process M. Fourcroy discovered by examining the different portions. The water contained a salt with more than its proportion of acid: of course, the powder had a diminished proportion, and the effusion of the hot water dissolving as much of the salt as it could take up with its acid, left the powder deprived of it. It consisted, on analysis, of seventy-six parts of mercury, and eleven of oxygen. The taste is acrid; it is soluble in two thousand parts of cold water, decomposed by the nitrous and muriatic acids, oxidizes quicksilver, and is converted by trituration with it into a black powder. Such is the outline of this author's labour; and chemistry does not furnish an analysis at once so accurate, so elegant, and satisfactory.

The muriatic acid furnishes preparations of the greatest use and importance in medicine. In the *calomel* of the London Pharmacopœia, the *submuriat hydrargyri* of the London, and the *hydrargyrum muriatum mite sublimatum* of the Dublin, prepared by sublimation, the metal is oxidated more slightly. But before we can notice these we must step forward in the table to the muriats, and the three different titles express only the combination of the metal with the muriatic acid, generally known by the appellation of corrosive sublimate. In all the preparations the mercury is oxidated by sulphuric acid, and then combined with the muriatic, by subliming it with a mixture of common salt. The taste is peculiarly acrid and styptic: it is soluble in twenty parts of cold, and in about two of boiling water; in nearly four parts of alcohol at 70°, and in an equal weight of alcohol in a boiling state. It is unaltered in the air, in sublimation, or by either of the mineral acids. Its solubility is increased by the addition of a small proportion of crude sal ammoniac. It is precipitated by all alkalis and earths; those not carbonated form a yellow precipitate; the others an orange yellow, changing to a brick red. It consists of oxide of mercury 0.82, and of acid 0.18. The oxide itself containing 0.15 of oxygen.

The calomel, and the synonymous formulæ which precede, are prepared from this muriat of mercury. The principle of the preparation is obvious, when it is recollected that earths and metals, unlike alkalis, may

be combined with different portions of acid, and still be in appearance neutral. In the muriat of mercury there is no apparent excess of acid; yet nearly an equal proportion of the metal may be combined with it, and partake not only of its acid but its oxygen. About nine ounces of the metal are added to a pound of the muriat, and united by trituration. The newly added metal shows immediately appearances of oxygenation, but the combination is effected only by repeated sublimation and trituration. The London college orders this process to be repeated four times; an extraordinary precaution, certainly not necessary. Generally twice is sufficient; but we have sometimes found the union not perfectly complete, and a third sublimation is occasionally necessary. From Mr. Chevenix's experiments also there seems to be an unnecessary waste of quicksilver, a less proportion, 0.54, for instance, appearing sufficient. He considers the excess, however, a necessary precaution. The utility of calomel, which may be perhaps considered as an *instar omnium* with respect to the other mercurial preparations, for it is in every instance equally useful with any other, and in many cases greatly superior, has induced chemists to attempt with great diligence an easier and more certain mode of preparing it. The great object is to avoid the necessity of very long and careful trituration; for the calomel forming by sublimation a very hard solid mass, consisting of a confused aggragation of tetradral prisms, terminated by pyramids, the most careful attention is necessary lest any spiculæ should remain. Calomel has, consequently, been prepared in the humid way; first, if we recollect rightly, by Scheele, and afterwards more accurately by Gottling. It is now found in the Dublin and Edinburgh Dispensatories with the epithet *precipitatum*; and in that of London, under the title of *hydrargyrus muriatus mitis*. The principle of the process consists in forming a nitrated solution of mercury with an excess of oxide, to which a dilute solution of common salt is added. It was supposed that the decomposition of the nitrated mercury immediately took place, and that the powder deposited was calomel. Mr. Chevenix, however, has given us some reason to doubt the justness of this conclusion; and as water, the menstruum of the salt, will decompose nitrated quicksilver, the precipitate is probably a subnitrate of quicksilver, together with the submuriate. He consequently proposes adding to the water a little muriatic acid, or to employ a nitrated quicksilver without heat. To either proposal no reasonable objection can be made: yet it has been suggested by good authority, that the quicksilver in the nitrated salt is too highly oxidated—for, if the preparation be made by boiling, the proportion of oxygen is greater—and that the solution has been found to contain muriated quicksilver. We have repeated the process with this view without finding the same result; yet we think it should teach us to render our solution of common salt more concentrated, and the two fluids should be added at once, that the moment a particle of water touches the metallic solution, the latter should be met also by a portion of the common salt. In the usual preparations there is always a little of the nitrated mercury; for on rubbing the precipitates with lime water, the powder is grey and not black. When again sublimed, this nitrated mercury is decomposed, and a sublimation is consequently recommended. We find in our minutes a pro-

posal of again repeating the addition of a solution of common salt, and edulcorating the powder by washing; but do not recollect that the experiment was tried.

Hermstædt recommends a process of preparing calomel from the sulphat of mercury, to which nearly the original quantity of mercury is to be united by trituration. The muriat of soda is then added, the whole mass sublimed, the trituration and sublimation a second time repeated. This preparation has not been chemically examined, and we do not know its peculiar advantages. On the whole, perhaps, the old method of preparing the calomel forms the most certain and best preparation, if the subordinate agents can be depended on in the trituration; and as their error can be detected by a nice eye, inconveniences will not often occur: indeed, in the shops of the greater number of apothecaries no such are found. Calomel, according to Mr. Chevenix, contains 88.5 of oxide of quicksilver, and 11.5 of muriatic acid: the oxide amounts to 0.107, while the muriate contains 0.15 of oxygen. Fourcroy estimates the oxides differently: he makes three species, the black, the red, and one other still higher, not to be obtained separately; the black and red containing, respectively, 0.04 and 0.08 of oxygen. These different results have not been reconciled, and as the disquisition would be purely chemical we shall not attempt it.

Chemists expected to form milder and more convenient preparations of mercury with the acetic acid; and the reputation of Keyser's pills, which were found to be a combination of this kind, seemed to confirm the opinion. In the preparations of the three colleges nitrate of mercury is first formed with a gentle heat, which neither occasions it to take up an excess of acid, nor, as in case of boiling, to absorb and oxidate a larger proportion of the metal. A solution of acetated potash is then added, and the acetite of mercury crystallises, leaving the nitrate of potash, formed, in the preparation on account of its greater solubility in the fluid. It dries slowly, and should be compressed in bibulous paper. We have not found it to possess any advantages above the other mercurial preparations.

Combined with sulphur, mercury is seldom employed internally. Of the medical effects of the Æthiops mineral we have already spoken; but we must now consider shortly the chemical relations of this union, to complete the chemical history of the metal before us.

The black sulphurated quicksilver is not merely a combination of the sulphur and the metal, as authors have supposed. Quicksilver never assumes the form of a black powder, without having absorbed some portion of oxygen. Others have suspected that hydrogen is also united, and think that the process is expedited by adding a little water, whose decomposition supplies both. It is dissolved by the aqua kali, but unaffected by nitrous acid. From the solution of kali it is recovered unchanged by acids, and in the fire it suffers no alteration. When hot quicksilver is thrown into melted sulphur, and the whole stirred till cold, the same preparation in appearance results: the union is not however so complete; it is not soluble in the solution of kali, and is changed by the air. Berthollet supports the idea of its containing hydrogen by this remark, that

the Æthiops mineral may be prepared by agitating mercury with sulphurated, hydrogenated ammonia. This preparation also admits of change from the air.

The *hydrargyrum sulphuratum rubrum* is the *factitious cinnabar*, a medicine formerly used as a tonic, a stimulant, and a deobstruent; in short, for every object of which the prescriber had no distinct idea. It is now only employed as a fumigation in venereal complaints. It is not soluble in any acid; but the *nitro-muriatic* takes up the metal and leaves the sulphur. Alkalis, in a boiling heat, will not affect it; but, when melted, these and many of the metals decompose it. M. Proust supposes, that the quicksilver which it contains is not oxidated, but that it is in the proportion of 85 to 100, and that the remainder is sulphur.

The variety of other preparations of mercury, employed by physicians and surgeons of different countries, at different periods, would fill a volume. As we cannot enumerate every remedy of this kind, so preparations often celebrated must not be wholly overlooked. We shall not immediately follow the same order; but first divide the preparations according to their pharmaceutical forms, viz. ointments, plasters, pills, syrups, troches, drops.

The MERCURIAL OINTMENTS have been varied in every possible way according to the objects for which they were designed. Turpentine was formerly the general intermede to divide the crude mercury, and the additions were adapted to the disease for which it was employed. In the various *unguenta ad pediculos* we find the seeds of stavisacre, extract of tobacco, the roots of white hellebore, and oleum laurinum added. In Mynsicht's formula, the quicksilver is divided by the saliva of a person fasting. When to cure the itch, sulphur, alum, and white hellebore, are united with the metal; against worms, the gall of an ox, and oil of bitter almonds; in cutaneous diseases, by Stahl, preparations of lead and a portion of camphor; and, in the unguentum ophthalmicum of Hecker, nitrated mercury is united with camphor.

The MERCURIAL PLASTERS and CERATES have not been greatly varied from those directed in the different British Pharmacopœias. *Plenck's cerate* is made with mercury, divided by mucilage, as in his other preparations. It has been doubted, whether in this form the mercury is absorbed. Mercurial plasters have often no effect; but after their application we sometimes have found pains in the stomach and bowels, which are relieved by removing the plaster; and, in one or two instances, salivation has followed.

The MERCURIAL PILLS have been very various. *Barbarossa's pills*, named from the celebrated Algerine who gave the process to Francis I. consisted of mercury, with a small proportion of rhubarb and scammony, formed into a mass with lemon juice. *Plenck's pilula ex mercurio gummoso*, consisted each of a grain of mercury, extinguished by starch and gum arabic, with sometimes a small proportion of rhubarb; and, indeed, some of the forms used in this country contain a mixture of some active cathartics. It were endless to follow all the varieties directed in different Dispensatories, varying only by the mode of extinguishing the quicksilver, and the peculiar additions. The magnetic pills of Ostius are prepared with the mercurius calcinatus, with a large proportion of some vegetable ex-

tract, which has not been accurately ascertained; and Keyser's pills, with the acetite of mercury. These last are now disused; and, whatever was once their credit, the testimony of Murray, Girtanner, Quarin, and Columbier, seems to have destroyed it.

Of the SYRUPS *Plenck's mercurial syrup* is well known. Bellet asserts that *his* syrup contains no mineral acid. Girtanner, however, and Swediaur, have ascertained that the mercury has been dissolved in the nitrous acid precipitated by the vegetable alkali, then dissolved in vitriolic æther, and sweetened. The precipitate of which it is formed was found to retain no inconsiderable proportion of the acid. Girtanner also informs us, that Veluo's syrup does not differ from Bellet's. The *rob antisiphiliticum* of L'Affecteur is nearly similar; but some authors contend that a small portion of corrosive sublimate is added.

The various TROCHES, particularly the *anthelmintic rotula* and *tabellæ* of Morelli, Zwelfer, and Le Mort, as well as the *rotula infantiles laxativa* of Schroeder, owe their virtue to calomel and some active cathartic. In these we may find the source of the various worm-cakes and lozenges, celebrated by names of high respectability in this country, who do not, however, rank among medical authorities. The *secret remedy* of Nicole is formed into little cakes, and supposed to contain corrosive sublimate, though denied by the author. The *trochisci tonici mercuriales* of Bru, are formed by an oporose process which we need not particularly describe, as the medicine is no longer employed: they consist of a mixture of turpeth mineral with white precipitate, and are made into lozenges with honey, sugar, and meal. Each lozenge contains about two grains of mercury.

The drops contain mercury so much concentrated as to be given in very small doses. Of *Ward's drops* we now know the form. They consist of mercury precipitated from its solution in aqua fortis by the volatile alkali, and again dissolved in rose water. The *antivenereal tincture*, or *quintessence* of Mollet, contains mercury united with the muriated ammonia, a subject on which we shall soon again speak. The *liquor mercurii secretus* of Gmelin is given in drops, but it contains little or no mercury. Four ounces of the muriated mercury are dissolved in twelve ounces of vinegar: the fluid is drawn off, and the residuum infused, repeatedly, in spirit of wine, which is drawn off by distillation after being for many days digested in a gentle heat. Libavius' *tincture of quicksilver* contains as little of the mercury. Nitrated quicksilver is digested with the brown oil of vitriol, which is repeatedly drawn off till the residuum becomes red. From this, spirit of wine is also repeatedly distilled and somewhat inspissated.

The *Thibet remedy*, described by Mr. Saunders in the 79th volume of the Philosophical Transactions, merits also some notice. It consists of a portion of alum, nitre, vermilion, and quicksilver sublimed, and appears to be a nitrated mercury of a mild operation.

The *drops* of General La Motte are of a beautiful red colour, and supposed to be preparations of red precipitate or cinnabar in an acrid fluid, of which a few drops are taken in tea. The *elixir antisiphiliticum* of Bouez de Sigogne is, in the opinion of Astruc, similar, and the dose, as well as the mode of exhibition, the same.

We shall next follow the less common preparations of

mercury in a chemical order. In speaking of the *sulphurated preparations* of mercury we need not enlarge on the *Æthiops mineral*, though its formula has been infinitely varied, and numerous discussions on its virtues and preparations lie before us. The *Æthiops mineral* forms the basis of the *pilula Æthiopica* of the Wirtemberg Dispensatory, in which this preparation supplies the place of calomel, in a formula not unlike Plummer's. The *Æthiops narcoticus* of Jacobi, described in the *Acta Naturæ Curiosorum*, is more curious. Two ounces of quicksilver are dissolved in four ounces of smoking nitrous acid, and boiled with two pounds of a caustic lixivium, two ounces of potash, and four ounces of sulphur. The sediment is well washed, and is the *fulvis narcoticus*. This powder, triturated for three days with the *Æthiops mineral*, becomes, it is said, an active antisiphilitic, without producing salivation. *Navier's mercurial*, said to be particularly useful in scrofulous and cutaneous complaints, is prepared by precipitating mercury dissolved in hepar sulphuris by any *chalybeate* neutral. The *panacea mercurialis nigra*, the *panacea* of Schroeder, consists of mercury, sulphur, and sal ammoniac, united by sublimation. It differs little from cinnabar except in its darker colour. The *panacea Anwaldina* is chiefly cinnabar, with some saffron and oyster shells. The *cinnabaris cerulea* of Wallerius, *mercurius violaceus Parisiensium* of Triller, and the *mercurius violaceus diaphoreticus* of Astruc, differ only in colour from cinnabar; a change occasioned by a combination of sal ammoniac. The *mercurius diaphoreticus* of Sir Kenelm Digby is prepared by subliming a pound of mercury with four ounces of sulphur auratum antimoni.

The union of mercury with other metals has been often attempted, and the compound supposed to be highly useful. With lead it has been employed in the iliac passion; with tin against worms; and with iron in chronic disorders. Corrosive sublimate dissolved in water, mixed with a solution of iron in vinegar, we are told by Navier, is void of acrimony, and useful in many chronic diseases. The *mercurius dulcis martiatus* of Hartmann, is a similar union of a martial calx with mercury.

The *mercurius diaphoreticus* consists of the calces of mercury and antimony with a calx of gold; for gold has been always considered as a cordial and a diaphoretic. It is celebrated even by Hoffman, under the name of the *solar precipitate*, *Hercules bovi*, and *auri vitæ Clossæi*. The *panacea de la vigne* contains mercury with gold and silver; the *precipitatus solaris*, with gold only; and many similar ridiculous preparations are described by Zwelfer, Hercules Saxonia, Schroeder, Hartmann, Jungken, and Lemery, under the titles *mercurius dulcis solaris*, *mannu mercurii*, and *arcanum corallinum*. The *mercurius precipitatus viridis*, or *lacerta viridis*, contains copper united with mercury.

The CALCES OF MERCURY next claim our attention. Dr. Priestley informed us, that mercury triturated with water might be changed into a black powder; but the fact was published by Homberg in the Memoirs of the Academy of Sciences for 1700. This preparation, if it may be so called, has been highly celebrated under the name of *Æthiops mineralis per se*; more properly, *mercurius oxidatus niger*: but its chief use has been to unite with the vegetable acid in

making Keyser's pills; and, triturated with axunge, to prepare extemporaneously the mercurial ointment. The *fulvis wigonis* is only the *mercurius calcinatus*; and Schroeder's *precipitatus dulcis* is prepared by calcining quicksilver with the red precipitate which has been de-flagrated with spirit of wine. The red precipitate itself is the preparation which distinguishes Girtanner's unguentum rubrum; and forms, with burnt alum, euphorbium, dry leaves of savine, the roots of iris, and aristolochia rotunda, the *fulvis catharticus*, for carious bones, of Schroeder. With minium and ceruse it forms the *unguentum piacentinum* of the hospital at Padua; and with tutty, nitre, and camphor, the celebrated ointment of Mursinna for restoring the transparency of the cornea. The *precipitatum nobile* of Angelus Sala is only the red precipitate with a small portion of the muriatic acid; since it is prepared by calcining a solution of a calx of mercury in aqua regia. It is highly commended by its author in a malignant itch. The *arcantum corallinum* and *mercurius corallinus* are preparations of Crolius, described in Lewis's Dispensatory; and the *laudanum minerale* of Hartmann is the former, first digested with vinegar, which is again separated by distillation, and afterwards with spirit of wine. It is supposed to be a gentle laxative, and then an anodyne and sudorific. The *rosa vite mineralis* is the red precipitate, digested four times with spirit of wine. The *panacea mercurialis rubra*, *precipitatus diaphoreticus excellens*, *turbith minerale rubrum Zwelferi*; *fulvis principis*, and *mercurius antivenereus* of Hartmann, are similar preparations, in which the red precipitate is rendered milder by digesting it with spirit of wine. In the two last it is previously elutriated with water, to which an alkali is added in some of the latter washings. Various similar preparations of mercury are found in chemical authors; but we shall only notice Hahnemann's *mercurius solubilis*, which, in his Chemical Annals for 1790, he mentions with the warmest commendations, as producing no inconvenience in the stomach or bowels, being soluble in vinegar and in the animal fluids, and easily absorbed when applied externally. It seems to be a calx of mercury, precipitated from a solution of the metal in pure aqua fortis by the caustic spirit of sal ammoniac. This preparation has been also called *turbith nigrum*.

The greater number of the calces of mercury have some remaining saline matter, and this is particularly the case with the *mercurius precipitatus albus*, the *calx hydrargyri alba*, which we again mention to introduce its numerous singular synonyms. These are *mercurius cosmeticus*; *lac mercuriale*; *calcinatum majus poterii*; *panacea mercurii albi*; *catharticum mercuriale*; and, when washed, *mauna mercurii*. It is chiefly used on the continent as an external application, and is highly commended in the itch. Authors of credit have, however, we perceive, given it internally, and speak highly in its favour: when sublimed, dissolved in water, and again sublimed, it is styled *aquila celestis*.

A modern preparation of mercury similar to Hahnemann's *mercurius solubilis*, is the *hydrargyrum nigratum cinereum* of Swediaur; *fulvis mercurii cinereus* of Girtanner; called, for a reason that we cannot develop, *mercurius cinereus* of Black. It is mercury, precipitated from its solution in aqua fortis by a mild volatile alkali, and is of a lighter colour than the *turbith nigrum*.

The *precipitatus luteus* of Hartmann is not greatly different, as it is precipitated by a mild fixed alkali, and acquires its yellow colour by washing. The *precipitatus luteus diaphoreticus* of the same author is a solution of the corrosive sublimate, precipitated by the same alkali, and carefully washed. *Mercurius dejectorius*, or the *flores argenti*, is the *precipitatus luteus* of Hartmann, digested in the acetous acid, and then washed. The *precipitatus correctus* of Schroeder is prepared by dissolving the white precipitate in vinegar, and again separating it by a fixed vegetable alkali.

The improved chemistry has introduced some new preparations of mercury. The first that occurs to us is the *mercurius phosphoratus*, *sal phosphoricum mercuriale*, and *phosphoras mercurii*, with some similar appellations. It is a white salt, unchanged in the air, and scarcely soluble in water, prepared by precipitating mercury from its solution in aqua fortis by the phosphoric acid. This preparation is slightly mentioned by Girtanner and Swediaur, but chiefly introduced by a French quack, M. Mittie, followed by a German, J. Fr. Schmidt. It is highly praised in the worst stages of syphilis, particularly in the most inveterate kinds when the bones are affected, and is given with aromatics to prevent its exciting nausea, in the dose of half a grain, or a grain. We own that these assertions are to us suspicious: we know that the use of phosphorus is dangerous, and have no reason, from the facts adduced by the admirers of the phosphorated mercury, to suppose that this is a safe or manageable preparation. We can add, that it is by no means new; for we observe in Angelus Sala a preparation styled *fulvis rosa vite*, copied by Hartmann, who calls it *mercurius incarnatus precipitatus*, in which the nitrated mercury is precipitated by urine. We know that this fluid contains the muriated ammonia and the oxalic acid, which may alter in some measure the nature of the precipitate. It is certainly milder, since these authors admit that it may be given from six to ten grains, and is then a cathartic.

The *sal sedativus mercurialis* is another modern preparation; not, we suspect, of superior value, since its authors wish to confine it to external use. The nitrated mercury is precipitated by a solution of borax; and the salt, which is at first yellow, by the access of air becomes greenish. It is scarcely soluble in watery fluids, and when sublimed is of an orange colour. *Journal de Physique*, ix. 343. x. 411.

The union of mercury with the benzoic acid (*mercurius benzoinus*) was first mentioned, we believe, by Tromsdorf in his Chemical Annals for 1790. The flowers of Benjamin, dissolved in water, are employed to precipitate nitrated mercury. The salt is of a brown colour; but, carefully washed and dried, is white and shining, unchanged in the air, with difficulty dissolved in water, somewhat more readily in spirit of wine. It is with some regret we add, that, except its author, the only authority we can find for its having been advantageously employed is the suspicious one of M. Mittie.

The MERCURIAL SALTS offer some facts and preparations of curiosity, if not of importance. Lavoisier and Cornette, in the Memoirs of Medicine, have informed us that the mild alkalis will dissolve the calces of mercury; and Quercetanus long since de-

scribed the preparation of a *spiritus mercurialis*, which consisted of an alkaline solution of mercury; and Ritter speaks with commendation of an *essentia mercurii*, which contained the metal, joined with a caustic alkali. The neutral salts, however, have a greater power, and the most active of these is the muriated ammonia. The *mercurial tincture of Garaye* is prepared by triturating the dry sal ammoniac with mercury, suffering it to deliquesce, then again drying, and repeatedly triturating, deliquescing, and drying it. The process is shortened by triturating the brown or the red precipitate with the salt, and then subliming it.

Monnet and Paecken long since informed us, that mercury triturated with cream of tartar would be completely united with it; and if some syrup was added, the union would be so complete, that the addition of powders capable of absorbing the moisture would not affect it. Cream of tartar, though it does not dissolve the metal in its shining state, will dissolve its calces; and we once saw salivation induced, by digesting in cold water *Æthiops mineral*, sulphur, and cream of tartar, and giving the solution. If a little borax or sedative salt is added, the union will be more complete. This preparation, called *mercurius*, and sometimes *Æthiops tartarizatus*, and dissolved in water, the *eau vegetable mercurielle*, is considered as a very useful medicine, but it seems to have no claim to any extraordinary powers. The pure acid of tartar, as we are informed by Meyer and De Morveau, dissolves the mercury more readily, and in a larger proportion.

Rhenish wine, cyder, verjuice, and vinegar, have been employed as solvents of mercury. The *liqueur fondante* of Diennert, the *hydrargyrum acetatum*, and the *terra foliata mercurialis* of De Fourcy, are preparations of this kind; but the acid dissolves only the calces of mercury, and the preparations differ in activity according to the calx employed.

We find, in the works of foreign surgeons, very caustic topical remedies resulting from the union of mercury with the nitrous acid. Of this kind are the *liquor exfoliatus Bellostii*, *liquor mercurii vivi* of Mynsicht, and the *aqua grisea* of the Wirtemberg Pharmacopœia. The *mercurius nitrosus* of Selle forms white crystals, prepared by dissolving mercury in the nitrous acid. These are dissolved in four times their weight of water, and two drops of the solution are given morning and evening.

The muriated mercury is the foundation of the different mercurial waters employed externally. Iforstius's *aqua mercurialis pro scabiosis* contains equal parts of corrosive sublimate and euphorbium, with a larger proportion of arsenic than his menstruum will dissolve. Grunlingius's *linimentum ad serpiginem* consists of sublimate and alum, of each half a dram, and an ounce of gum tragacanth, dissolved in plantain water. We may here remark that alum is often useful in itch, and is an active ingredient in many of the secret remedies which profess to cure it in a very short time. Zwelfer adds to his *aqua mercurialis* a portion of aloes for venereal ulcers and cutaneous eruptions; and Jungken, in a similar water, adds ceruse, alum, nitre, sal ammoniac, vinegar of litharge, &c. A preparation nearly of the same kind occurs in the Wirtemberg Pharmacopœia, which was, for many years, the standard pharmaceutical work of Germany; but, more scientific-

VOL. I.

cally combined, Vogler's *liquor mundificans* contains the sublimate, with dock root, brown flowers, the leaves of juniper and savine, and the root of the acorus calamus. The most singular external preparation of this is the *oil of mercury*, for warts and corns, of Fausius; an equal quantity of candied sugar and of sublimate, with a very small proportion of filings of iron, are exposed first to a gentle and then a violent heat in close vessels. The iron, however, in part, decomposes the muriated mercury.

Such are the most curious or important preparations of mercury, not admitted into our pharmacopœias; but we cannot conclude this account of external mercurial applications, without guarding the more inexperienced practitioner from too free and indiscriminate employment of them. The records of medicine are full of the most dreadful instances of death, in its most painful shape, following their use; and, though the subject led us to enumerate and explain the principles of their several combinations, we have carefully avoided those particulars which would lead, on the one hand, to rash empiricism, or add to the already too numerous list of quack medicines.

As a medicine, there is scarcely an indication that mercury cannot supply. There is no more certain and active emetic than the *mercurius vitriolatus*; a more powerful laxative than the calomel; a more effectual and steady diaphoretic and stimulant than the *mercurius muriatus*; a more certain emmenagogue than calomel; a more effective errhine than the turpeth mineral; a more infallible sialogogue than either of its preparations. If we look at the principle by which these different changes are effected, we shall find it to be a steady and permanent stimulus. When applied to the extremities of the excretory ducts, it excites the action of the various glands; when, on the contrary, it is determined from the mass of blood to the first branches of the glandular system, it is equally powerful. When no glandular system intervenes, it excites the action of the extreme vessels over the whole body.

We have had frequent occasion to remark, that all the metals possess a tonic power. We shall find that in this class of medicines there are many which seem to act chiefly by lessening irritability: there are some that produce tonic effects by their stimulus on the arterial system: others that more imperceptibly increase the general powers of the whole body. In the second class mercury must be arranged, and iron seems to unite the second and third: copper, arsenic, and probably silver, belong exclusively to the third.

While, then, mercury acts as a general stimulus, it seems to unite the tonic power of the other metals; and, from these considerations, all its powers may be explained. We mean not to prejudge the question of its anti-venereal influence: when we consider this subject we shall find some arguments in favour of its specific power. Yet we may now remark, that the effects just mentioned will in a great measure explain the changes it produces; and, though a specific power appears probable, it is scarcely necessary. We shall begin, however, with cutaneous diseases, as these are most nearly connected with the principle we are endeavouring to lay down.

We took an early opportunity of observing, that we can seldom, in any instance, demonstrate any taint in

A a

the general mass; yet we added, that what appears in the secreted fluids must have been virtually, and perhaps formally, contained in it. The powers of nature separate these impure portions, and determine them to the most ready and extensive outlets, the urine and the skin; generally the latter. The constitutions most subject to chronic, cutaneous diseases, are distinguished by a general languor in the circulation: those subject to the acute kind, by an irregular determination to the surface. The former are our present subject; and we may add, that the obstructions appear on the skin, in the glandular system, or in the parts where, from the distance from the heart, its action has less power in consequence of this languor. If the circulation is properly supported, the matter is carried through the extreme vessels; if irregularly hurried, the depositions are more frequent and numerous. This position we shall have frequent opportunities of illustrating, particularly in considering the eruptions of variola. By the steady, uniform, increased action, excited by mercurials, the vessels obstructed in lepra and some similar diseases, regain their powers and throw off the accumulated masses: the same increased action prevents their recurring. Nor is this merely hypothetical; for one of the first effects of mercurials in these cases is to increase the eruption; in fact, to determine more copiously to the skin to throw off the offending matter. One difficulty indeed remains. If these humours possessed an assimilating power, the cause of their increase would continue, *perhaps*, in proportion to their evacuation. The general causes of cutaneous eruptions are not, however, of this kind; and the subject of syphilitic eruptions we reserve. When mercury has removed the more common species, a return must be guarded against. The matter seems to accumulate in spite of the powers of nature; and, as the continuance of mercurials would be inconvenient, less active medicines prevent a disease which they would not cure; and the saline or sulphureous mineral waters, sea water, or even laxative doses of salts, with a mild diet, will succeed. We need only add, that, though mercurials are alone sufficient, the addition of antimonials to assist their determination to the skin is eminently useful.

This enquiry, though it has detained us, will facilitate our future progress. Scrofula unites the cutaneous complaints with the common obstructions; and, in this case also, mercurials joined with, or followed, by neutral salts, are particularly useful; and in our account of the effects of remedies, see SCROFULA, we have hinted at the origin of the disease: a languor and want of irritability in the vessels. In gutta serena, indolent tumours of the viscera, particularly of the liver, in jaundice, constipation, and many obstructions, it is obvious that mercury must be useful on the same principle. In chronic inflammations of the liver, its action is particularly elucidated by a singular fact, the disease seldom yielding till the gums are affected by the mercurial; in other words, till the irritability of the vascular system is excited. Its use in old quartans seems owing to its influence on infarctions of the viscera; and in various dropsies independent of its evacuating powers, it is probably salutary by the same effects. In amenorrhœa this action is peculiarly striking, since it is useful only in those languid irritable habits which we have been used to call phlegma-

tic and cachectic. In melancholy, the viscera are commonly affected, and support a disease which other causes originally produced; and mercury is sometimes a very useful remedy. In chronic rheumatisms the inactive state of the vessels is sufficiently obvious, and mercurials are singularly useful.

One other class of diseases remains, *viz.* the spasmodic, as trismus, tetanus, and hydrophobia. On these subjects we can scarcely at present speak, but must refer to what we have said on the subject of '*irregular action*,' as the effect of debility. The whole will be illustrated under the articles CONVULSIONS and FEVERS, *q. v.* But, if this idea be for a time admitted, the utility of mercury will be obvious, and experience has already established the fact. If useful in the croup, it is on the same principle; and the proof is the same as that adduced in speaking of its advantages in infarcted liver: the complaint does not yield till we find proofs of the irritability of the vascular system being restored.

As an errhine and a sialogogue, (we now allude to the topical application of calomel,) it seems to act as a local stimulus only. As a sudorific and diuretic, it seldom acts without some assisting medicine more directly pointing to the different organs, and seems only to support the general action while the peculiar stimulus is supplied by the other ingredient of the formula. In general, its action in every disease is assisted by the medicines more peculiarly appropriated to it.

It is improper in weak exhausted patients, and in erysipelatous ulcers, cancers, and some similar complaints. Among its bad effects may be mentioned, excessive debility and irritability, decayed teeth, weakened stomach and intestines; but, above all, what is styled by Mr. Pearson, erythismus. It is a state of debility, with the powers of circulation exhausted, perhaps, by too long or constant exercise; a slight exertion proves fatal, seemingly from a defect of circulation in the brain.

Of the choice of the preparations we have little to add. The most useful errhine and emetic is the mercurius vitriolatus: the most effectual laxative, calomel: the most serviceable alterative, muriat of mercury. It is this preparation that gives efficacy to the popular alteratives styled vegetable; and the contrivers hope to elude detection by the density and the colour of the preparation. The metal may, however, be discovered by inspissating a large quantity, and adding ammonia. In this state the mercury will, by rubbing, whiten bright copper: in the minute proportion employed it eludes every other test.

In venereal complaints, the mercurius calcinatus or calomel are the most effectual preparations; but perhaps the mercurial ointment, rubbed in externally, is still better. In internal visceral obstructions; and in external indolent tumours, (scrofulous ones excepted,) the ointment is the best remedy: in chronic rheumatisms the calomel has been preferred: in enlargements of the prostatae, and similar indurations internally, the corrosive sublimate.

It hath been swallowed crude, as an universal remedy.

Dr. Dover and Dr. Cheney commend it in the following disorders:

"1. Joined with the gum guaiacum and a little aloes.

it hath been successfully used in the erysipelas, gout, and defœcations of the skin.

"2. In hysteric complaints its advantages are considerable, if joined with the bark, valerian, aloetic, or the gum pills, as circumstances may require.

"3. In conjunction with preparations of iron, it succeeds in suppression of the menses.

"4. In intermittents it avails when joined with the bark and iron.

"5. In ophthalmies it hath been effectual when accompanied with millepedes and laxatives.

"6. The hydrargyrus cum cretâ, joined with gum guaiacum and the antimonial wine, does wonders in chronic rheumatisms.

"7. In the jaundice, sciatica, and anasarca dropsy, the hydrargyrus cum cretâ is successful to admiration."

And to these of Dr. Cheney may be added, that old foul ulcers are sometimes brought to digest by its use.

"The hard bellies of children are relieved by it, if accompanied with such other medicaments as the particular case may require.

"By boiling two or three ounces of quicksilver in four pints of water to two pints, and using the clear liquor for common drink, it destroys worms.

"And in the venereal disease it is by many considered as a specific.

"The true secret of curing diseases with mercury is to cause it to circulate with the blood as long as possible, without producing any evacuation at all.

"A long use of quicksilver weakens the habit, and so should be accompanied with mild antimonials, the bark, or sarsaparilla, &c. as circumstances seem most to require."

Quicksilver is divided by earthy powders, balsams, mucilages, &c.; but with nothing more advantageously than the mucilage of gum arabic. Mr. Plenck, of Vienna, directs a drachm of it to be mixed with two drachms of gum arabic in powder, by degrees to add a little water, and to continue the trituration of them together until the globules totally disappear. This is called MERCURIAL MUCILAGE; to which half an ounce of any syrup, and half a pint of water may be added, and two common spoonfuls of the mixture may be taken every night and morning in such cases as require its use.

Gum arabic is supposed to powerfully restrain the mercury from running off by the salivary glands; and if a salivation is already excited, it may assist, like any other mucilaginous substance, in checking it.

Crude quicksilver in general is of equal advantage with any of its preparations; yet, in particular constitutions, one or other of them may demand a preference.

ARGENTUM MO'BILE, et FUSUM. See ARGENTUM VIVUM.

ARGENTUM NI'TRATUM. See ARGENTUM.

ARGILLA, one of the earths, the basis of alum; and, in the modern nomenclature, styled ALUMINE. It is soft, mild, and insoluble; and is considered as possessing no medicinal powers; but the various earths, the TERRE SIGILLATÆ of older authors, so called because they were impressed with a seal, seem to be only pure clay, and owe their demulcent, and apparently astringent, powers to this earth alone. See BOLUS.

ARGI'LLA A'LBÄ, ARGI'LLA CAN'DIDA, (from *αργος*, white). See CIMOLIA ALBA TERRA.

ARGISTA'TA, (from *αργος*, white). Incorporated with wax.

A'RGOL. See TARTARUM.

A'RGUS. The name of a sort of pheasant. ΠΗΛΙΑΝΟΣ.

ARGYRI'TIS, (from *αργυρος*, silver). See LYTHARGYRUM and LYTHARGYRUS ARGENTEUS.

ARGYROPŒIA, (from *αργυρος*, silver, and *ποιεω*, facio). The art of making silver out of more imperfect metals.

ARGY'RUS, (from *αργος*, white). See ARGENTUM.

ARGYROLIBA'NUS, the WHITE OLIBANUM, *q. v.*

ARGYROTROPHE'MA, (from *αργος*, white, and *τροφημα*, food). A cooling food made with milk.

ARHEUMATI'STOS, (from *α*, neg. and *ρευματιζομαι*, to be afflicted with rheums). An epithet given to the external parts, particularly the joints, while free from gouty depositions.

A'RI. See MONOPIA.

A'RIA, (from *αρειω*, to knit together,) so called, because its branches interweave with each other. The WHITE BOAM, or WILD SERVICE TREE. Called also, *chamæmespilus*; *cratægus aria* Lin. Sp. Pl. 681. It grows in woods upon rocky mountains, and flowers in April. The fruit mitigates coughs and promotes expectoration. Dale.

A'RIA-BEPOU. See AZEDARACH.

ARICY'MON, (from *αρι*, quickly, and *νωω*, to impregnate,) also ENARICY'MON, (from the same, adding the *εν*). These are terms applied to a fertile woman, who soon conceives, and is quickly impregnated.

A'RIDA MEDICAMENTA, (from *areo*, to dry up). DRY MEDICINES, such as powders.

ARI'DITAS CO'RPORIS, (from *aridus*, dry). See MARASMUS.

ARI'DULLAM, a substance used in the East Indies as a remedy in intermittent fevers; seemingly containing ARSENIC. *q. v.*

ARI'DURA, (from the same). A WASTING or LEANNESS with an apparent want of moisture, as in hectic or consumptive habits; or the withering of a particular part, as a limb.

ARI'LLA, (from *arum*, a grape). A GRAPE STONE.

ARILLA'TUS, (from *arillus*, the outward coat of a seed). In botany it means covered with an arillus or outward coat of a seed.

ARIMA'SPES. See MONOPIA.

A'RIS. The name of an instrument used by the ancient, and also of an herb.

ARISTALTHÆ'A, (from *αριστος*, good, and *αλθαία*, althæa). See ALTHÆA.

ARISTIO'NIS MACHINAME'NTUM. A machine for restoring luxations, invented by Aristion.

ARISTOLOCHI'A, (from *αριστος*, optimum, and *λοχεια*, purgamenta post partum in utero relictæ). BIRTHWORT. It is so called, because esteemed for promoting the lochia in child-bed women. Also called *admiriza*.

There are several species of this plant, natives of the southern parts of Europe, whence we are supplied with the dry roots. Most of them bear the cold of this climate. The roots of all the kinds are acrid and bitter.

and their smell nauseous: they give out their virtues both to water and to spirit; but to the latter most perfectly. They hurt, however, the appetite and produce a languor in weakly constitutions. The virtues are nearly similar, except the *a. serpentaria*; though Dr. Alston of Edinburgh thinks that the roots of the creeping sort are the best. The doses are from gr. v. to ʒi.

ARISTOLOCHIA TE'NUIS, vel CLEMATITIS. CREEPING BIRTH-WORT. Also called BUSHY-ROOTED or SLENDER BIRTH-WORT. *Aristolochia clematidis* Lin. Sp. Pl. 1364.

This root has been considered as a powerful deobstruent, particularly of the uterine system, and a warm stimulant. Dr. Alston thinks it equal to the Virginian snake root for all the purposes in which it is used. Dr. Cullen says it has been esteemed for its emmenagogue virtues; and in some cases of retention and chlorosis, as a warm and stimulating medicine, he has found it useful; but never in cases of suppression. It has been long commended as a cure for the gout, making a considerable part of the Portland powder, and has often been employed by itself in the same manner as that powder, to be taken every day for a great length of time. It has the same power of preventing fits of the gout, and commonly with the same consequences. Cullen's Mat. Med.

ARISTOLOCHIA LO'NGA, et ROTUNDA, Lin. Sp. Pl. 1364. ROUND and LONG ROOTED BIRTH-WORT; called also *aristolochia mascula*.

ARISTOLOCHIA ANGUICIDA, Lin. Sp. Pl. 1362. The taste of this species is highly nauseous, and is employed against the bites of serpents by pouring the juice into the wound.

ARISTOLOCHIA ODORATISSIMA, Lin. Sp. Pl. 1362. The smell of this species is more pleasing, but it scarcely possesses any virtues.

ARISTOLOCHIA SERPENTARIA, Lin. Sp. Pl. 1363. See SERPENTARIA.

ARISTOLOCHIA ROTUNDA CONCAVA. See MOSCHATELLINA.

ARISTON, (from *αρισταιν*, to dine). Also *frandium*, DINNER.

ARISTON MAGNUM et PARVUM. Avicenna says they are remedies against a phthisis, when attended with a fever.

ARLADA, or ARLADAR. See REALGAR.

ARM, the part of the upper extremity between the shoulder and the wrist.

ARM PRESENTATION; in labours when this part of the child comes foremost. In this case it is very generally necessary to turn the children. See LABOURS.

ARMALA. See RUTA.

ARMA'LGOL. See CORALLIUM.

ARMARUM UNGUENTUM, an ointment employed to anoint the weapon with which a wound was made. A mode, according to the doctrines of *sympathetic medicine*, which would cure the wound. Dryden, in his alteration of the Tempest, has gravely introduced this ridiculous fancy; but Dryden believed also in astrology.

ARMATU'RA. See AMNION.

A'RME, (from *αρω*, to adopt). A coalition of wounds, also the joining of the sutures of the head.

A'RMENA, (from *armor*, to be furnished). An in-

strument with all the apparatus for any work in which we are engaged.

A'RMENIACA MA'LA, (brought from Armenia,) called also *præcocia*. The APRICOT TREE. Theophrastus calls it *persea* to distinguish it from the peach; it was afterwards called *persea-præcox*. The Latins called it *præcoqua*, from which the latter Greeks formed their *bericocca*, and the French the word *abricots*. See ALIMENT.

This fruit is rather dietetic than medicinal: of the kernels in the stones is made ratafia; they resemble bitter almonds, and contain probably the Prussic acid.

AR'MENUS LAPIS; also called *lapis Armenius*, *azutum ceruleum fossile*. The ARMENIAN STONE.

It is a copper ore of a pale blue colour. It operates instantly as an emetic in a dose of four grains, and is not essentially different from the lapis lazuli.

ARMI'LLA, a BRACELET. The round ligament that confines the tendons of the carpus.

ARMONIACUM. See AMMONIACUM.

ARMORA'CIA, (Armorica, the place from whence it was brought). WATER RADISH. See SISYMBRIUM. Also WILD RADISH and HORSE RADISH. See RAPHANUS RUSTICAN.

A'RNABO. See ZEDOARIA.

ARNA'LDIA, (from *αρς*, a lamb, and *αλδος*, for *αλγος*, pain). It is so called because lambs are subject to it. A malignant slow disease of the chronical kind, attended with an alopecia; it was formerly very common in England.

A'RNICA MONTA'NA, (from *αρς*, a lamb,) so called from the likeness of its leaves to the coat of a lamb. GERMAN LEOPARD'S BANE; called also *doronicum*, *alisma*, *doronicum plantaginis folio*, *caltha alpina*, *acyrus*; *panacea lapsorum*. It is the *arnica montana* Lin. Sp. Pl. 1245. Nat. ord. *Composita discoidea Corymbifera* of Jussieu. Roots and flowers. This plant grows particularly in Germany, and flowers throughout the summer. The leaves and flowers have a sharp, aromatic, bitterish, taste; and, when bruised, their odour provokes sneezing. Water and rectified spirit extract their virtues by infusion, and retain them in distillation. The roots are more aromatic, though their active matter is somewhat less volatile. Bergius considers this plant as emetic, errhine, diuretic, diaphoretic, and emmenagogue. From its supposed power of attenuating the blood, it has been esteemed peculiarly efficacious in obviating the bad consequences occasioned by falls and bruises, and hence acquired the title of PANACEA LAPSORUM. Dr. Colin has written a work on this subject, *De Arnica in Febribus, et allis Morbis Putridis*; in which he highly extols its febrifuge and antiseptic virtue. Dr. Bruckner recommends a decoction of the arnica in fevers attended with hæmorrhages, efflorescences, &c. Lewis and Neuman speak highly of its power. In fevers of the putrid and intermittent kind, both the flowers made into an electuary and their watery extract have been successful. In putridity and debility, malignant dysenteries, rheumatism, gangrene, palsy, and gutta serena, it is said to have manifested considerable efficacy. Nine drachms of the flowers powdered and mixed with a proper quantity of honey into an electuary, is the dose to be taken in two days. Or one ounce of the flowers infused in a sufficient quantity of

boiling water for half an hour, and afterwards, in a vessel closely stopped, boiled for a quarter of an hour. Of this decoction two ounces were taken every two hours. Or, two ounces of the root in powder were digested with thirty ounces of water in a phial closely stopped, and placed deep in a sand bath, for twelve hours, and this sweetened with syrup of marshmallows, of which two or three ounces were taken every two or three hours. The root, given from five to ten grains, is said to be useful in diarrhœas and dysenteries, in gangrenes, quartans, and typhi. Externally it is applied to foul ulcers and gangrenes. It is much extolled in Germany, though not much used in England; however, it certainly merits attention. The flowers of the *inula dysenterica*, *anthesis tinctoria*, *hypocæris radicata*, and other flosculous flowers, greatly resemble, and may be mistaken for those of the *arnica*.

ARNOGLO'SSUM, (from *αἶψα*, a lamb, and *γλῶσσα*, a tongue,) from the likeness of its leaf to a lamb's tongue. See *PLANTAGO LATIFOLIA*.

ARNO'TTO, (Spanish). See *ORLEANA*.

ARNOTTS, the roots of a plant, frequently turned up in plowing. They are farinaceous, and resemble a chesnut when roasted. They seem to be the roots of a species of *bunium*.

A'ROHOT. See *ARGENTUM VIVUM*.

AROMA, (from *αῖρι*, intensely, and *ὀσφω*, to smell). Any thing fragrant or odorous; sometimes it is taken for myrrh. The aroma of plants is probably an essential oil, highly volatile, and with the greatest difficulty preserved by distillation. The exquisite perfume styled the attar (oil) of roses, we are taught how to prepare in one of the early volumes of the Asiatic Researches: other delicate perfumes, united with inodorous oils, are in that state preserved by combining them with alcohol by a very gentle heat. The ancient chemists, however, designated by this title the peculiar discriminated odour which belongs to each individual, and perhaps to every body in the universe; and they applied this to medicine by endeavouring to extract the odour, which they styled the quintessence: we need not say with little real advantage.

ARO'MA GERMANICUM. See *ENULA*.

ARO'MA PHILOSOPHO'RUM. See *CROCUS*. This term also implies a preparation of Paracelsus, styled *AROPH*, consisting of flowers from lapis hæmatites and sal ammoniac sublimed together. It forms a medicine recommended in quartans, and in the *plica Polonica*.

AROMA'TICA, (from *αρωμα*, an odour). Aromatics, or *spicy* drugs, are of a warm pungent taste, with more or less of a fragrant smell; some are purely aromatic, as cinnamon, nutmegs, &c.; others have a sweetness mixed with them, as in the angelica root, aniseed, &c.: some have an astringency, as cinnamon; others a mucilage, as the cassia lignea, &c.; some a bitterness, as orange peel; and others are also bitter and astringent, as the bark.

The several medicinal virtues of these mixed aromatics are extracted by the same means as from those which are less compounded; thus the aromatic part of lemon peel rises in distillation with water, whilst the bitter remains behind in the extract. The aromatic matters contained in different subjects differ much in

their pharmaceutic properties. The virtues of all aromatics are extracted by *sp. vini rect.*; water extracts a portion from some, but from many none.

In distillation they rise with water more perfectly than with spirit, though in some few instances the aromatic matter wholly rises in distillation, both with spirit and with water, as that of lemon peel, whilst pepper still retains part of its aromatic matter, though distilled with water. In the essential oil and resinous part of aromatics all their peculiar qualities reside. The more essential oil any vegetable affords, the weaker the oil is, and *vice versa*.

Aromatics warm the stomach, and by degrees the whole body, hence are useful where the vital heat is below the standard of health; they promote the natural secretions, they resist putrefaction, and are almost essential to the health in hot climates, where they are so plentifully produced.

AROMA'TICA AQUA. See *PIPER JAMAICENSE*.

AROMA'TICA NUX. See *NUX, MOSCHATA*.

AROMA'TICA PUL'VIS. See *AROMATICÆ SPECIES*.

AROMA'TICA TI'NCTURA COMPO'SITA. See *CINNAMOMUM*.

AROMA'TICA. CONFE'CTIO AROMA'TICA. See *CONFECTIO*.

AROMA'TICÆ PILULÆ. AROMATIC PILLS. These consisted of aromatics with guaiacum and aloes. In small doses, of fifteen or twenty grains, they warm the stomach, by degrees the whole habit, and are also gently aperient. They were formerly called *diambræ pilulæ*.

The College of Physicians of London have substituted a composition, called *PULVIS ALOETICUS cum GUAIACO*—*aloetic powder with guaiacum*. In this, three parts of aloes are added to two of guaiacum and one of aromatics.

AROMA'TICÆ SPECIES, NOW PULVIS AROMATICUS. The AROMATIC POWDER consists of cinnamon two ounces, the lesser cardamoms freed from their husks, ginger, and long pepper, of each one ounce. It is an improvement of the *diambræ sine odoratis species*.

AROMA'TICUM LI'GNUM. See *CANELLA ALBA*.

AROMATICUM ROSA'TUM. ROSE SPICE. An aromatic powder, formerly kept in the shops, in which roses were a part of the composition.

AROMA'TICUS, CO'RTEX. See *CANELLA ALBA*.

AROMATOPO'LA, (from *αρωμα*, and *πωλεω*, vendo,) a druggist, a vender of drugs and spices.

A'RON. See *ARUM*.

A'ROPH. See *CROCUS*. Also a name which Paracelsus gave to the flowers raised by sublimation from lapis hæmat. and often used by him as a *lithontriptic*.

ARQUATUS MORBUS. The same as *ASCERTUS MORBUS*. See *ICTERUS*.

ARQUEBUSA'DE, (from *arqebuse*, a hand gun,) so called because it is used as a vulnerary in gun shot wounds. It is the name of a water which is also called *aqua vulneraria*, *aqua sclopetaria*, and *aqua catapulta-rum*. See *AQUA*.

A'RRAC. (Indian.) See *ORYZA*, and *PALMA COC-CIFERA*.

A'RRACHE. See *ATRIPLEX*.

A'RRAPHON, (from *α*, priv. and *ἴσφν*, sutura,

**WITHOUT SUTURE.** The word is applied to the cranium when apparently without sutures.

**ARRHŒ'A,** (from *α*, priv. and *ῥέω*, to flow). The stoppage of a flux: and by Hippocrates appropriated to the suppression of the menses.

**ARRHO'STIA,** (from *α*, priv. and *ῥάω*, to strengthen). INFIRMITY, ILL HEALTH.

**ARSAL'TOS.** See BITUMEN.

**ARSA'TUM.** See FUROR UTERINUS.

**ARSE'NIAS ARSE'NIATE.** ARSENICAL SALT, formed by the union of the arsenical acid with certain bases.

**ARSE'NICUM A'LBUM,** (from the Arabic term, ARSANEK; or from *αρσεν* for *αγεν*, *masculus fortis*, because of its strong and deadly powers,) called *crystallinum*, *risagallum*, *aquala*, *arfar*, *aquila*, *zarnick*, *artaneck*, WHITE ARSENIC, and RAT'S BANE.

Arsenic is a semi-metal contained in almost every ore, particularly those of tin, bismuth, the white pyrites, and *cobalt*, see COBALTUM; from the last the greatest quantity is obtained: the ore of the cobalt being broken in pieces is placed over a fire, and the arsenic sublimed from it; which, resting on the sides of long chimneys designed for its reception, is swept off into proper vessels to be re-sublimed, or at least melted, by which it is formed into the shining masses which are met with in the shops: those of the greatest solidity and brilliancy should be preferred.

To England it is chiefly brought from the mines in Transylvania, Saxony, Hesse, and Bohemia. Some small quantities are sublimed in Cornwall from the cobalt that is found there. Large portions of sulphur render it inert. It is soluble in eighty parts of water at 60°, and in 15 at 212. When treated with nitrous acid it becomes the arsenical acid, which is reduced immediately if heated in a glass tube with any fatty or carbonaceous matter.

The pure white arsenic hath a penetrating corrosive taste, sublimes at 283° of Fahrenheit, and taken into the body is a violent poison; it produces speedy dryness in the throat, and inflammation, dejection, fainting, stupor, delirium, tremors, convulsions, palsy, thirst, burning in the stomach, gripes, vomiting, cold sweats, hiccoughing, and at last death. Besides the effects which it hath in common with other poisons, it quickly destroys the coats of the stomach, and perforates the intestines, occasioning a swelling and sphacelation of the whole body, and a sudden putrefaction after death.

When the quantity taken is not fatal, it occasions tremors, palsies, or lingering hectic.

Though there is but little hope after this poison is swallowed in any considerable quantity, yet, if assistance is to be had, a scruple of the white vitriol will excite a vomiting very quickly, and the metal may be evacuated, though imperfectly, from its weight; and so deleterious is its nature, that a very small remaining portion will soon be fatal. It is proper, therefore, to inviscate what remains; and, for this purpose, warm water, with a large proportion of sweet oil, or milk with sweet oil, should be given to support the vomiting; after sufficient vomiting, mucilages and demulcents, particularly gum arabic, in large quantities, new milk

and oil, with fat broth, should be continued some time, and the bowels must be kept lax.

We have not much reason to triumph in our success from these remedies. The arsenic is seldom wholly discharged; and if the patient's life is preserved, he drags on a miserable existence, weak, emaciated, and irritable. For these reasons counterpoisons have been industriously sought; and when it was found that sulphur blunted the activity of metals, particularly of arsenic, hepatic alkalis have been freely exhibited, both to neutralize the acid and to check the activity of the metal. The records of medicine do not, however, allow us to boast of the success of this refinement, and we shall soon investigate the reason.

The acids of lemons and apples have been highly recommended by a modern author of credit, Sage, but his plans have been followed with little success. Alkalis, though a more probable remedy, have been equally unsuccessful; but perhaps the advice of Hahneman may be more useful: he gives two quarts of warm water, in which a pound of common soap is previously dissolved, within the space of two hours.

We have no reason to think that arsenic taken into the stomach ever passes into the mass of blood; all the effects are those exclusively on the *primæ viæ*. Yet equally fatal effects have been found when this semi-metal has been breathed in smelting-houses, when sprinkled on wounds, when even worn as an amulet; and for its baleful influence in the form of vapour, we have the testimony of our own countrymen. Fothergill Medical Observations, vol. v. and Sherwin Memoirs of the Medical Society, vol. ii.

Fortunately we can ascertain the cause of the complaints induced by arsenic; for when the contents of the stomach, if given as a poison, are thrown on live coals, a garlic smell is immediately obvious. On polished copper, if heated between its plates, a white spot is impressed; or in close vessels, the arsenic itself will be found sublimed in the upper parts.

In the stomach, however, there are many substances which may resemble or disguise the smell of garlic, especially if the arsenic be in small quantities. We are therefore advised by Hahneman to boil the contents of the stomach of the person supposed to be destroyed by this poison in a large quantity of river water; to add to one-third of the filtered liquor, hot and limpid lime water; to another third, water saturated with hepatic gas; and to the remainder, a solution of copper in pure aqua ammoniæ. Each fluid is rendered turbid if the suspected contents contain arsenic, and the sediment thrown on live coals emits the odour of garlic. The sediment from the lime water is again dissolved by a recent solution of arsenic; the orange coloured sediment from the hepatic gas thrown on the coals takes fire, and the smell of sulphur is observed previous to that of the garlic; while the yellow green sediment of the copper is soluble in pure ammonia, and acids of every kind.

In reading ancient authors on the yellow and red arsenics it should be observed, that their arsenics are not the same as ours. Among the Greeks two kinds were in use, viz. the *yellow*, which we now call ORPIMENT, and AURIPIGMENT; and the *red*, which they call SAN-

**PARACA.** The Arabians had also two kinds, viz. the *yellow*, which they call *SCANDARACA*; and the *red*, which they call *REALGAR*. It was the fossil sulphurated arsenics that the ancients used medicinally, and only those which were *yellow* and *flaky*, like talc, and which alone they call *ARSENICON*. The white arsenic is a discovery of later times. The auripigment we meet with is of the yellow sort, its taste is not very acrimonious. The best mineral orpiment is brought from Turkey: it is very little, if at all, poisonous.

Our yellow and red arsenics are artificial, being no other than the white, mixed with different proportions of sulphur. The white is the strongest, the yellow weaker, and the red weakest. See *AURIPIGMENTUM* and *REALGAR*.

By the use of arsenic in these forms, the ancient physicians were not aware of its destructively stimulant powers. Yet so early as the 13th century, Theodore, a Venetian surgeon, applied it to scrofulous tumours; and, in the next century, Guido used it as a caustic to produce an eschar in scrofula; and, moistened with vinegar, it was applied afterwards not only to scrofulous tumours, but to the *spinæ pedum* (corns). It was afterwards used as an application to cancers; and, with additions of the most singular and ridiculous nature, of qualities the most opposite, it has formed the basis of many remedies for cancer and scrofula. Aruin nitre, salt of soot, quick lime, opium, aqua fortis, vinegar, ceruse, blue vitriol, the ashes of burnt (old) shoes, pulp of carrots, hemlock, and bark, are a few only of the remedies united with arsenic, either to correct its acrimony or add to its virtues. Had we room to follow this part of the subject minutely, we could trace the source of some popular remedies in authors now seldom read or known.

In the early part of the present century, when the rage for finding medicines of peculiar activity among the poisons was prevalent, arsenic began to be employed. We have not been able to trace its use in any work earlier than that of Friccius, published at Vienna in 1710; yet we suspect it was used earlier, since we are dissuaded from its use by Sparling, whose dissertation on arsenic, was published at Wirtemberg, in 1685. Since, however, the time of Friccius, though Stahl, Wedel, Boerhaave, and Storch, have violently opposed its use; though various authors have found it dangerous, inefficacious, or hurtful, the practice has continued.

It seems to have been first externally recommended in cancers, generally accompanied with opium; and it certainly produces at times a salutary change in the appearance of the sore. We have had reason to regret that this change is not permanent. Various forms have been employed for the external use of arsenic. Hahneman proposes to give it dissolved only in water, and this probably is the best method; but the dose should not exceed one-sixteenth of a grain, or rather at first it may be one-eighteenth or one-twentieth, for different constitutions are variously affected with this metal.

Mr. *Justamond's* applications to cancer, originally derived from the information of a receipt preserved in the Earl of Arundel's family, were little varied: they are generally combinations of arsenic and sulphur. The Earl of Arundel's receipt directs an ounce of yellow arsenic, with half that quantity of Armenian bole, and

sometimes as much red precipitate. He employed also a sulphuret of arsenic, and a combination of this sulphuret with crude antimony. The arsenical preparation which he preferred was scraped and laid on the middle of the sore, while the edges of the wound were moistened with a combination of muriated iron and sal ammoniac. The effects were to correct the stench, to meliorate the appearance of the sore, and to promote the separation of the entire gland.

*Miss Plunkenet's* receipt is said to consist of the leaves of the *ranunculus acris*, the greater crow foot, and the *flammula vulgaris*, the lesser crow foot, a species also of *ranunculus*: an ounce of each is to be bruised, and added to a drachm of arsenic and five scruples of sulphur. The whole is to be beaten into a paste, formed into balls and dried in the sun. When used, they are beaten up with the yolk of an egg, and applied on a piece of pig's bladder. The use of the *ranunculus* is to destroy the cuticle on which the arsenic does not act.

The *arsenicum citrinum* is one of the most active preparations of arsenic, and has often produced fatal effects. Ten parts of arsenic are sublimed with one of sulphur; and this preparation was used by Friccius, as well as white arsenic, in intermittents. To this article we may also refer the preparation recommended by Dr. Adair in the Medical Commentaries for the yaws, and other obstinate cutaneous eruptions, viz. one-eighth of a grain of arsenic triturated with sulphur.

*M. Febure's* remedy consisted of ten grains of arsenic dissolved in a pint of water, with an ounce of the extract of cicuta, three ounces of Goulard's extract, and a drachm of liquid laudanum. With this fluid the cancer is to be washed every morning. He joined arsenic internally, and directs two grains to be dissolved in a pint of water, to which must be added syrup of chicory, with rhubarb, half an ounce. A table spoonful is to be given morning and night with half a drachm of syrup of poppies. It may be remarked, that the dose of the arsenic in this preparation is one-twelfth of a grain.

The *aqua arsenici* is a deliquescent solution of the *arsenicum fixum*, formed by deflagrating the metal with nitre. This last preparation was recommended by Müller; and, disguised with the wood of red sanders and the *terra sigillata*, was used by quacks in Germany, and found highly deleterious. The solution is recommended by Hartmann, in a cancer of the nose.

The *liquor arsenici albi* is formed by deflagrating two parts of nitre, as much arsenic, and sometimes one part of sulphur. This also has been recommended in cancers; while a solution of arsenic in the muriatic acid, the *butyrum arsenici*, is only employed as a caustic.

It is unnecessary to follow the use of orpiment, the arsenic of the Greeks, the Romans, and Arabians, through the numerous authors who have spoken of it, and who have used it in a variety of diseases, assisted or directed by the medicines peculiarly adapted to them. In fact, the additional remedies were successful, for little was obtained from the metal, especially if loaded with sulphur.

Arsenic is, however, a valuable internal remedy in its appropriate dose, viz. about one-eighteenth part of a grain. We have often mentioned the tonic power of metals, and amongst these have instanced arsenic. We find a strong proof of this power when given to horses. From ten grains to half a dram given daily will bring

a horse into excellent condition, render him healthy and active, improve his appetite and the gloss of his coat. It was not, however, by such observations that quacks and mountebanks were first led to employ it. The practice was earlier than the commencement of the last century, for it is mentioned by some of the earliest authors of that era. It was not, however, exhibited alone, but with a variety of other medicines which were supposed to correct its virulence. Among these the mountain crystal, crystalline quartz, was thought most effectual in destroying its virulence; but pepper, crabs' claws, and vinegar, were also added. Fourcroy mentions its being repeatedly boiled with crystals of tartar, and afterwards crystallized; Dr. Willan and Dr. Fowler boil it with salt of tartar, Monro with pearl ashes, and Gmelin with antimonial nitre. The salt of tartar, supposed to form the arsenicated potash, we suspect does not unite with the arsenical acid; for Caels, in the Brussels Memoirs, vol. iv. found it equally fatal to rabbits, cats, and dogs; nor do we find that the stomach will bear a larger dose of this supposed metallic neutral, than of the arsenic uncombined. Macquer combines the metallic acid more effectually with potash, by melting and subliming them together.

The use of arsenic as an internal remedy for *intermittents* was first known, in consequence of the credit Edward's ague tincture obtained for their cure. This was said to be a saturated solution of the arsenic in water; but it cannot be true, as the dose then would be little less than an eighth of a grain; on the contrary, it is less than what is usually given. We used Edward's ague tincture, in 1780, in some obstinate intermittents brought from Coxheath camp, with complete success; and imitated it very soon afterwards by a solution of arsenic in common water. We can truly add, that from very long and frequent experience we never found the slightest reason to suspect it of any bad effects. We are certain that neither dropsy nor hectic was its consequence.

Dr. Fowler recommends it in intermittent pains in the head: for these the bark is often an insufficient remedy. We were led to employ it from finding it the basis of an old woman's remedy, but have not had sufficient experience of its efficacy to speak of it decisively. There are several instances in the Medical Commentaries of its utility in epilepsy.

The plasters which have arsenic for their principal ingredient are numerous: Angelus Sala has given a recipe for an *emplastrum magneticum in peste*; Crollius, an *emplastrum ex magnete arsenicali*; and the Wirtemberg college, in their Pharmacopœia in 1763, an *emplastrum magneticum arsenicale*. These were chiefly employed to bring pestilential buboes to suppuration; in obstinate putrid ulcers; as a remedy for cancers; incarcerated herniæ, and prolapsed uterus; or to cure obstinate quartans when laid on the region of the spleen. In these instances they are said to have been successful, but Feldman has recorded some fatal consequences from their application.

ARSE'NICUM FLA'VUM. ARSE'NICON. CITIRINUM, vel CROCEUM. SEE AURIPIGMENTUM.

ARSE'NICUM RU'BUM FACTI'TIUM. SEE REALGAR.

White arsenic, sublimed with one-tenth its weight of sulphur, is yellow; and with one-fifth it is red.

Both the yellow and the red fossil arsenics, when of a smooth texture, are called ZARNICUS; but when composed of small scales or leaves, they are called auripigmenta.

A'RTABA. An Egyptian measure containing about five of our pecks.

A'RTANECH, or A'RTANECK. SEE ARSENICUM ALBUM.

ARTEMISI'A; (from Ἀρtemis, Diana, because it was used in the secret disorders of women, over which she presided;) called also, *mater herbarum*, *absinthium alpinum*, *berens secum*, *parthenicum*, *cingulum sancti Johannis*, *herba regia toxitesia*, *bubastecordium*; the HEART of BUBASTUS, and COMMON MUGWORT, named by the Gauls *bricumum*. The species used by the direction of the Edinburgh college is the *artemisia vulgaris*, Lin. Sp. Plant. 1188. Nat. order *compositæ discoideæ*.

The artemisia has an aromatic smell, and a bitterish taste. It hath been highly spoken of by Hippocrates and Dioscorides as promoting the uterine evacuations; and on this account called *charistolochia*. Galen used it in form of fomentation, and it has been supposed to moderate hysteric spasms, used in infusion for common drink and in baths. The flowers and tops are the strongest; but at present this medicine is rejected by the London college.

It is a name of the BOTRYS, and ABROTANUM; which see.

ARTEMISI'A PO'NTICA, Lin. Sp. Pl. 1187. ARTEMISI'A MARITIMA, Lin. Sp. 1186. SEE ABSINTHIUM.

ARTEMISI'A ABROTANUM, Lin. Sp. 1185. ARTEMISI'A CANPESTRI'S, Lin. Sp. Pl. 1185. ARTEMISI'A DRACUNCULUS, Lin. Sp. Pl. 1189. ARTEMISI'A GLACIALIS, Lin. Sp. Pl. 1187. These species possess the virtues of the ABROTANUM, q. v.

ARTEMISI'A CHINE'NSIS, Lin. Sp. Pl. 1190. SEE MOXA.

ARTEMISIA SANTO'NICA, Lin. Sp. Pl. 1185. SEE SANTONICUM.

ARTEMISIA RUPESTRIS, Lin. Sp. Pl. 1186. This species does not greatly differ from the former, but has been thought useful in intermittents. It is the *genipi herba* of the pharmacæutists, q. v.

ARTEMONIUM, (from Ἀρtemon, its inventor). The name of a collyrium described by Galen.

ARTE'RIA, αρτηρια. AN ARTERY, (from αρ, air, and τηρω, to keep,) because the ancients supposed that only air was contained in the arterial system; but by the word artery, Hippocrates meant what is now known by the name of aspera arteria; nor were the veins distinguished from the arteries in the oldest times: for φλεῖς, among the ancients, was applied both to arteries and veins; and, indeed, some of our more modern writers use the term *vena* when speaking of the pulse.

An artery is a strong elastic ramifying tube, arising from the heart. The arteries are properly but two; they rise from the two ventricles of the heart; one of them is called AORTA, which see: the other is named the PULMONARY ARTERY, for it springs from the right ventricle of the heart, and is wholly confined to the lungs. SEE PULMONES.

The figure of an artery somewhat resembles a tree; the smaller ramifications of the arteries frequently ana-

anastomose with each other, as may be observed in the coats of an intestine when they are injected. The largest appearance of this kind is in the vertebral arteries, which unite in the skull. The use of the anastomosis is to keep up an equal circulation, and to prevent the bad effects of partial obstruction.

It is generally said that the arteries are of three kinds, viz. the sanguine, which circulate red blood; the serous, through which serum only is naturally conveyed; and the lymphatic, whose contents are lymph: it is also said, that if the blood is pushed into serous vessels, it is there obstructed, and produces inflammation. In reality, however, they are all the same tube continued, which gradually divides into branches, and these branches grow smaller the further they are from the heart. Near to the heart the thicker blood circulates; the force of the circulation is there stronger; and far from the heart the circulation lessens in its vigour, so the thinner fluids are only conveyed in the smaller branches. But if by exercise, or other means, the heat of our bodies is increased, the circulation is pushed forward, the red blood and other orders of thinner fluids can proceed to where still thinner fluids only circulated before; for the smaller vessels can descend to the capacity required by a more active circulation, and contract again to their former dimensions when the distending force is removed.

Arteries terminate three ways; the most common is into veins. Harvey discovered, or demonstrated, the circulation of the blood; but Malpighius first observed, that the last branches of an artery, running into minute divisions, dispose themselves on a membrane as on a firm base, and there open into one another by the mutual intercourse of small canals; he first traced out these canals, through numerous mazes and windings, through which they convey the blood; but here the small branches, disposed with great nicety, extend over equal spaces, and destitute of lateral shoots, as being no longer subdivided, constitute the origins of the veins and lymphæducts, with their sinuses. There are, however, many reasons to believe that the arteries and veins do not form continuous canals, but that some minute follicles are interposed. When the action of the minuter arteries is increased, as in blushing, the veins do not swell, and the pulsation of the former is lost before the vein commences; nor, in any injection, is the wax continued unbroken, from the extremity of the artery to the commencement of the vein.

The next termination of arteries is into little cavities or sinuses, as in the corpora cavernosa penis; the last is into excretory ducts.

The arteries generally lie deep, and always run on the inflected side of the limb, as in the axilla, and the inner part of the cubit: this situation prevents their being either too much stretched or compressed in the various motions of the body.

In the beginning of each of the large arteries before mentioned, there are three valves, which appear like purses, and prevent the return of the blood to the heart (see *COR*); the other parts of the arteries are free from valves.

The coats of the arteries are three. 1. The *EXTERNAL*, containing a great number of blood vessels: many nerves run through it; it is elastic; and its fibres run in every direction.

2. The *MIDDLE* is composed of fibres which are disposed circularly, and nearly parallel to each other.

3. The *INTERNAL* is a thin membrane, whose surface is very smooth, to give an easy passage to the blood.

Notwithstanding the disputes which have occurred among anatomists relative to the substance of these coats, it is pretty well understood that they are formed of muscular fibres and elastic ligaments, the inner being membranous and remarkably strong; and that the muscular fibres themselves are probably possessed of elasticity, as well as the ligament. The muscular fibres of the smaller arteries are in proportion more numerous than of the larger; since in Dr. Hunter's experiment of bleeding a horse to death, the aorta was contracted only one-twentieth of its natural area, and the radial one-half. The experiment is not indeed conclusive, because in the article of death, the blood is not propelled to the small ramifications. In a certain degree, however, the fact is true; and the object of this structure is, to support the circulation at a distance from the original source of motion.

The cellular membrane is improperly numbered among the coats of the arteries, for it only connects the real ones.

The nearer to the origin, the weaker are the arterial coats; whence the frequency of aneurisms in the beginning of the aorta.

Arteries are sometimes found of a serpentine form; but they are not so in a natural state of health, except during particular actions, and then they recover their original state as soon as the temporary cause is removed. This cause is the dilatation: the coats are elastic, therefore, whatever distends them must at the same time lengthen them, and thereby produce serpentine turns. This frequently happens in injecting the arteries of dead bodies: in the viper it is very apparent in an artery which runs along the outside of its lungs; every time that the heart beats, this artery is seen in a serpentine form. The arteries of the uterus are more convoluted in the last months of pregnancy than they were before conception; so far is the common observation from being true, that the uterine arteries have naturally a serpentine course to admit of the enlargement of that organ in pregnancy, without stretching the arteries.

The arteries are liable to ossification, particularly the iliac and crural; this happens where an amputation is performed: a caustic is necessary. The ossification begins in the internal membrane, which first thickens, then ossifies in distinct centres till these, enlarging, unite, and the whole becomes bone. This disorder afterwards extends to the outer coats, and a mortification is generally the consequence. See *MORTIFICATION*.

The particular arteries may be seen under their respective names, but we shall here describe their general course. From the right ventricle of the heart arises the *PULMONARY ARTERY*, which is wholly distributed in the lungs.

The *AORTA* arises from the left ventricle of the heart, and immediately sends off the *CORONARY ARTERIES* into the heart and its auricles. From the upper part of the arch of the aorta rise the *CAROTIDS*, which supply the head.

Near the carotids rise the *SUBCLAVIAN ARTERIES*, which send off the *INTERNAL MAMMARY*, the *UPPER*

DIAPHRAGMATIC, and others, which are dispersed in the breast: when the subclavian hath passed out of the thorax, it receives the name of the AXILLARY ARTERY; and when in the arm the HUMERAL, and in the fore arm the CUBITAL.

The upper portion of the aorta descendens sends off the BRONCHIALES, ŒSOPHAGEÆ, INTERCOSTALES, &c.

The inferior portion of the aorta sends off the inferior, DIAPHRAGMATIC, CŒLIAC, MESENTERIC, SPERMATIC, EMULGENTS, &c.; then dividing into two, forms the ILIAC ARTERY, which sends off branches about the lower part of the belly; then descending into the thighs, legs, and feet, form the CRURAL, TIBIAL, &c.

Wounds of the large blood vessels require amputation too frequently; the great quantity of blood which would be lost, if the usual methods to restrain hæmorrhages should fail, would endanger, if not destroy, the patient. After a ligature is formed, the circulation may be duly carried on by the anastomosing vessels; if it should not, the operation will be indispensable, to prevent mortification. The intercostal artery, when wounded, is fatal. Wounds of the arteries in the hands are dangerous. The POPLITEAL ARTERY in the ham, if injured, absolutely demands amputation, unless the operation recommended by Mr. Hunter, in case of the popliteal aneurism, should succeed. See ANEURISM. The HUMERAL ARTERY, if injured high up, requires the amputation of the arm. Bell's Surgery, i. 97, &c. White's Surgery, 173.

ARTE'RIA A'SPERA. See ASPERA ARTERIA.

ARTE'RIA VENO'SA. The pulmonary artery was so called by the ancients, from a mistaken notion that the veins came solely from the right, and the arteries from the left, ventricle.

ARTER'ICA, (from *arteria*, an artery). See AMUC'TICA.

ARTERIO'SUS, DU'CTUS, a passage conveying the blood from one artery to another; also called *canalis*, and *canaliculus arteriosus*. This, in the fœtus, arises from the extremity of the *arteria pulmonalis*, just where it is going to give off the two branches, and opens by its other end into the beginning of the descending aorta, just below the great curvature. In the adult it is obliterated; but in the fœtus it is open, and conveys the blood, which hath no passage, or a very slight one, through the lungs in this state, from the pulmonary artery to the aorta.

ARTERIO'TO'MIA, (from *αρτηρια*, an artery, and *τεμνω*, to cut). It is the opening of an artery for the discharge of blood.

Galen, Antyllus, Oribasius, P. Ægineta, and several others, highly extol this practice in inveterate headachs which resist all other means; and as a remedy against violent inflammations of the eyes, the epilepsy, &c. The operation is generally confined to the head, because of the bone being immediately under, and giving the advantage of a proper compress. When the temporal artery is opened, a small knife, such as is used for the fistula lachrymalis, is better than a lancet, and the incision must be so as to divide the artery transversely; then the inconvenience of an aneurism is avoided. Modern authors are greatly divided respecting the utility of arteriotomy. It certainly takes away a large proportion of the blood at once, but relieves only remotely the internal vessels; nor is it certain that its effects are in any instance more considerable than those of bleeding

from the arm, if the blood be taken from a large orifice. An inconvenience arises from the mode of the operation, as the artery is cut through, and, consequently, the other vessels are afterwards filled beyond their due proportion. Dr. Butter attempted to remove this inconvenience by opening the artery longitudinally, and contriving an instrument to prevent the troublesome suppurations which are often the consequence. Yet this instrument was only effectual by compressing and obliterating the artery, so that little was gained by the attempt.

Heister condemns arteriotomy, especially before every other method hath been tried. See Bell's Surgery, i. 146. White's Surgery, 173.

ARTETI'SCIUS, or ARTETI'SCOS. One who suffers the loss of any member, or who hath a very defective one.

-ARTHANI'TA, (from *απτος*, bread, because it is the food of swine,) the name of an ointment prepared from *cyclamen*; *panis porcinus*, called in Myrepsus, *casamum*, SOW BREAD. It is the *cyclamen Europaum* Lin. Sp. Pl. 207.

The root when fresh has an extremely acrimonious biting taste, which it loses almost entirely on being dried; it is recommended chiefly in cataplasms, for scirrhus and scrofulous tumours, and chilblains, though internally it proves cathartic and emmenagogue. It operates slowly, and with great virulence, inflaming the fauces and intestines: one drachm of the powder purges, and often destroys worms.

ARTHE'TICA, or ARTHRE'TICA, (from *αρθρον*, a joint). The herb GROUND PINE; useful in gout and all disorders of the joints. See CHAMÆPITYS.

ARTHOI'CUM, or ARTOI'CUM, or PANNO'NIUM, (from *αρτος*, bread). A red oil formerly made by digesting several roots with bread.

ARTHRE'MBOLUS, (from *αρθρον*, a joint, and *εμβολω*, to impel). An instrument for reducing luxated bones.

ARTHRI'TICA, belonging to the gout.

ARTHRITIS, the GOUT, (from *αρθρον*, a joint, because it is commonly confined to the joint).

Dr. Cullen, in his Nosology, gives it the name of *podagra*, (from *πους*, pes, the foot,) because he considers the foot as the seat of the idiopathic gout. The disease is placed in his twenty-fourth genus of diseases of the class of *febrile complaints*, in the order of *phlegmasiæ*, and he divides it into four species.

1. *PODAGRA REGULARIS*, REGULAR GOUT, when the inflammation appears in the joints to a due degree, and, after continuing a while, gradually disappears, and the patient recovers his usual, or a more improved health.

2. *PODAGRA ATONICA*, ATONIC GOUT, when there is manifestly the gouty diathesis; but from some cause it does not produce the inflammatory affections of the joints, but digestion is disturbed, and the general health variously affected.

3. *PODAGRA RETROGRADA*, RETROGRADE or RECEDENT GOUT, when inflammation hath as usual attacked the joints, but not either in its usual degree, or with the usual pain, and then suddenly abates, with an equally sudden affection of an internal part.

4. *PODAGRA ABERRANS*, MISPLACED GOUT, when the gouty diathesis produces inflammation in some internal part, instead of the joints of the extremities. It is generally and concisely defined 'an hereditary disease.

arising without any external evident cause, but preceded for the most part by an unusual affection of the stomach; febrile symptoms; pain in the joints, particularly of the great toe, but certainly in those of the feet and hands; returning at intervals, and often alternating with affections of the stomach, and internal parts.' The gout is called *nodosa*, knotted, when it forms small tumours at the joints.

The ancients called all kinds of pain, when seated in the joints or the external parts, by the common name of *arthritis*. The word rheumatism was not known amongst them; but, in the sixteenth and seventeenth centuries, some celebrated French physicians have called the pains which afflict the intermediate spaces between the joints and muscles of the neck, or of either arm, or of the anterior or posterior part of the thorax, the shoulders, scapulæ, thighs, and hands, by the name of rheumatism. Those they style arthritic which affect the joints: it was called *podagra* in the feet, *chiragra* in the hands, *onagra* and *pechyagra* in the elbow, *genagra* in the knee, *dentagra* in the teeth, *cleisagra* in the articulations of the clavicles with the sternum, *omagra* in the articulation of the humerus with the scapula, *rachisagra* in the spine of the back; if it seizes the larger tendons, *tenontagra*. Cœl. Aurelianus, lib. v. cap. 2. But the difference betwixt the gout and the rheumatism is considered as very great, both in their cause, seat, symptoms, and cure.

The gout is divided into REGULAR and IRREGULAR. The first chiefly affects the membranes and ligaments of the joints, particularly the small joints of the feet. The last afflicts the patient variously, and seizes the internal parts, chiefly the viscera, the lungs, and the head.

The first approaches of the gout are generally sudden, and happen very early in the spring or in the beginning of winter. The regular fit is usually preceded by indigestion, flatulency, drowsiness, headach and sickness; a weariness; dejection of spirits; pain and coldness in the limb, with a sensation as if wind or cold water were passing down the thigh; swelled veins, and frequent cramps. The appetite is sometimes very keen a little before the fit approaches, and the other symptoms sometimes disappear; a slight pain is however felt in passing the urine. Soon after midnight, or rather about two or three in the morning, a pain attacks the great toe, or some other part of the foot or ankle, though now and then it is fixed in the calf of the leg; this pain is accompanied with a sensation as if cold water was poured on the part, and soon followed by a shivering, with some degree of fever: after this the pain increases, and fixing in the small bones of the foot, the patient feels a torturing pain for about twelve or twenty-four hours, which then abates, the part becomes inflamed and swelled; towards the morning the patient falls asleep, a perspiration comes on, which terminates the fit. But what is commonly called a fit of the gout consists of several similar attacks; the pain frequently shifting from one foot to another, or from the feet to the hands; and though a recovery should follow the first remission, some uneasiness returns every night, and goes off the following morning. The first fit may continue two or three weeks; but a tenderness, where the pain was seated, remains much longer. The patient may remain free from any return during the succeeding, or a second

year; but the succeeding fits are then often still more painful; and soon after this the returns grow more and more frequent, increasing until the strength fails, and sensation is diminished. Though the patient is then seldom free, he is not violently afflicted. At this period chalky concretions occur, which, accumulating, destroy the motion of the joint: when large they burst through the skin, forming painful and troublesome ulcers. After this event the constitution has often remained free from gout many years; and we have often seen, about the period of seventy or seventy-five, a very violent and in a great measure an irregular fit of gout, which has left the patient for the remainder of his life free from any further attack, in tolerable health.

Much has been said by different authors concerning the cause of the gout. Boerhaave considers it to be a vitiated disposition of the very minute vessels and nerves in the body, from their too great straitness and rigidity; and, also, of the liquid which nourishes the nerves, from its acrimony, and greater tenacity. Hoffman says it is a saline tartarous substance, while some consider it a corrosive bilious salt, others as an acid, an earth, an alkali, or an austere styptic principle. In general, it is thought that the gout depends upon a certain morbid matter always present in the body; and that this matter, by certain causes, thrown upon the joints and other parts, produces the several phenomena of the disease. Dr. Kirkland thinks the *predisposing* cause a largeness of the lacteals and straitness of the small vessels, particularly those of perspiration; and the *immediate*, the acrimony of earthy particles undissolved.

That gout is caused by a morbid matter of some kind is a consequence apparently so clear and obvious, that it is not surprising to find it made the basis of every theory. Indeed, nothing but the strong mind and intuitive sagacity of Dr. Cullen, could have led us from this beaten track. It is indeed an argument against the existence of morbid matter, that authors have differed so widely respecting its nature; yet we have depositions of chalk stones in the joints, and the observation of Berthollet, that previous to the fit there is a less proportion of phosphoric acid in the urine. If however the chalk stones were the morbid matter, we should see the deposition most copious after a regular fit: they do not however appear until the constitution is weakened, and the fit irregular; and the retention of the phosphorated salt is not peculiar to gout, but generally attends irregular fevers, which chiefly affect the nerves, as we have often seen. Morbid or acrid matter in the blood will undoubtedly produce fever; but there is no instance where this effect follows, but from some previous change in the state of the constitution, as we shall in a future article show; and, in the instance of hectics only, does this morbid matter produce such regularly formed remittents. Indeed, whether in the access or the decline, the degree of the paroxysm of gout is determined soon after its attack; with the force of its invasion it continues for twelve or twenty-four hours. The kind of inflammation also is peculiar; and it is surprising, that though we have had so many medical arthritics, this has not yet been pointed out. The pain though violent, and the part though brightly ruddy, feels numbed, heavy, and incapable of action. If the pain could be for a moment forgot, the foot would be found to feel like a paralytic one; and, though the muscles

which raise the leg are not affected, they drag it along with great difficulty.

Again, supposing morbid matter a cause of gout, the most violent and regular fit should discharge it by depositions on the ligaments, by perspiration, or by urine; but every arthritic knows, that at the moment the most regular fit has ceased, it may be again produced by a variety of causes, and run the same course as before; nor after this second deposition are many constitutions secure. Besides, if there is a period of time when the arthritic is more than at any other free, it is the day or two before the attack. Where then is the matter?

The predisposing and the exciting causes are equally inconsistent with morbid matter. The former are causes of debility, and the latter cold irregularities of diet, particularly an indulgence in acescents, violent vexation, or fits of passion. In short, however probable the doctrine, however plausible the arguments, the system is untenable.

Dr. Cullen, in his *Pathology of the Gout*, says, in some persons there is a certain vigorous and plethoric state of the system, which, at a period of life, is liable to a loss of tone in the extremities. This is in some measure communicated to the whole system, but appears more especially in the functions of the stomach. When the loss of tone occurs, while the energy of the brain retains its vigour, the *vis medicatrix nature* is excited to restore the tone of the parts, and accomplishes it by exciting an inflammatory affection in some part of the extremities: when this has subsisted for some days, the tone of the extremities, and of the whole system, is restored, and the patient returns to his ordinary state of health; and it is owing to a deviation in some of these principles that he accounts for the difference in the species. Dr. Cullen, and indeed several others, consider the gouty matter as an effect, and not a cause, of the disease.

To this theory there may be numerous objections; yet the principle is clear, that gout is a disease of the constitution; that it is produced by debilitating causes; and that the inflammation excited in the ligaments, seems to restore the tone. In an impending fit of gout, an emetic, with aromatics and bark given freely, has suspended or prevented it. The kind of inflammation, and the means by which this change is effected, we cannot yet understand. The boasted *vires medicatrices nature* will, we suspect, be ultimately found only accumulated irritability in consequence of its suspension; and we must at last refer to a principle already stated, which we shall often recur to, that debility occasions irregular action only. Thus, in gout, while the extreme vessels are powerfully excited, the muscular system is apparently more torpid; and this torpor of the nerves and muscles of the extremities is, on the other hand, compensated by increased tone of the stomach. If it were the object of this work to build systems, this might be easily expanded: it is our wish rather to establish principles.

As the gout is allowed to be constitutional, so it is undoubtedly hereditary: and the predisposition is often from hence so strong, that avoiding most strictly the remote causes will not prevent it. We must, however, admit, that the disease is most often the effect of the accumulated consequences of the remote causes. These are excesses of every kind; long continued anxiety,

deep study, late hours, inactivity, &c.: each a cause of exhausted irritability.

The distinction of gout is a subject of considerable importance. Its relation to rheumatism often occasions much difficulty; and, though we consider the two diseases as perfectly distinct, yet they are sometimes so combined and blended, as to prevent our seeing which is the principal complaint. In general, rheumatism occurs in consequence of an evident cause, as cold; the gout without any such cause. Rheumatism has no preceding complaints; gout is preceded by languor, flatulency, and indigestion; rheumatism is the disease of the strong and active; gout of those advanced in life; rheumatism attacks the larger, gout the smaller joints; rheumatic limbs, though swollen, are not red like gouty; and rheumatism is not attended with fever so decidedly remitting. These circumstances will contribute to the distinction; but the cases so often run into each other, differ by shades so transient and minute, that the greatest difficulty is found in the distinction of particular complaints.

Another disease has occasioned us some little trouble, viz. a *gutta rosea*; an erysipelas affecting the joints, sometimes attended with pain. The distinction, though not easy, is on the whole sufficiently clear. The *gutta rosea*, though of a bright red, has not the peculiar colour, nor the shining appearance, of gouty inflammation: it does not exacerbate with the regular exacerbations of fever: it is not preceded by languor, which is removed by the pain; but often attended through its whole course with the particular low fever which attends erysipelas. The pain is rather in the *skin* than the *ligaments*, and the tumour bears pressure without greatly increasing it.

Some irregular pains in the joints have been styled gouty, but they are sometimes found in gouty habits without partaking in the nature of the disorder. The only requisite object of attention is, to be cautious in the use of cold applications.

The *prevention* of gout has employed the attention of the ablest physicians; and we shall first consider the mode of prevention in those who have a strong predisposition to the disease, as well as in those who have experienced one or two gouty paroxysms. We shall afterwards consider the means of relieving or preventing the fit in those who have for a longer time experienced the disease.

If a person is strongly predisposed to gout, abstinence and exercise are absolutely necessary. In the works of an old experienced physician, a mode of diet is directed, consisting of different vegetables in each month. In fact, a milk and vegetable diet is in a great degree necessary, and these directions imply no more. The exercise should be constant and steady, not to fatigue, but to keep all the secretions in their due course. Walking is the only proper exercise; and if to this be joined a dry free air, frequent washing the feet in cold water, and daily friction with a flannel and a flesh brush, we shall obtain all the necessary advantages. Where the predisposition is not so strong, the severity of these rules may be relaxed: a little animal food of a mild nature may be allowed once a day, and cyder may form a portion of the drink. Above all, however, temperance, cheerfulness, early hours, and moderate study, only are requisite: the mind must be occasionally employed as

well as the body, for idleness may lead to excess, to uneasiness, and its train of consequences.

If fits regular and painful have occurred, the general plan must be the same. Such, however, is the excruciating nature of this frequent disease, that men have gladly caught at every confident promise. On the first appearance of a fit an emetic has been recommended, to be followed by large doses of bark during the first remission. This it is said has succeeded, and it seems a probable measure, but we confess that we have had no experience of it. The Duke of Portland's powder has certainly prevented the return: it is said, however, by the first authorities, that the most fatal diseases, as apoplexy, dropsy, asthma, and infarcted viscera, have been the consequence. Indeed the circumstance of the remedy, though a very old one, having never maintained its credit for any long continued period, is a strong presumptive evidence of its injurious tendency.

Another remedy employed to prevent gout is a warm cordial ecceprotic. Boerhaave's gout cordial is the prototype of all the secret formulæ handed about with much mystery and confident pretensions. It consists of an ounce of rhubarb and two drachms of senna, with a drachm of cardamoms, and as much coriander seed digested in a pint of brandy. We omit the raisins, the saffron, and the cochineal, as useless additions. It has been our fortune to see this often tried with success, *it is said*: indeed the gout has been prevented, but in every instance apoplexy has terminated the scene at no very distant period. Alkaline aerated water and slight antimonials have been also recommended; but, as they have had no effect on the disease, they have done no injury to the constitutions. Costiveness should be undoubtedly avoided, and for this purpose the *pil. rufi*. with a few grains of the *pulvis antimonialis* given occasionally, or every other night, in constitutions liable to costiveness, has completely succeeded in our hands, and been equally effectual with the analeptic pills of Dr. James.

When the fits have appeared, other methods have been resorted to. Dr. Stevenson recommended blisters to the part, and spoke highly of their effects; but he, unfortunately, fell himself an early victim to the gout. Leeches have been recommended by others, it is said, with advantage. A new plan has been lately urged with some violence by Dr. Kinglake of Taunton, viz. immersing the affected part in cold water, and treating the disease as a common inflammation. It is not easy to speak, *flagrante bello*, without giving offence to one party, but we are impelled by considerations much more powerful than a desire of popular applause. We need therefore only observe, that the plan is wholly inconsistent with every thing we have seen or *felt* of the disease; and though we doubt not but constitutions have been found so robust as to prevent any injurious consequences from the trial, as some may lie in damp sheets, or take the Portland powder with impunity, yet to the generality it would, we fear, be fatal.

When the fit of gout is formed, it should perhaps be permitted, if regular, to pursue its course without interruption. It has been usual to lay it in soft flannel to 'keep it out' by a warm regimen, and keep the bowels open by the warmest tinctures: the true gout purgative, says an author of credit, is equal parts of the tinctura sacra and senna. The whole of this system we suspect to be erroneous. The pain of the fit is a remedy

produced by nature; and as we in no instance understand, and cannot in any imitate it, we think the whole process should be her own. We can throw out more gout by hot cordials, but we seem not to render the system freer; we can increase pain, but we do not by this means increase the tone of the stomach. It seems to us more rational, neither to clothe the part warmer nor colder than usual; not to change the diet or the drinks, unless languor or faintness makes cordials necessary. The burning heat of the part will prevent any bad effects from a common degree of cold, and we have generally found the swelling go on sufficiently and effectually without urging or repressing it. We now speak, however, of a regular inflammatory gout. Many discussions occur in authors respecting the propriety of giving opiates in gout; our decision must depend on their general effects. If they relieve pain, without producing languor, sickness, or faintness, in other situations, they are of service in gout; and, joined with antimonials or ipecacuanha, they have often, we think, shortened and mitigated the fit without apparent injury. It is recommended not to give them in the beginning of a fit; indeed at that time they are of the least service. We see no room for choice among the different preparations, though Dr. Warner prefers his own formula. A tincture of opium in Madeira wine we have some reason to think an useful form; and the Dover's powder, with the acetated ammonia, we have known highly serviceable. Gradually and gently moving the foot, as soon as motion can be borne without much pain, seems to prevent stiffness and weakness in the joint; and to wipe over the part with lukewarm water when the pain is abated, gradually substituting cold, contributes greatly to strengthen it, and remove stiffness and the more troublesome feelings. It often seems, however, to bring back a little soreness. Purging must be avoided at the end of a fit, as it often brings on a return: a circumstance not easily reconciled with the doctrine of morbid matter.

We have not mentioned some of the less common and less useful remedies. Bleeding has been recommended in strong and inflammatory habits; but it is, we believe, always injurious, even in misplaced gout. The moxa, the woolly part of the leaves of the Chinese artemisia, has been formed into a cone, the top of which is set on fire, and gradually consuming, an eschar is formed on the part, which in a few days suppurates. It is commonly used in the East, and said to lessen the pain without danger. It has been safely employed in this country; and, if we recollect rightly, Sir William Temple speaks of it in his own case with commendation: this method of relieving the fit is however disused, and we cannot recommend it from experience. Emollient poultices and warm bathing have been employed for similar purposes, but they are certainly injurious. We have often known a pediluvium too warm bring back a paroxysm, and even wiping the foot with a cloth wetted with water a little warm, has brought back some soreness. Camphor, dissolved in aromatic oils, has been applied to the pained part, but we cannot say with advantage. Any inconvenient symptoms which arise during the fit, should be opposed with the appropriate remedies. Sickness is removed by a gentle emetic; and the vomiting should be supported by mustard whey, the seeds of the cardus in infusion, or camomile tea with hartshorn. The bowels should be kept regular with a mild aloetic pill;

and a little anxiety, restlessness, or sighing, is relieved by camphor and æther, with sometimes a slight opiate. To regain the strength after a fit, bark has been recommended, but we are told that it should not be given till the urine has deposited the lateritious sediment. In the intervals of regular inflammatory gout it is unnecessary; cold bathing and Bath waters, though admissible, are equally so.

REPELLED OR MISPLACED GOUT is most nearly connected with the inflammatory, and we now speak of those internal inflammations decidedly from this disease, whose proper seat is the joints of the extremities. Gout is thus *misplaced* in consequence of debility of the constitution, or different causes which have contributed to repel it from the extremities; and the disease scarcely differs from similar inflammations of the same parts from other causes. We find a great difficulty in giving general directions on this subject, as it is so greatly varied by the degree of the complaint, and the different habits of patients; and might perhaps safely rest the whole on this general advice, that *such inflammations should be treated according to the usual plans, adverting however to the danger of producing atonic gout by excess of evacuations, particularly of purging.* The difficulty and danger, however, of these attacks render some further consideration necessary.

It has been the chief object of practitioners to bring back the gout to the extremities; and for this purpose they bathed the feet in warm water, wrapped them in the most stimulating cataplasms, and even applied blisters; wondering that they did not bring back gout by means, which, had it been in the extremities, would have driven it away. They have at the same time given the strongest cordials internally to excite the stomach, and thus produce the natural reaction; and have seen with admiration, that, while they have been intent on gout, their patient has died from inflammation. The most common species of misplaced gout are, gout in the *head, lungs, stomach, intestines, and kidneys, or bladder.* These we shall consider in their order.

GOUTY PHRENTIS differs in no respect from this disease, arising from other causes. Topical blistering is, if possible, still more necessary, and purgatives must be employed with caution and reserve. If any remedy is peculiarly applicable in this case it is the camphor, and a small proportion of nitre may be cautiously added. Towards the conclusion, when a wandering delirium alone remains, æther, with a slight opiate, is highly useful.

GOUTY PERIPNEUMONY in young strong habits sometimes requires bleeding; but it should be employed from necessity only, and the blood taken in no greater quantity than is necessary to remove the most urgent symptoms. Blisters, as usual, are peculiarly advantageous; with antimonials, guarded in their purgative powers by opium. In this case, too, camphor has been of the greatest service; and the squills, with the gum ammoniac, may be given freely as in the more common cases. A bastard peripneumony is very often gouty: the spitting is copious, but the complaint is not relieved by it, and the whole tribe of expectorants appears to be useless. In this case a brisk warm purgative will occasionally bring on gout in the extremities, though it will more often fail, and in such instances we have found the bark with aromatics the best remedy. The balsam peruvia-

num in large doses promises to be successful, but we have not had sufficient experience of it, as the bark has so generally succeeded. The lac ammoniac, also, with a large dose of salt of hartshorn, or perhaps the sal succini, might be useful.

GOUTY GASTRITIS is sometimes peculiarly painful and troublesome, but fortunately very uncommon; and yields easily to a blister, with slight opiates, and warm, mild, diluting liquors. The necessary stools must be procured by clysters.

GOUTY ENTERITIS requires minute attention, for purging is its only remedy. It might appear probable, that, as purging contributes to bring on regular fits, its effects might be salutary in this way. It must, however, be recollected, that active purging, if it fails in this respect, brings on atonic gout; and this coincidence would render the disease more unmanageable. Motions must, however, be procured; and it fortunately happens that after the application of a blister, this is no very difficult task.

GOUTY NEPHRITIS is very uncommon. Dr. Cullen seems unwilling to admit this inflammation as in any case arising from gout. The question is of very little importance, since, if we avoid the more active antiphlogistic remedies, the cure of this disease is by no means peculiar. In the *bladder*, gout sometimes produces very peculiar effects: an inflammation from this cause occasions violent pain, an obstinate strangury, and with the urine discharged there is a considerable quantity of a light mucus, resembling purulent matter. It is a species of a disease which we shall afterwards notice under the appellation of a catarrhus vesicæ. In this case warm diluting liquors, with the most stimulating applications to the perinæum, are absolutely necessary; and we have even been obliged to apply a blister to this part, carefully removing it early to prevent absorption. The complaint, however, is not obstinate.

ATONIC GOUT is a disease peculiarly obstinate and distressing: it is the prelude of misplaced gout, and appears often in the interval between the repulsion of the active inflammation in the feet, and the attack on the viscera. It is known by the various forms of debility and irregular action in gouty habits. Low spirits, giddiness, headach, fainting, melancholy, wandering delirium, palsy, and apoplexy, are occasioned by its affecting the head; bastard peripneumony, asthma, and, it is said, consumption, when it attacks the lungs; anorexia, dyspepsia, eructations, and hiccough, when in the stomach; diarrhœa, dysentery, irregular pains, and obstinate costiveness, when in the bowels; in the bladder, stone; in the intestinum rectum, piles, terminating often in fistula. In all these complaints we are directed to bring on gout. We may indeed 'call spirits from the vasty deep,' but they will not obey. The direction is easily given, but it cannot be executed. In such cases we may remove the present complaints, strengthen the constitution, lay the foundation for future gout, but we can do no more. Bark and aromatic cordials are in such cases proper; the bowels must be kept free by aloetic pills, occasionally interposing the warmer tinctures, encouraging exercise and cheerfulness, keeping the stomach in a proper state by occasional emetics and a moderately warm generous diet, changing the scene, and diversifying the objects. These are the cases chiefly benefited by mineral waters, where all these means are

combined, and those of Bath are unrivalled for their powers in this state of the disease. In many such instances sea bathing may be allowed, especially when young people, either from the violence of the hereditary disposition to gout, or their own early imprudence, have become premature martyrs to the disease. In cases where stone is combined, the Pyrmont waters, which contain the fixed air with steel, are highly useful; and the aerated alkaline waters are often found serviceable. If the Cheltenham waters do not prove too purgative, they may be also useful. Steel itself is often employed, and probably with advantage: there is little choice in its preparations; but if the stomach is much disordered with flatulence, the flores martiales with the gum pill will probably be most useful, washed down with a warm cordial.

In all violent attacks of the head and stomach, the warmest cordials must be immediately employed, and the Irish usquebaugh, as peculiarly warm and active, has been a favourite. If there is time for choice and preparation, the æther is preferable, or the union of the volatile alkali with aromatics in the spiritus ammoniæ compositus; and the efficacy of these remedies is increased by the addition of a warm opiate. The doses must be measured only by the exigency; and the quantity of spirit sometimes swallowed in such instances, not only with impunity but advantage, is astonishing.

In the other complaints from gouty atony, a more regular and steady stimulus is required. To the common cordials, Cayenne pepper in pills has been added; and the arum, in large doses, has been often useful. The serpentaria, particularly its tincture, we have often seen employed by former practitioners with advantage, and have perhaps from that cause contracted a predilection for it. No medicine, as a permanent and powerful stimulus, seems to exceed it in these cases. When fistula, stone, or other diseases, come on, which require peculiar treatment, the relief must be conducted in the usual way.

RETROCEDENT GOUT is in reality the atonic, but it is generally distinguished by authors; and we notice it just to mention, that on the sudden recession of gout a variety of nervous medicines, as æther, musk, and castor, have been employed. Except as stimulants, they seem to possess no peculiar advantage; and perhaps, as superseding the full use of stimulating medicines, they may be injurious.

The warm bath has been employed at the end of a fit, to restore flexibility to the joints; and the warm waters of Bath are, on many accounts, preferable. A muriatic bath has been lately advised; that is, water slightly impregnated with the muriatic acid; and, like all novelties, highly commended. When we speak of warm bathing, we shall show that the water does not penetrate beyond the cuticle, and of course that the acid cannot reach the calcareous depositions; but it will be obvious to any one who observes the skin of gouty patients, that the same calcareous phosphat penetrates every part of the cuticle, and fills its rugæ. The muriatic acid will dissolve the salt; and this effect, with the influence of the heat and moisture, will restore in a great degree the pliability of the joint, and add to the comfort of the arthritic. Cold bathing also in the intervals of gout, when the system is wholly free, is an

excellent remedy for supporting the activity and energy of the constitution.

There are various other complaints that alternate with gout, viz. wandering pains, erysipelas, inflammations of the eye, pains of the back, resembling nephritic pains. These must be treated in the usual way, taking care, when the cause is suspected, not to lower the patient by too great evacuation.

This disease generally attacks men of robust and large bodies, men of large heads, plethoric habits, and whose skins are covered with a thicker rete mucosum, which gives a coarser surface; particularly if the earlier period of their life has been spent in indolence and luxury, or if their minds have been much harassed with vexation and painful reflection. It seldom attacks persons employed in constant bodily labour, or those who live much upon vegetable aliment; and it is less frequent among people who make no use of wine, or other fermented liquors. It seldom seizes men before the age of thirty-five; oftener at a later period. Neither children nor youths are exempt from it; and the females who are liable to it are those of the more robust and full habits; though it seldom attacks that sex, or eunuchs, unless they are strong, lead indolent lives, and live very full.

See Sydenham's Works, who admirably describes the regular gout, with notes by Dr. Wallis: Musgrave on the Gout; he excels in his description of the irregular gout. See Warner's full and plain Account of the Gout; he includes the chief of what his predecessors have written on this subject. Cullen's First Lines, vol. ii. edit. 4. Kirkland's Inquiry, vol. i. Dr. Cadogan's Dissertation on the Gout. Hoffman De Dolore Podagrico. Boerhaave De Podagrâ. Dr. Kirkland and Cheyne on the Gout.

ARTHROCA'CE, (from αρθρον, a joint, and κακον, malum). An ulcer of the cavity of the bone, generally near the extremity, with caries. See SPINA VENTOSA. When in children it is styled hædarthrocace.

ARTHRO'DIA, (from αρθρον, a joint, and δεχομαι, to receive; or from αρθρωω, articulum fingo, to articulate). See DIARTHROSIS.

ARTHRODY'NIA, (from αρθρον, a joint, and οδυνη, pain). See RHEUMATISMUS.

A'RTHRON, (from αρω, to fit together). A JOINT. See ARTICULUS.

ARTHROPYO'SIS, (from αρθρον, articulus, and πον, pus). This word is variously used. Dr. Aitkin, in his Elements of Surgery, calls inflammation of a joint *phlegmone articuli*. By this name, in another part of the same work, he means an abscess in a joint; and, in a third place, uses it as synonymous with inflammation in the loins, particularly in the cellular membrane lying under the psoas muscle.

In Dr. Cullen's System it is a genus of *pyrexia*, of the order *phlegmasia*; and its synonyms are the *lumbago psoadica*, *lumbago apostematosa*, *lumbago ab arthrocace*, *ischias ex abscessu*, and *morbis coxarius*. In this disease, he says, there are pains in the joint or the muscular parts, which happen often after bruises; they are deep, dull, of long continuance; the swelling is either slight, or but little diffused; no inflammation; the fever at first is gentle, but at last hectic; and the part at length suppurates. See ABSCESSUS DORSI

et LUMBORUM, and ISCHIATICUS, under ABSCESSES; also PSOAS. Bell's Surgery, vol. v. 419. Kirkland's Med. Surgery, vol. i. p. 427.

ARTHRO'SIS, (from *αρθρω*, *articulo*). See ARTICULATIO.

A'RTIA. According to some it is the same as *arteria*; to others, as the *aspera arteria*.

ARTICO'CA, or ARTICOCALUS, (from *αρτιος*, *perfect*, and *κωνος*, *the cone of the pine tree*). ARTICHOKE. So called from its likeness. See CINARA.

ARTICULARIS MORBUS, (from *articulus*, *a joint*). When the ancles and knees swell and inflame from gout, it is thus named.

ARTICULARIS VENA. Called also *sub-humeralis*. Under the head of the os humeri, the basilica vena sends off this branch. It passes almost transversely round the neck of that bone from within backwards, and from behind outwards, and runs upon the scapula, where it communicates with the *venæ scapulares externæ*.

ARTICULATIO, (from *articulus*, *a joint*). ARTICULATION; *arthrosis*; *coarticulatio*; *apharthrosis*; *pro-sarthrosis*; *assarthrosis*; *campe*; *junctura*; *commissura*; is the joining of bones together, and is of two kinds, viz. *articulation* and *connection*. *Articulation* is of two kinds; 1st, DIARTHRO'SIS. 2dly, SYNARTHRO'SIS. There is a species composed of these two, which some call AMPHIARTHRO'SIS. See each under their separate terms. CONNECTION is of three kinds. See SYMPHYSIS.

ARTICULUS, (a dim. of *artus*). A JOINT; also *arthron*. The diseases of the joints are, LUXATIO, SUB-LUXATIO, and ANCHYLOSIS, which see. The insertion of a number of tendons into the ligament serves not only to strengthen it, but, by their action, to hinder it from being pinched in the motion of the limb, which is a mechanism observed in every joint of the body. Wounds in the joint often require amputation. See VULNUS.

ARTICULUS MORTIS. The last pang of expiring life. At this period many changes occur, which have been attributed to previous disease: polypi are formed in the heart and larger vessels; extravasation in different cavities sometimes takes place; the veins are emptied, and the larger vessels unusually filled.

ARTIFICIA'LE, (from *ars*, *art*, and *facio*, *to make*). Whatever is made or prepared either of the native cinnamon itself, or from the vein of cinnamon; or any thing made or substituted by art.

ARTIFICIALIS SAL. See MARINUS SAL.

ARTISCO'CUS LÆVIS. See CINARA.

ARTISCUS, (from *αρτος*, *bread*). Troches are thus called that are formed like a loaf. An ingredient in the famed theriaca was distinguished by this name, as it consisted of viper's flesh made into a troche by means of bread. Viper's powder was afterwards substituted.

ARTIYO'CHROS COLOR, (from *αρι-υπο*, and *ωχρος*, *pale*). A palish yellow colour which attends a disorder of the spleen, or chlorosis.

ARTIZO'A, (from *αρι*, and *ζωη*, *life*). SHORT-LIVED.

ARTOCARPUS, the BREAD-FRUIT TREE. *A. incisa* Lin. filii supplem. p. 61. Nat. order *urticeæ*. The leaves exude a milky juice when broken: the fruit about the

size of a child's head, and the skin reticulated. The eatable part between the skin and the core is white, farinaceous, and not unlike new bread. The taste is insipid, with a slight sweetness. See ALIMENT.

ARTOCARPUS, *integrifolia*, *sittitodium macrocarpum*. Thunberg's Philosophical Transactions, lxix. This is a native of Malabar, but inferior to the former, as more difficult of digestion. It contains a great number of nuts much larger than almonds, which are roasted like chestnuts, and in some measure resemble them.

ARTOME'LI, (from *αρτος*, *bread*, and *μελι*, *honey*). A sort of cataplasm prepared of bread and honey.

ARTOPTI'CIUS PANIS, (from *αρτος*, *bread*, and *οπιζω*, *to toast*). TOASTED BREAD.

A'RTOS, (from *αρτος*, *bread*). See PANIS.

A'RTUS, (from *αρθρον*; perhaps from *arto*, for *arcto*, because the limbs are joined one to another). A LIMB, A JOINT.

A'RTYMA, (from *αρτυω*, *to prepare*). See CONDIMENTUM.

A'RUBUS ARVINA, BUTTER. See ADEPS.

A'RUM. It is derived from the Arabic term JARON, *a dart*, which it exactly represents. Called also *arum maculatum*, *aron*, *jarus*, *isaros*, *fes vituli*, *barba aronis*, *serpentaria min.* *dracontia minor*, *alimum*. LORDS and LADIES, CUCKOO PINT, WAKE ROBIN. *Arum maculatum* Lin. Sp. Pl. 1370. Nat. order *pipерите*.

The root is irregularly round, tuberous, about an inch thick, sending off many long simple fibres; and in the medicinal part of this plant it is brown on the outside, and white within. It is acrid and pungent to the taste; the sensation continuing for some hours, but it may soon be relieved with a little milk. The firm, hard roots should be chosen. They lose their acrimony by drying, and by heat they become a bland farinaceous aliment; but a syrup made with them would probably keep as well as the syrup made of garlic. They afford nothing by distillation nor infusion; yet if buried in fresh sand, and kept just moist only, their virtue is preserved unimpaired. Bergius considers this root as stimulant, aperient, and diuretic; and indeed the more ancient writers speak highly of it, both as an internal and external remedy. Bergius considers it as useful in a pituitous colluvies, loss of appetite, sympathetic headach, humoral asthma, and intermittent fever. Arum is certainly a very powerful and permanent stimulus; and by promoting the secretions may be advantageously employed in cachectic, chlorotic, paralytic, and rheumatic affections, and in various other complaints of phlegmatic and torpid constitutions; but more especially in a weakened relaxed state of the stomach. That it contributes to dissolve the viscid mucus, we have no reason to think, though, as an active stimulant, it may prevent its accumulation. Its greatest utility seems to be in palsies, in chronic rheumatisms, and in atonic gout, where a permanent stimulus is wanted. In such cases, it has proved a remedy of particular value. The conserve of arum, however, with three parts of sugar to one of the root, is too much inviscated. We have found equal parts almond rubbed down with each five grains has been sufficient. The dose is from ten grains to a scruple.

A'RUM MOSCHA'TUM. See PIPER.

A'RUM POLYPHY'LLUM, DRACU'NCULUS. See DRACONTIUM.

ARU'NDO, (from *aresco*, to grow dry). The reed.

ARU'NDO FA'RCTA I'NDIÆ ORIENTA'LIS. The DRAGON'S BLOOD CANE. It grows in the East Indies. The juice of its fruit is called dragon's blood, in drops.

ARU'NDO I'NDICA. See SAGITTARIA ALEXIPHARMICA.

ARU'NDO MAJOR and MINOR. Names of the tibia and fibula.

ARU'NDO SACCHARI'FERA, and VIVA BRASILIENSIBUS. See SACCHARUM.

ARU'NDO SYRI'ACA. See CALAMUS AROMATICUS.

ARU'NDO PHRAGMITES, Lin. Sp. Pl. 120, has been recommended as an antisyphilitic.

ARU'NDO BAMBOS. LOUREIRO. COCHINCHINENS. 56. This reed is used for many medicinal purposes, though of little importance. The flint found in its cavities, styled tabashir, is a singular curiosity, to which we may have occasion, for purposes more strictly medicinal, to allude.

ARVI'SIUM, so called from Arvisia, the promontory of the isle of Chios, where it was made. See MALVASIA.

ARYTÆ'NO-EPIGLO'TTICI. These are small fleshy fasciculi, each of which is fixed by one end in the head of one of the arytænoid cartilages, and the other in the nearest edge of the epiglottis.

ARYTENOIDE'Æ CARTILAGINES. See ASPERA ARTERIA.

ARYTENOIDES, vel ARETENOIDES, (from *αρταινα*, a funnel, and *ειδος*, shape). Hence from the shape it takes the name. The *arytænoid*, or EWER-LIKE CARTILAGE; called also *guttalis*, and *gutturiformis*. An epithet of two cartilages, which, together with others, constitute the head of the larynx.

ARYTENOIDEI MUSCUL. MINOR, vel OBLIQUUS, vel TRANSVERSA'LIS. They are situated on the back part of the arytænoid cartilage. They are very small muscles which run upon the surface of the greater arytænoid muscles: they arise from that part of each of the cartilages arytænoides, next the cricoides on the other sides, and terminating in that part of the other or adjoining the arytænoid cartilage that is furthest from the cricoides on the other sides. Their use is to assist the arytænoides majores in their action, which is much strengthened by the manifest decussation of their fibres. Douglas.

ARYTENOIDEI MAJO'RES. They are under the arytænoides minores. They have an insertion into the annular cartilage, and help to close the glottis. They arise fleshy from the arytænoid cartilages near their junction with the cricoid cartilages, and running transversely of an equal breadth, with straight fibres, they are inserted into the same side of the other cartilage. Their use is to shut the rimula, or chink called glottis, by bringing these two cartilages nearer one another.

ARYTHMUS, ENRYTHMUS, (from *α*, neg. and *ρυθμος*, a modulation, or modification of time and sound in music, but used to express order and harmony in general). Galen applies it to the pulse not modulating according to nature.

Every age hath its natural pulse, which, as long as it keeps in its due RYTHMUS, or modulation of time and force, is called EU'RYTHMUS; but if it deviates,

VOL. I.

it is a pulsus arhythmus. If it runs into a modulation proper to the next age, it is pulsus PARARYTHMUS. If it changes to a pulse proper for any other age, it is called pulsus HETERO-RYTHMUS. If it passes into a modulation not proper to any age, it is then a pulsus ECERYTHMUS, disorderly or irregular.

AS, was a weight and a measure amongst the Romans, each of twelve ounces. See CYATHUS.

A'SA, (from the Hebrew word *asa*, to heal, or perhaps *lasar*, the old name of *asafetida*).

A'SADU'LCIS, A'SADU'LCIS ODORA'TA. See BENZOINUM.

A'SAFCE'TIDA, vel A'SSAFCE'TIDA. *Andsjudan*. The STINKING HEALER. Also called *hingisch*, *laser*, *laser-pitium*, *silphium*, *hing*, *cyrenaicus succus*, *hindisch*, DEVIL'S DUNG. It is the fetid concrete juice of a plant which grows in Persia, and other parts of the eastern countries. Kempfer says, that the plant resembles lovage, and that it is the root which yields the gummy juice. See Kempfer's *Amœnitates Exoticæ*. It is the juice of the *ferula asafetida* Lin. Sp. Plant. 356. Willdenow 539, Sp. 11. Nat. order *umbellatæ*. Philosophical Transactions, vol. lxxv. The plant, however, greatly differs from that described by Kempfer. This juice is whitish at first, but it gradually becomes browner and harder. The best pieces that are brought into Europe are of a pale and yellow red colour, variegated with white masses or tears. This gum hath a strong fetid smell, like that of garlic, and a nauseous bitter biting taste, which it loses by keeping. Its smell and taste reside in the resinous part, which is  $\frac{1}{3}$  of the whole; spirit is therefore its best menstruum, though water extracts the greatest part of it by the aid of the gummy matter, consisting of  $\frac{2}{3}$ . In distillation with water the impregnation is strong, and a pale coloured essential oil is received; the remaining decoction affords a bitter extract. In the East, as by the ancients, it was used as a condiment, and has been thought an aphrodisiac.

As a medicine it is the strongest of all the deobstruent, fetid, warm gums; some suppose it more diaphoretic and expectorant than the gum ammoniacum, and more useful as a carminative and an emmenagogue than any other of the fetid gums. When it disagrees, the milder gums of similar efficacy should be used in its stead. The next to it is the gum galbanum; which, if too strong, must give way to the gum sagapenum, or to the still milder gum ammoniacum, or to myrrh, or to the wild valerian root, which is still milder. In flatulencies, and all the symptoms called nervous, it acts as an anodyne and antispasmodic; though sometimes the addition of opium greatly improves its efficacy. It is by far more quick in its effects than any other of the fetid gums; and it is the speediest in relieving the anxieties and oppressions of the precordia, which frequently attend nervous disorders, and nervous fevers: but in such cases its efficacy is also increased by joining it with opium, and sometimes, if not too nauseous, with valerian: one part of the first to two parts of the last may be a general proportion. Large doses of asafetida, with a blister on the back, have relieved in epilepsies, and in palsies that succeed epilepsies. In the nervous asthma, joined with an equal quantity of the gum ammoniacum, it greatly relieves; but it sometimes fails, and then the bark is to be tried.

C c

In hysteric complaints, fetids are only palliatives; in hysteric suffocations, a plaster of asafœtida ʒ vi. and camphor ʒ ss. mixed, by far excels those made of the gum galbanum; for camphor softens all the resins, and renders them more soluble. In whooping-cough it has been highly commended; and may probably be very useful, for its expectorant powers are considerable, and it is an excellent antispasmodic. In croup it has been also employed. When it cannot be given by the mouth, it may be safely and advantageously administered in clysters, from a scruple to the youngest children, to three drachms to adults, in from two to four ounces of water, and in this state it is an effectual destroyer of ascarides. We cannot find that it has been in any other respect useful as an anthelmintic. Externally it has been reckoned an useful application in bubo and paronychia. In nervous cases it acts as an anodyne sometimes where opium fails, and without leaving any lowness on the spirits: and where neither succeeds separately, they often answer if joined. Cullen's Mat. Med. The dose of the powder is from ten to thirty grains.

The officinal preparations are, the pil. ð gummi, consisting of two parts of galbanum, opoponax, myrrh, and sagapenum (each), and one part of asafœtida. We have found however the asafœtida, with soap and a small portion of aloes, a better form. Dissolved in spirits, it is more useful and quick in its operations. Of the fixed alkaline salt, a pound and a half is employed in disengaging the alkali of a pound of sal ammoniac, and this mixture is distilled with four ounces of asafœtida from three quarts of proof spirits. This is the volatile, fetid spirit of the dispensatories. The tincture consists of four ounces of the gum to a quart of spirit of wine.

A'SAB. See BOROZAIL.

A'SABA HERMES, (an Arabic term). It receives its name from Hermes, its inventor. But azaba meaning tinctured with yellow, as well as a finger, it may have been named from its colour. See HERMODACTYLUS.

A'SABON, (*asaphon*, Arab). See SAPO.

A'SAGAR. See ERUGO ÆRIS.

A'SAGEN. See SANGUIS DRACONIS.

A'SAGI AND A'SAMAZ. See VITRIOLUM.

A'SAMAR. See ERUGO ÆRIS.

A'SONON. PREPARED SAL AMMONIAC. See ALKALI.

ASA'PHATUM, (from α, neg. and σαφης, *clear*), minute eruptions, hardly visible. A species of serpigo, or impetigo, seemingly generated in the pores like worms. When the skin is pressed, they come out like long threads, with black heads. It consists in a retention of the sebaceous substance, and forms threads by hardening in the ducts.

ASA'PHEIS, (from the same). Patients who do not utter their words distinctly.

A'SAPHIA, ASAPHO'DES. It is the *paraphonia palatina* of Cullen. See PARAPHONIA. (It is derived from the same roots). Hippocrates uses this word to express a muffled hesitating tongue that hath no plain utterance; such a confused voice as proceeds from an interposition of the organs of speech. Sometimes this word signifies a dubious kind of delirium not easy to be discovered.

ASARABA'CCA. See ASARUM.

ASA'RCON, (from α, non. and σαρξ, *caro*). VOID of FLESH.

A'SARI PU'LVIS COMP. See ASARUM.

ASARI'TES. The wine of asarum, made with must, or sweet strong wine, ℥ vi. and asarum three ounces.

A'SARON, A'SARUM, (from α, non. and σαρπ, *to adorn*). So called because it was not admitted into the ancient coronal wreath: called also *nardus rustica*, *nardus montana*, WILD NARD, and COMMON ASSARABACCA. The species in use is the *asarum Europæum* Lin. Sp. Pl. 633. Nat. order *sarmentaceæ*: *aristolochiæ* of Jussieu. It is a native of the southern parts of Europe and the warmer climes, and raised in our gardens. The dried roots are brought from the Levant, but those of our own growth are nearly as good.

The roots and leaves have a somewhat strong but not unpleasant smell, somewhat like that of nard; and a nauseous, bitter, acrid taste, like arum. They have the same effect as a medicine; but when dry, three times the quantity should be given that is required of the fresh root: from thirty to sixty grains prove emetic and cathartic. In small doses this herb promotes the menses, is diuretic, and sudorific. Spirit of wine extracts all its virtues, and water a considerable portion of them. Boiled in water its virtues are destroyed, but it is still said to be a deobstruent.

Its operation is harsh, and its use in practice confined to that of an errhine; amongst which class it is found the most useful and convenient. A grain or two of the powdered root snuffed up the nose, procures a considerable evacuation for a long time, without causing the patient to sneeze; and, on this account, it has been found useful in diseases of the head, particularly in the more languid and phlegmatic constitutions. The leaves, though as strong as the roots in all other respects, as an errhine, are milder. The herb snuffs have this plant for their basis. Cullen's Mat. Med.

An ounce of juice expressed from the fresh leaves operates as an emetic in maniacs, when antimonials fail; and it is said to be useful in dropsy and intermittents.

The London college directs the following as a sternutatory: PULVIS ASARI COMPOSITUS. COMPOUND POWDER OF ASSARABACCA. It consists of equal parts of the dried leaves of assarabacca, marjoram, Syrian mastich, thyme, and dried lavender flowers.

This powder was called pulv. cephalicus.

A'SARUM VIRGINICUM, called also *serpentaria nigra*. BLACK SNAKE WEED.

This hath leaves like those of *pistolochia*, and are spotted like *arthanita* or sow bread. The roots are brought from Virginia, mixed with the radix serpentum Virginian, and are used as being the same.

ASA'SI, a tree which grows on the coast of Guinea, the infusion of whose leaves cures the tooth-ach. Phil. Transactions, N° 232.

ASBE'STINUM. ASBE'STOS, or ASBE'STUS. When the term is applied to the amianthus or earth-flax, it is derived from α, non. and σβεννυμι, *to extinguish*, because it is uninjured by fire; when to calx viva, or quick lime, it is on account of its unquenchable properties. See AMIANTHUS. Also a name for *calx viva*.

ASCALO'NIA. So called from Ascalon, a city of Judæa, where they abound. A species of ONIONS.

ASCALONITI'DES. ESCHALOTS, BARREN ONIONS, OR SCALLIONS.

ASCARDAMY'CTES, (from  $\alpha$ , non, and  $\sigma\kappa\alpha\rho\delta\alpha\mu\iota\tau\omega$ , to wink). One who keeps his eyes long fixed and immoveable without twinkling.

ASCA'RIDES, (from  $\alpha\sigma\kappa\epsilon\omega$ , to move about). So called from their continual troublesome motion. See VERMES.

ASCE'NSUS MORBI, (from *ascenso*, to increase). The ascent or increase of a disease.

A'SCETÆ, (from  $\alpha\sigma\kappa\epsilon\omega$ , to move about). WRESTLERS.

A'SCIA. See DELIGATIO.

ASCI'TES, (from  $\alpha\sigma\kappa\iota\varsigma$ , uter, a water bottle). So called from the protuberance of the belly resembling that of a bottle. It is the DROPSY of the BELLY; termed also *hydrocele peritonæi*. When water is accumulated in the cavity of the belly betwixt the peritonæum and the viscera, or rather in the duplicature of the peritonæum, it constitutes this disease. See Kirkland's Med. Surgery for an instance of an encysted ascites, vol. ii. p. 105.

Dr. Cullen ranks this genus of disease in the class *cachexiæ*, and order *intumescentiæ*; and he defines it a tensive, slightly elastic, but fluctuating, intumescence of the abdomen, of which he enumerates two species.

1st, ASCITES ABDOMINALIS, *abdominal ascites*: when there are a regular and equal intumescence of the abdomen, and a perceptible fluctuation; the varieties of which arise either FROM OBSTRUCTION OF THE VISCERA, FROM DEBILITY, OR THINNESS OF THE BLOOD; or from the nature of the liquid effused, whether *pus*, *urine*, *chyle*, or *oily fluid*.

2d, ASCITES SACCATUS, ENCYSTED ASCITES; when the ovaries, &c. are the seat of the disease, wherein the tumour of the abdomen, at least in the beginning, is partial, and the fluctuation less evident than in the former species.

Sauvages forms a different division, and by no means an useless one; he arranges the ascites into—1st, *The serous abdominal*, of which he forms thirteen varieties; 2d, *Serous not abdominal*, of which are six varieties; 3d, *Abdominal not serous*, of which there are five; 4th, *Neither serous nor abdominal*, of which he forms six varieties. See Nosologia Methodica, vol. ii. p. 498.

We, however, in this place consider such species only where a preternatural accumulation of water is the cause, from which no age or sex is exempt, though it generally occurs in old men, and women after child bearing.

The causes are various; viz. jaundice, great evacuations of blood or serum, long continued intermittents, asthma, a rupture of some lymphatic vessel, obstructions in any of the viscera, most frequently a scirrhus liver, repelled eruptions, atonic gout, polypi of the heart, steatoma of the omentum, or any thing that obstructs the return of the venous blood, large quantities of diluting liquors, or, in general, whatever can lessen the quantity of crassamentum in the blood, and weaken the system. But the immediate causes are either a rupture of the lymphatics, in which case the fluid ap-

pears whitish when tapping is performed, increased exhalation, or diminished absorption.

This kind of *dropsy* is sometimes very rapid in its approach and advances, then continues many years without making any progress; at others its advances are very slow, and a number of years elapse before it manifests itself in a confirmed state. One of the first signs is a languor and an aversion to motion, with pitting of the ankles towards the evening, and a shortness of breath; though it should be observed that the pitting of the ankles is not conclusive, since it often attends pregnant women, as well as old men with gross habits, when suddenly freed from an asthma under which they have laboured many years. If, after the swelling of the feet, the legs and thighs swell also, the case is plain, and these anasarca swellings usually precede *ascites*. The palms of the hands are dry and hard; perspiration is greatly diminished; the urine is less and less in quantity, appears turbid, high coloured, and deposits a large quantity of a lateritious sediment; the belly gradually swells; and, in proportion, the breathing becomes short, the appetite for solid food fails, and thirst increases; a slow fever sometimes attends; the face and arms are emaciated; a paleness at first, and afterwards a yellowish colour, is seen in the skin. These symptoms grow worse, and a dry cough comes on; the belly is greatly distended; and, *except the water is contained in cysts, or hath rendered the integuments too tense*, it may be felt to fluctuate by gently tapping one side of the belly with one hand, while the other is placed on the opposite side. At length little watery vesicles arise on the feet, which burst, and from them a quantity of water is discharged, which greatly relieves for a time, and has been known to remove the complaint. A mortification, however, frequently comes on; or, the strength gradually failing, the patient sinks from weakness, or is suffocated from accumulation of water.

If a scirrhus in any of the viscera is the cause, a cure is scarcely to be expected; since the swelling presses on the lymphatics and retards absorption. If an *ascites* succeeds other diseases, in which the viscera were injured, if the thirst is great, and other symptoms violent, there are but little hopes of recovery. An hæmorrhage, or an erysipelas coming on, with an increase of the fever, is highly dangerous. It is a bad sign when diuretics in every form, and of every different kind, fail. If the fluctuation, when the hand is laid on one side of the belly and struck with the other on the opposite side, can be felt only partially, tapping will afford a temporary relief; though, in such a case, we cannot expect to empty the belly totally; for this can only be the case when the fluctuation is felt by very distinctly striking on any point of the belly. But, on the other hand, if perspiration increases, or the discharge of urine becomes plentiful, these afford favourable prognostics. Indeed, without the urine continues to flow with tolerable freedom, or is compensated by other watery evacuations, there remains very little hope of a perfect recovery.

The distinction of ascites is of great importance, especially the distinction between the disease and the pregnant state. In an unmarried person, there is no disease which will so effectually conceal the real situa-

tion as dropsy; and, in a married woman, where there is no pretence or wish for concealment, dropsy will sometimes be considered as the cause, while the swelling arises from pregnancy, or is combined with it. Dreadful to relate! the trocar has, more than once, within our own observation, happily not by our direction, been plunged into a pregnant uterus.

When the unmarried libertine disguises her fault under the pretence of dropsy, we cannot expect to gain any information from enquiry into the state of the menses; for she can invent circumstances, as well as the principal fact. We must draw our conclusion, therefore, from the first appearance, the progress, and the state of the tumour. If a person of a phlegmatic, cachectic habit, finds a tumour gradually coming on, without beginning at the bottom of the abdomen, and a fluctuation is observable in this tumour; if, at the same time, the urine is scanty and the legs swell; we may conclude it to be dropsy. If, on the contrary, the tumour began to rise above the symphysis of the pubes; if there is no fluctuation; if the general health and appetite be good; we may suspect pregnancy. Yet, in the pregnant state, it sometimes happens that the uterus will rise on one side rather than the other; and in encysted dropsies the swelling is not general. Such circumstances occasion much doubt and uneasiness; for, in one case, the physician's character, in the other, the woman's, is at stake. In such situations we must rest in suspense, carefully watching the progress, and attending to the state of the breasts, and other symptoms of pregnancy. When the swelling has reached near the umbilicus, the round circumscribed tumour of the uterus can be distinctly felt, and can rarely be mistaken. We have, however, a recent instance before us, to show that mistake is not impossible. If there is still any room for hesitation, we should wait longer, nor proceed to active measures till the tumour has continued so long as to prevent any further doubt of its nature.

It happens also, as we have said, that married women who have no wish for concealment, or women of decidedly bad characters who cannot be injured by an illegal pregnancy, have sometimes equivocal complaints of this kind. Such doubtful cases chiefly occur at the change of life, when the cessation of the courses gives a colourable appearance to the suspicions of pregnancy. In this case, the general health, and the state or progress of the tumour, will enable us to decide; but we would deprecate any hasty decision of its being dropsy, and any violent remedies, till a sufficient period has elapsed to destroy the slightest suspicion of a pregnant state.

There is one other disagreeable situation for the practitioner; we mean, when dropsy and pregnancy are combined. If a married or an abandoned woman has dropsy, it is not impossible but that she may be also with child. The menstrual discharge will sometimes continue during the whole of pregnancy; and, in such circumstances, all suspicion sleeps. Yet the state of the breasts, an areolâ round the nipple, the capricious appetite, or the morning sickness, will give the alarm. These circumstances should be always attended to, and will suggest the necessity of caution. Every caution, however, has failed; and, in one instance, within our

own knowledge, during the operation of a drastic purgative, a premature delivery came on, though every possible attention had been paid to the diagnostic symptoms.

Yet, again, a married couple anxiously wish for a child, and the lady begins to swell. Woe to the practitioner who shall announce that she is in a dropsy! Whatever the circumstances or his opinion be, he must be cautious of opposing openly the wish; he must watch with care till the continuation of the complaint will assist the discovery of the unpleasing truth; while, by safe but sufficiently active medicines, he can prevent the dropsy, should it be so, from gaining ground; and he will reflect that she may *still* be pregnant. In the worst circumstances of general health, also, a woman is sometimes with child; and, when dropsy would naturally occur, it is not an unpardonable error to consider any tumour in the abdomen as such. The physician, however, in every case of supposed ascites, should be guarded with the most unremitting caution.

Tumours of the abdomen may sometimes be mistaken for dropsy, but the hardness and irregularity will soon discover the nature of the complaint. Wind, either in the cavity of the peritonæum or in the intestines, is distinguished by the elasticity of the tumour, the want of fluctuation, and, in the last instance, by its variable state, and the relief felt from the occasional discharge of flatus.

The cure of ASCITES is a difficult task; and indeed the best concerted plans generally fail, as the disease is often a symptom of a decayed constitution, of the *vis vitæ* no longer able to support the requisite equilibrium of discharges and absorptions. When dropsy follows frequently occurring paroxysms of asthma, it is generally found to arise from obstructions to the returning blood, in consequence of ossifications on the right side of the heart: where shall we find the solvents of these bony substances? When the disease proceeds from obstructed liver, we must reflect, that the veins from almost all the chylopoietic viscera center there, and that the whole venous system of the abdomen is consequently obstructed: where shall we find aperients and deobstruents of sufficient power to remove the obstacle? When, from long continued excess, the whole system is weakened, where shall we find the restorative to renew youth, to give fresh vigour, and new powers to the whole machine, to approach the art of conferring immortality? Yet medical authors draw their indications, and speak with confidence of their remedies: the inexperienced student believes, and is disappointed; is credulous, and soon becomes sceptical. It is our business to guard against each extreme; and to add, that, though the cure of dropsy is difficult, and often hopeless, yet that we can almost always alleviate, and sometimes cure.

If the indications to diminish exhalation and increase absorption could be followed, we might be more sanguine. The most frequent part of our duty, however, is to *increase other evacuations, that nature may supply the defect, from the accumulated fluid of the cavities.*

If, however, we would diminish exhalation, we should employ cordials and tonics to support the action of the extreme vessels which convey the blood back to the heart. In this way we may suppose mercurials of use; and, it has certainly happened, that, in cases where

there was no suspicion of obstructed liver, calomel and mercurial frictions have been of great service. Where such obstructions do occur, the use of mercurials is less equivocal. The employment of warm tonics is referable also to this head; and perhaps the oleum terebinthinæ and the mustard, may produce, in part, their effect from their stimulus. The more modern French physicians usually combine tonics with their evacuants, perhaps with propriety, except in cases of hydrothorax. Dr. Magennis has published in our own language an account of his practice, which induces us to mention his name; but various observations occur in the *Mémoires de Médecine* of the same tendency. Dr. Magennis gave the myrrh and ferrum vitriolatum with the squills; and Cornette and others give with the evacuants, bark and cordials. Bacher's tonic pills are referable to this head. The basis was black hellebore, whose acrimony he attempted to correct by repeated affusions of spirit of wine, and afterwards by Rhenish wine. The latter was supplied in proportion as it was imbibed by the roots, so as to continue covered, nearly six fingers breadth above them, for forty-eight hours. The whole was then boiled for half an hour, and the wine pressed out. The process was repeated, and the fluids added, inspissated to the consistence of a syrup. One part of the extract is then mixed with two parts of boiling water, and the whole again inspissated. This preparation of the pills is, he thinks of great importance, as the substances combined to form a mass must be both inviscating and soluble in the stomach. For this purpose an ounce of the extract is united with an equal quantity of an inspissated solution of myrrh, and the whole made into a mass with three drachms and a scruple of powdered carduus benedictus. The pills contain a grain and a half each of this mass. He calls them evacuant and tonic; but they seem to act chiefly as evacuants. In his hands, and in those of Dr. Daigman, they succeeded: with almost every other practitioner they have failed; and are now little used in this country, though they maintain their credit on some parts of the continent.

In fact, therefore, as we have said, our chief object is to increase the serous evacuations, in order to assist absorption. This is most successfully performed by increasing the evacuations from the mouth and salivary glands; from the skin; from the stomach; from the intestines, and the kidneys.

Some few solitary instances of spontaneous salivation proving a remedy for dropsy, have led to the use of mercury for this purpose. Yet as mercurial salivation is not only a severe remedy, but a frequent cause of dropsy, it has not been followed. When obstructed perspiration is a cause, sudorifics have been employed; yet these weaken the system, in general, too much, if persisted in for the time required in this disease. We have, however, before us a man who laboured under a dropsy twenty-five years since, from working in a river: all the remedies failed till he took Dover's sudorific powder, which succeeded, and he has had no return. In this long interval it is, however, a solitary case, though the same plan has been often tried.

Some instances also of water having been evacuated from the stomach, have led to the use of emetics. These are indeed remedies of importance for promoting absorption, independent of the evacuation they pro-

duce. In the general cases of dropsy, they are inadmissible from the debility of the patient, and from their preventing a proper supply of nourishment or cordials. We find few instances of their use, and fewer of their efficacy.

The discharge from the intestines we consider as of the greatest service in dropsy; and, indeed, we cannot say that the cure has in any case properly succeeded where this discharge has not accompanied the others. Sydenham advised purgatives every day, unless too great weakness prevented their use. In the operation of purgatives, however, this distinction must be made. If accompanied by violent colics, and an inconsiderable or a disproportioned discharge, weakness is the consequence, and the remedy must be discontinued; but if they operate without pain and inconvenience, and if the stools are watery, whatever the number may be, weakness does not follow. It should be the physician's business, then, to attain this end by his choice of the medicine. The saline purgatives are the most obvious ones; but in general the quantity necessary, and the large proportion of fluid to convey them, prevent their exhibition. The sal diureticus, the salt most generally employed, has been perhaps preferred from its name, and indeed seldom acts without assistance as a purgative. The cremor tartari is more common, and has been highly commended; yet, alone, the necessary dose is too large, and we have been induced to join with it a proportion of jalap, a medicine preferred as, in small doses, sufficiently mild, and as supposed to combine diuretic powers. Yet, with many persons, this medicine must be still further quickened; and a convenient addition is the gutta gamba.

In the list of cathartics, we find the more acrid kinds distinguished by the name of *hydragogues*, expellers of water. This is, indeed, the characteristic of many of the resinous purgatives; so that what we have said of the milder kinds is rather cautionary than strictly necessary. Of those hydragogues, the elaterium (the inspissated juice of the wild cucumber), the colocynth, the gutta gamba, are the chief; and next in order are the scammony, the jalap, and the seneka. A formula of Dr. Dover is powerfully hydragogue; it consists of four parts of scammony; crude antimony, and sulphurated steel, of each one part: and from a scruple to half a drachm is a powerful dose. Of these, the elaterium and the colocynth alone appear too stimulant. They have seldom succeeded in procuring watery stools without greatly irritating and weakening the patient. Gutta gamba succeeds better; but this beyond a grain or two produces sickness, languor, and faintness: and it seems more useful in rendering other purgatives active than given alone. Scammony holds its rank as an ingredient in Dover's formula, and is not often employed alone. The seneka is highly recommended by Dr. Milman; but he proposes only half an ounce or six drachms of the root to a pint of the decoction, instead of an ounce formerly directed by the Edinburgh college; and his proportion is, in the late edition, adopted. It is an active purgative, and said also to be diuretic. The jalap is the remedy most commonly employed. It is remarked by Lewis that the watery infusion is diuretic, and the spirituous tincture cathartic; and this has been repeated by every author, without having tried the experiment. On trial we have found no such effect from the infu-

sion; and the tincture of jallap, or its resin; has appeared to us the best preparation. Combined with soap, in pills, the resin has not appeared too virulent.

One observation arises on an examination of the effects of purgatives, viz. that the more active ones, which excite languor and nausea, are the most useful; apparently the relaxation thus produced, assists their purgative power, as a small proportion of emetic tartar greatly increases the action of the resinous purgatives in general. The diuretics also, which are most useful, possess a similar effect; and the squills seldom succeed in increasing the discharge of urine to any degree, till raised to a nauseating dose. Another remark, which we may suggest is, that, during the action of hydragogues, the secretion by the kidneys is scarcely in any instance increased; yet the patient recovers strength, appetite, and spirits: and indeed we have found, in the happiest recoveries, that the urinary discharge is not increased, till the load of water is in a great degree removed. A similar observation will recur when we speak of the operation of the paracentesis. Amidst these numerous advantages, it is with some surprise that we find a man of judgment and experience, Dr. Fordyce, so adverse to cathartics; and we suspect, that a little prejudice prevented him from using them with so much freedom as would show their utility. When we reflect also, that one of the most frequent causes of dropsy, obstructed liver, is greatly benefited by purgatives, our temptation to employ them will be increased.

As we pretend not to have enumerated all the purgatives employed at different times, but only to appreciate the value of the more useful ones, so, in the enumeration of *diuretics*, we shall follow a similar plan. Of these, the principal is the squill, with the rest of the onion tribe. It is, alone, a host: and could we render it a purgative as often as we find it injuriously so, viz. in pneumonia, we should perhaps want no other medicine for all curable dropsies. In every form, dry or fresh, in vinegar or tincture, it succeeds in the greater number of cases; but its nauseous taste renders pills the most convenient mode of exhibiting it; and the dry powder, which retains all its activity in a moderate bulk, best adapted for the purpose. With cream of tartar, and a small portion of jalap, it is highly useful, as combining a diuretic and purgative effect; and, with the resin of jalap and gutta gamba, in pills, its utility is almost unrivalled. Of the other vegetables of the onion tribe we use only the juice of leeks, which, though nauseous, is said to be often successful. The *colchicum autumnale* is apparently the next in power: we have sometimes thought superior, for it has succeeded where squills seem to have failed. The broom is a very useful diuretic; and the broom ashes, as combining the alkaline salt with the essential oil of the vegetable, have been highly commended. The alkaline salts themselves are useful in this way, though of weaker power. The broom seeds formed the secret remedy of Lemery; but these are acrid, and in general unmanageable.

The other diuretics are, the *lactuca virosa*, the juniper berries, the taraxacum, the nicotiana, and the fox glove. The first rests on the authority of Dr. Colin of Vienna, for the medicine has been rarely given in this country. The juniper berries are well known, and the diuretic effects of gin (from *Junipero* in Italian) suffi-

ciently understood. The taraxacum is still more powerful; and the tobacco, especially when its alkaline salt is employed, appears, from Dr. Fowler, to be a very active, useful medicine, meriting much more attention than it has received. The fox glove requires a longer discussion. It is arranged in a poisonous and suspicious order with the nicotiana, &c.; and in many instances it seemingly shows a deleterious power. In dropsy, death often suddenly seizes the patient; but we have thought this sudden termination still more frequent when the fox glove has been taken. It is, however, a remedy of considerable power and utility. The weakness, the nausea, and the affection of the head, which often follows its exhibition, would point it out as chiefly useful to the strong and active. On the contrary, however, the weak, languid, worn out constitution is chiefly benefited by the fox glove; and the discharge of urine, which it occasionally produces, is astonishing. Every part of the plant is equally effectual; but the leaves are generally employed, and the dry powder is the most useful and certain preparation. We fear, however, that the injuries resulting from it have greatly overbalanced the benefits.

Diuretics from other sources have been numerous. From the animal kingdom we have received the cantharides, which, with some physicians, have been a favourite remedy. We own, however, that in our hands they have not produced any diuretic effect, nor have we recognized their activity till they have reached the neck of the bladder. Some other species of the meloe have been supposed also diuretic, but experience has not decided on their virtues.

The chief remedy of the mineral kingdom is nitre, whose powers are not considerable; and chemistry has furnished us with the sweet spirit of nitre, an æthereal fluid, which in slight cases is often successful. The turpentine also, formerly mentioned, is a preparation frequently and generally useful as a diuretic.

Some other modes of relief remain. A powerful one is friction; and friction, with olive oil, has been employed since the time of Celsus, though the oil, by general consent, is considered as useful only to prevent excoriation. Perhaps the friction with camphorated oil has no very different effect; and when the external application of mercurial ointment has been found useful, friction may have had some share in the success. Mustard and horse radish have been ordered without any determinate view, and have been attended with no very striking success. The mustard seed unbruised, often swallowed in dropsical and paralytic complaints, acts only as a gentle laxative.

Two important subjects remain: the first is the propriety of indulging diluted liquors, and the second the operation of the paracentesis. For nearly two hundred years it has been common to prohibit the use of fluids in dropsy; and the reason probably was, that as an excess of diluents sometimes brought it on, so they might continue or increase it. We recollect a case in the Medical and Physical Essays of Edinburgh, where a salt herring was ordered without any liquid: the thirst was burning and intolerable; but after a time it ceased, and a flow of urine came on. In such a violent agitation, nature might have exerted her powers to supply dilution; and the absorption, once commenced, might have continued. The experiment is, however, too

violent to be repeated; and, in a less degree, the abstaining from drink would probably be useless. In fact, the prohibition is of a modern date: it was not the practice of the ancients; it is not of the most experienced physicians of the present day. If a regular course of evacuations is pursued, the fluid taken in will not at least be injurious: it may be beneficial; for watery liquors verging to the kidneys may excite their action, and thus contribute to the absorption. It generally happens, that, during a course of purgatives and diuretics in dropsy, occasionally refusing or supplying drinks, occasions little alteration in the progress of the complaint: if there is any change, the cure is accelerated; and we think we have seen, that cathartics and diuretics have not had their proper and appropriate effects till diluent drinks have been allowed. The prejudices of patients have sometimes occasioned their rigorously abstaining from drink, but we have never found the cure advance more rapidly. Dr. Milman has considered the subject at length, and is of this opinion; and we formerly examined in a chronological series the opinions of the ancient physicians on this subject, and found them speaking the same language; but this historical research would be too extensive for the present work.

The operation of the paracentesis has been in general too long delayed. If there is a considerable accumulation of fluid in the abdomen, and the different evacuations have no decided or powerful effects, it should be attempted early. When the load is removed, medicines, which were unequal to the discharge of so large a quantity, may prevent its again accumulating; and, at all events, the removing the pressure from the kidneys appears to facilitate the action of their vessels: even a spontaneous discharge of urine has been the result; and diuretics certainly answer with greater certainty and effect after the former burden is taken off. Dr. Fothergill recommends the operation so soon as the degree of distention removes all fear of wounding the intestines. Dr. Hunter leans to the same opinion; and Dr. Baker urges it more confidently.

Yet, in directing the operation, we should examine several questions with great care; and the neglect of this enquiry has contributed to its disrepute. The general contents of dropsical swellings are serum, not essentially different from the serum of the blood; but we sometimes find it lymph from a rupture of a lacteal; sometimes purulent matter from a supposed previous inflammation; sometimes the peculiar serosity of hydatids. The two former may perhaps be distinguished by a want of freedom in the fluctuation; yet this criterion is necessarily uncertain; and, in some of the less sensible viscera, suppuration proceeds with so little fever, that we have no reason for suspecting the existence of purulent matter. Added to this, it is by no means certain that this peculiar fluid may not be secreted from a surface not previously inflamed. De Haen was of this opinion; and we have, we think, seen two instances of purulent matter in the abdomen, apparently secreted from its parietes without previous fever. When the fluid is the lymph effused, in consequence of a rupture of a lymphatic, there is no particular danger from the operation; but should the accumulation recur, perhaps some delay may be necessary, as the pressure of the effused fluid may contribute to prevent further effusion,

and heal the wound. Where the fluid is purulent, the worst consequences result from the operation, as the access of air soon occasions putrefaction; and, though some present relief is obtained, we have seldom seen such patients long survive the operation. It would be an object of importance, therefore, to be able to ascertain its existence; but there are no discriminating symptoms, except the fluctuation and the apparent causes.

When the accumulation is from hydatids, there is no peculiarity in the symptoms, and indeed no danger from the operation. These may be suspected in dropsies which attack the young, whose viscera are sound; and these are cases which often recur for a time, and then the disease disappears for long intervals, perhaps wholly. The cause is ascertained by some small pieces of apparent membrane passing through the trocar. See HYDATIDS.

One other kind of dropsy, the *encysted*, requires peculiar attention with respect to the propriety of performing the operation. It is distinguished by the tumour appearing first locally; by the fluctuation feeling distinct only in some particular directions, or parts of the abdomen; and in the early stages, by some irregular hardness on deep pressure. These accumulations of water generally begin in the ovaria, and we suspect are always occasioned by hydatids. We know not, however, that if the sac is pierced by the trocar that there is any peculiar danger; but in all these instances the relief is temporary only: a dropsy originating in the ovarium is seldom cured. After the operation, the existence of a cyst is ascertained by the abdomen not being completely emptied; for some water is always at the same time accumulated in the abdomen; and if the instrument has penetrated the cyst, the other water remains; if not, the cyst is still unemptied. In either case it may be felt on pressing the abdomen. In passing the trocar, if there is a cyst, the resistance is unusual, and the pain violent; but we have known a cyst penetrated, in repeated operations, without danger. See PARACENTESIS.

When the duplicature of the peritonæum is the seat of the *ascites*, tapping is alone the remedy. For the relief of occasional symptoms see HYDROPS. See Milman on the Dropsy. Leake's Medical Instructions, edit. 5. Cullen's First Lines, vol. iv. and White's Surgery, 304.

ASCI'TES UTERI'NUS. See HYDROPS UTERI.

ASCI'TICUS, (from *ascites*). One who labours under an *ascites*.

ASCLE'PIAS, (from Asclepius, its inventor; called also *hirundinaria*, *contrayerva Germanorum*, *vincetoxicum*). TAME POISON, SILKEN CICILY, and WHITE SWALLOW WORT. *A. vincetoxicum* Lin. Sp. Pl. 314.

It resembles the apocynum, or dog's bane; and like it yields a milky juice.

The roots, when fresh gathered, smell like the root of valerian, but lose their odour by drying: chewed, they are sweetish at the first, then bitterish. In doses from ʒ i. to ʒ i. it is sudorific and diuretic. In these characters it hath been so commonly used by the Germans as to have obtained the name of *contrayerva Germanorum*.

It is said to be useful as an emmenagogue; and has been employed, though with little success, in dropsy:

from its connection with many poisonous plants, it is, however, suspicious, and to be used with caution.

ASCLEPIAS ASTHMATICA, Lin. Supplem. 171. Willdenow, Sp. Pl. v. i. p. 1270. This is a plant from the island of Ceylon, and is slightly emetic and cathartic. Its chief use, as the name indicates, is in pituitous asthmas, and is given in decoction or syrup.

ASCLEPIOS, (from the same). The name of a dried smegma described by P. Ægineta; of a troche in the writings of Ætius; and a collyrium in Galen; called ATHENIPHUM, from its author Athenippus.

ASCLITES. See ASCITES.

ASCO'MA, (from ασκος, a bottle). The eminence of the pubes at the years of maturity.

A'SCOS, (from ασκυτος, leather). A BOTTLE. They were formerly made of leather, and Hippocrates used to apply them, when filled with hot water, to pained parts.

ASCYROIDES, (from ασκυρον, and εidos, forma). A species of the ascyrum.

A'scyros, A'scyrum, A'scyrus; probably from Σκυρον, the city Scyrum, where it abounds. See ANDROSÆMUM.

ASDE'NIGI. See HÆMATITES.

A'SE, or As'se, (from αδω, nauseo). Hippocrates by these words means a loathing of food, from accumulations in the stomach.

A'SEB. See ALUMEN.

A'SEF. See HYDROA.

A'SEGEN. See SANG. DRACONIS.

ASE'LLI; also called millepedes, polyhedes, cutio, cyamus; multipedes; cubaris; centipedes: SLATERS, HOG' LICE, CHURCH BUGS, SOW BUGS, and WOOD LICE.

These are insects, according to Linnæus, of the class aptera, and genus oniscus. It comprehendeth fifteen species. One species is the wood louse, and the variety employed is of a bluish colour, which, if touched, rolls itself up in a rounded form. They are found under stones and logs of wood, in cold, moist places; and the pale brown, and the bluish black sorts are indiscriminately used. Those found in vaults are said to contain the largest proportion of salts, and most esteemed.

The London college directs them to be dried by suspending them in a thin canvas bag, placed within a covered vessel, and over the steam of hot proof spirits, that, being killed by the vapour, they may become friable.

The taste of these insects is sharp and pungent, and they are supposed to possess an alkaline quality, and to be diuretic.

They are prescribed, both fresh and dry, in hepatic, and other visceral obstructions; in pituitous diseases of the chest, and suppression of urine; the dose in powder, from ℥ i. to ℥ i.; in an expressed vinous infusion, ℥ ij. repeatedly. They have been swallowed alive in great numbers daily; and though reckoned diuretic, the effects usually attributed to them are doubtful. From fifty to one hundred are eaten alive; or infused in wine and pressed, half an ounce is taken for a dose.

ASE'LLUS. The COD FISH; it is called also cabellau, morhua, molva, and the KEELING. This belongs to the genus gadus Lin. and includes the

whiting, the haddock, the whiting pout, the sea pike, and some similar fish. See ALIMENT.

A'SEMOS, from α, neg. and σημα, a sign). An epithet applied to events that fall out contrary to all appearance, and without any manifest cause. A crisis happening beyond hope.

A'SEPTA, (from α, neg. and σηπω, to purify). Unconcocted or undigested.

ASH. See FRAXINUS.

ASH, MOUNTAIN. See SORBUS.

ASH, POISONOUS. See RHUS.

ASH, BITTER. See QUASSIA.

ASHES. A term generally applied to the residue of combustion; generally limited to vegetable ashes, though sometimes applied to mineral calces. Vegetable ashes differ according to the degree of heat to which they have been exposed. With a moderate heat they contain much charcoal; but with a stronger, a white light earth, with some alkaline salts, and perhaps a little oil, only remain. In this state we find them in commerce, under the name of potashes, pearlashes, &c.

In these ashes the minuter modern chemistry will discover a small portion of magnesia, a little iron, and perhaps some phosphoric salts, with a small quantity of lime; but these have little reference to medicine. They must all be separated before the ashes can be employed as a remedy.

ASHES, ANIMAL. These are more refractory than the vegetable ashes, as containing a larger portion of phosphoric salts, but the only substance of this kind used in medicine is the cornu cervi calcinatum, which owes all its virtue to a little remaining mucilage. The lixiviated salts of bones are used in chemistry to form cupels for assaying metals, as they resist vitrification from the calces of lead.

ASIA'TICUM BALS. The BALM of GILEAD. See BALSAMUM.

A'SIGI. See ÆRUGO ÆRIS.

ASI'MION. An ingredient mentioned by Myrepus, but not known.

ASI'NGAR. See ÆRUGO ÆRIS.

A'SINUS, (from α, neg. and σινος, hurtful). The ASS. Its milk is in much esteem as a medicine. See LAC.

ASITI, ASI'TIA, (from α, non. and σιτος, food). Those are so called who take no food for want of an appetite. See ANOREXIA.

A'SJOGAM, (Indian). A tree growing in Malabar and the East Indies, whose juice is used against the colic. Raii Hist.

A'SMIAR. See ÆRUGO ÆRIS.

ASPADIA'LIS, Ischuria. A suppression of urine from the urethra being imperforated. See ISCHURIA.

ASPA'LATHUM, (from α, priv. and σπaw, to draw out,) called also agallochum. CALAMBAC WOOD. It is brought from the East Indies; it is of a bituminous and fatty kind, or resinous, and of a bitter taste. It is sold very often for the agallochum, having similar virtues, and is probably the same. See AGALLOCHUM.

ASPALATHUS, (from α, priv. and σπaw, to draw out, because its thorns are not easily drawn out when they have entered,) called also Rhodium lignum, dipsacon, lignum rosæ odoræ, lign. thuris, erysisceptum, Rhodina radix, Rhodium, or ROSE WOOD. Genista

*Canariensis* Lin. Sp. Pl. 997. Nat. order *papilionaceæ*.

*Rose wood* is the root or the wood of a thorny shrub, brought from the Canary islands in long crooked pieces, externally of a whitish colour, internally of a deep yellow, with a reddish cast. The heaviest and the deepest coloured is the best.

When rubbed or scraped, it smells like roses. To spirit of wine it gives out all its virtue; but of this tincture nothing rises in distillation except the spirit, hardly affected with the smell or taste of the wood; water also extracts its virtues, and carries them with it in distillation; resembling the smell from damask roses. Fifty pounds weight of good wood afford one pound of essential oil, which is used as a perfume; it is weaker than the oil of roses, but of the same odour.

An agreeable cordial tincture is made by macerating  $\frac{3}{4}$  iv. of this wood with a pint of rectified spirit of wine: from ten drops to a tea spoonful is a dose.

**ASPARAGI.** The young shoots, or first tender sprouts of an herb from the ground, before any leaves unfold themselves.

**ASPARAGUS, SPARAGUS; SPERAGE, and SPARROW GRASS.** *Asparagus officinalis* Lin. Sp. Pl. 448.

It is a perennial plant, chiefly used as aliment; in the spring a number of shoots appear, the tops of which are named *turiones*, and these only are eaten. It grows wild in Cornwall and some other parts of England.

Though confined to the kitchen, it affords very little nourishment; a decoction of the roots is diuretic, but a strong infusion of them is preferred. It imparts a fetid smell to the urine, which is corrected by an acid.

**ASPASIA.** The name of a constrictive medicine for the pudenda mulicbria, consisting of wool moistened with an infusion of galls.

**ASPER.** A small river fish found in the Rhône. *Perca asper* Lin. It is so named from the roughness of its scales and jaws. It is good food, and very nutritious.

The oil of *asper* is commonly enquired for as a means of catching fish with ease and certainty. It is probably the oil of ospray which is meant, for there is a fable, that this bird, as it flies, drops something on the surface of the water, by which the fish is allured. There is, however, no such oil, and the oil of box is usually sold for it.

**A'SPERA ARTERIA,** (from *asper*, rough, and *trachea arteria*, from *τρυχός*, rough,) so called from the inequality of its cartilages. The WINDPIPE. It is formed of the LARYNX, the BRONCHIÆ, and the VESICULÆ MALPIGHIANÆ. The LARYNX hath five cartilages, forming the upper part of the *aspera arteria*: the first is the THYROIDEA PELTATA, or CLYPEALIS; resembling a shield, placed just under the basis of the os hyoides, of a quadrangular figure, and stands in the anterior part of the neck, where the pomum Adami is seen; the lateral portion runs back, and ends in two processes; one of which runs up, the other down, and are connected to the os hyoides: the second is the CRYOIDEA; called also *cymbolaris cartilago*; it stands beneath the preceding, is of an annular figure; the back part stands between the two processes of the thyroid cartilage, to which it is articulated. It is nar-

row before, thick behind, and serves as a base to all the other cartilages; being, as it were, let into the thyroids. By its means the other cartilages are joined to the trachea, on which account it is immoveable. The third and fourth are the two ARYTÆNOID cartilages, joined to the superior and posterior parts of the cryoid by peculiar articulations, that the glottis may the more readily be opened and contracted; each of these has a protuberance for the insertion of the muscles which stands over the cryoid cartilage, and each has a process where the ligament of the epiglottis is fixed; they are small at their base, and large at their upper part. The fifth is the EPIGLOTTIS, shaped like the leaf of a plant; Winslow says that of the purslane. It is joined to the anterior and superior part of the thyroid cartilage, over which it appears erected behind the root of the tongue, to which it is connected by ligaments fixed to the cornua of the os hyoides; it is also connected with the arytænoid cartilages. It covers the glottis whilst we swallow, to prevent any thing getting into it. These form the beginning of the *aspera arteria*, which, passing down from behind the tongue into the lungs, is situated before the œsophagus, and surrounded, laterally and before, by the thyroid gland. It enters the cavity of the thorax behind the upper part of the sternum, where it is crossed by large vessels which run up to the head. At about the fourth vertebra of the back it divides into two branches; that which goes into the left is divided into two; these branches are called BRONCHIÆ, and are divided again into numberless other ramifications, which are distributed through the substance of the lungs, and which consist of cartilaginous segments and contractile membranes; then they are expanded into oblong vesicles, after having lost their cartilaginous nature, called VESICULÆ MALPIGHIANÆ. They are supposed to terminate in vesicles like clusters, which adhere to the small bronchial ramifications, constituting the chief part of the lungs. The use of the bronchiæ is to afford a passage for the air into the lungs, and a free return from them, with such superfluous matter as is capable of combining with it. The *aspera arteria* is cartilaginous forward, and membranous behind.

When any small substance falls into the trachea, it occasions much uneasiness until it is thrown up. To assist its discharge, Ætius commends sternutatories; others, expectorants and emetics; but the cough, which nature excites, is the only effectual mode of relief.

**ASPERA'TA.** See ASPERUM.

**ASPERA'TUM SPECILLUM,** (from *asper*, rough, and *specio*, to examine). See BLEPHARÔXYSTUM.

**ASPERGULA,** (from *asper*, rough). See ASPERULA.

**ASPER'SIO,** (from *aspergo*, to sprinkle). SPRINKLING. See CATAPLASMA.

**ASPERU'GO, ASPE'RULA;** called also *aspergula*, *apharine latifolia*, *hepatica stellata*, *matrisylvæ Germanica*, *rubeola montana odora*; woodrow, and wood-roof. *Asperula odorata* Lin. Sp. Pl. 150.

It is a low umbelliferous plant, whose taste is a little austere. It imparts its flavour to vinous liquors, and is commended as a cordial and deobstruent. It is also a name for ASPERINE; RUBIA SYNANCHICA.

**ASPERUM, ASPRUM,** *asperatum, aspretulo*, (from

*asper*). ROUGH. An epithet applied to bodies with uneven surfaces. Galen observes, that every rough body is uneven, but every uneven body is not rough; and that roughness is occasioned by too great dryness, or from acrimony.

ASPHALTI'TIS. A name of the first vertebra of the loins. See CASTELLI LEXICON.

ASPHALTOS, ASPHALTUM, (from *Ασφαλτις*, a lake in Judea where it is produced). See BITUMEN.

ASPHODE'LUS, (from *σποδῆλος*, *ashes*, from the ashes of the dead, because the herb was formerly sown upon the graves of the dead). The ASPHODEL.

ASPHODE'LUS A'LBUS. *A. ramosus* Lin. Sp. Pl. 444. WHITE ASPHODEL. Also called *hasta regia*, *Bernhardi testiculus*, *anthericum*, *affodilus*, *iphion*, *erizamba*, KING'S SPEAR, and YELLOW ASPHODEL.

The asphodel roots resemble an acorn; are acrid, heating, and diuretic, when fresh, and mucilaginous when dry.

These plants are natives of Italy, France, and other warm parts of Europe. The fresh roots are commended in the form of a cataplasm, to be applied to scrofulous swellings.

ASPHY'XIA, (from *α*, neg. and *σφυξίς*, a pulse, from *σφύζω*, to leap, or beat, like an artery). It is so named, because the pulse is not perceptible to the touch; but the characteristic signs of this disease are, the symptoms of apparent death, for the most part, suddenly coming on. If a patient, gradually growing worse, at length dies, that state is not an asphyxy, for this term must be confined to a disease from which a patient may recover. All the causes of death which do not wholly destroy the irritability of the muscular system, may be considered as the sources of asphyxia. Syncope for a time assumes its form, though the characteristic appearances of death are seldom observed in any great degree. See LIPOTHYMIA, APOPLEXIA, SYNCOPE, SUBMERSIO, SUSPENSIO, and CONGELATIO.

It is however necessary to remark, that those who appear to die suddenly should be kept till they begin to grow putrid and offensive; but if signs of an aneurism being burst, or of an apoplexy, or of an inveterate vomica, have preceded this sudden death, we can certainly judge whether it is in reality death, or only an asphyxy. See Lancisius, Winslow, and Bruhier, on this subject.

A'SPIC. See LAVANDULA.

ASPIDI'SCOS, (from *ασπίς*, a buckler). By metaphor it was applied to the sphincter muscle of the anus, as we are informed by Cœlius Aurelianus, which was so called from its shape. See SPHINCTER ANI.

A'SPIS. The ASP. A venomous kind of serpent, of which Galen reckons three species. Paulus Ægineta, in lib. v. cap. xviii. says, that amputation is the only remedy when a limb is bit; and cutting away the whole of the wounded flesh, where amputation cannot be performed.

ASPLE'NIUM, (from *α*, neg. and *σπλήν*, the spleen,) because it was said to remove disorders of the spleen; also called *splenium ceterach*; MILT-WASTE, and SPLEEN-WORT. It is the *asplenium ceterach* Lin. Sp. Pl. 1538. SPLEEN-WORT.

The leaves are similar to maiden-hair, as a pectoral; they are diuretic; and used in infusion, are supposed to clear away sabulous matter from the urinary passage.

The taste is somewhat austere, and it has been thought useful as a tonic in cachexies.

ASPLE'NIUM TRICHO'MANES, Lin. Sp. Pl. 1540. See ADIANTHUM NIGRUM.

ASPLE'NIUM SCOLOPE'NDRIUM, Lin. Sp. Pl. 1538. See LINGUA CERVINA.

ASSABA, a shrub found on the coast of Guinea. Its leaves are boiled in water and supposed to cure buboes.

A'SSAC, (Arabic word A'SSAK). See GUM AMMONIACUM.

A'SSALA. See NUX MOSCHATA.

ASSANE'GI. The powder that falls off from the walls of salt in the salt mines.

A'SSANUS. A weight consisting of two drachms

ASSARABA'CCA. See ASARUM.

ASSARTHRO'SIS. See ARTICULATIO.

ASSA'TIO, ASSATION, or ROASTING, (from *assare*, to roast with fire). Frying, toasting, broiling.

ASSATU'RA. A species of any thing just removed from the fire after roasting.

A'SSE. See ASE.

A'SSERAC. See ASSIS.

ASSERVA'TIO, (from *asservo*, to keep carefully). See CONSERVATIO.

ASSI'DENS SI'GNUM, (from *assido*, to attend). An attendant sign, usually accompanying a disease, but not, as the *pathognomonic*, inseparable from it.

ASSI'DUUS, (from *assideo*, to attend). See CONTINUA FEBRIS.

ASSI'MILO, to ASSIMILATE, (from *ad*, and *similis*, to make like to,) as when what we eat is converted into juices similar to those of the animal body. It is also used in another sense, when the morbid matter of any disease converts the whole or part of our juices to their specific nature; our juices are then said to be assimilated to the nature of those morbid materials. See DIGESTION.

A'SSIS. A'SSERAC. The Ægyptian name for BANG, which see, and also CANNABIS.

ASSISTENTES, (from *ad*, and *sisto*, to stand near). A name for the prostate glands, because they lie near the bladder. See PARASTATE.

ASSI'TRA. See MANDARU.

A'SSIUS LAPIS; called also *asius* and *azius lapis*, ASSIAN STONE. These stones receive their name from *Ασσός*, a city of Troas, in the Lesser Asia, where they are found. They are of a tophous, soft, friable, and loose substance, with a powdery matter growing on them like meal, such as is seen on the walls of mills; it is called the FLOUR OF THE ASSIAN ROCK, and is seemingly an aluminous efflorescence. This flour consumes loose spongy flesh; hence called *sarcophagus carnivorous*: the stone possesseth the same virtue in a less degree.

ASSO'DES, (from *assare*, to burn). A continual fever, with a moderate heat externally, but inwardly much greater, insatiable thirst; perpetual tossing, nausea, loathing of food, watching, and raving. It is called by Sauvages *tritæophya assodes*; and is also arranged by Cullen under *tertiana remittens*. An account of fevers of this kind may be found in Huxham de Aëre, lib. i. p. 97. Lancisius de Noxiis Paludum Effluviis; and Morgagni Epist. 49. 14. See FEVER.

A'SSOS. See ALUMEN.

ASSUMINA. The name of a shrub which at once destroys the vena medinensis, and saves the trouble of drawing it out. It is found and used on the coast of Guinea. See Phil. Transactions, N° 232.

A'STACUS, or A'STACUS MARI'NUS, (from  $\alpha$ , neg. and  $\sigma\tau\alpha\zeta\omega$ , to distil,) so called from the hardness and dryness of its shell. The LOBSTER and CRAB hardly differ in any quality one from the other. They seem to contain a less proportion of azote than the flesh of quadrupeds, birds, and even of the amphibia, from the small quantity of volatile alkali obtainable from their substance. Notwithstanding which, they are supposed to neutralise acidity in the primæ viæ more perfectly than any other animal food of quadrupeds and birds. They afford, as we have said, (see ALIMENT,) a light easy food; but a small portion will sometimes occasion violent colic, and nettle rash, as occurs from eating muscles, attributed to idiosyncrasy of particular persons, perhaps to the food of the animal. Their flesh is best in summer. The black tips of the claws of the sea crab, and those stony concretions in the heads of the *astacus fluviatilis*, called crabs' eyes, form some of the absorbent preparations of the shops. See CANCER FLUVIA'TILIS, and OCULI CANCRO'RUM.

A'STACUS FLUVIA'TILIS. The CREVIS or CRAY-FISH. A mild insipid food, with few qualities to recommend it, or dissuade from its use.

A'STAPHIS. From  $\alpha$ , pleonasm, and  $\sigma\tau\alpha\phi\iota\varsigma$ , UVA PASSA; which see.

ASTA'RZOF. The name of an ointment, and of a mixture, which were used by Paracelsus. The first consisted of litharge, house leek juice, &c. The second, of camphor and rose water.

ASTCHA'CHILOS. So Paracelsus names a malignant gangrenous ulcer, which spreads from the feet upwards. Some call it *araneus*.

ASTER. An ancient medicine against defluxions or rheumatic pains.

A'STER, (from  $\alpha\sigma\tau\epsilon\rho$ , a star, from the likeness of its flower). STARWORT.

A'STER. OMNIUM MAXIMUM. See ENULA.

A'STER A'TTICUS. HYOPHTHA'LMOS. See ERYNGIUM.

A'STER PALU'STRIS PA'RVO FLO'RE GLOBO'SO. SMALL ELEABANE. See CONYZA.

A'STER PERUA'NUS. POTATOES. See BATTATAS CANADENSIS.

A'STER THALA'SSIUS, is named *Stella marina*. SEA STAR. A certain zoophyte or insect of the family of the *vermes echinodermes*. Hippocrates hath recommended it with brassica and sweet scented wine, against what is called the ascent of the uterus and hysteric pains; but it is wholly useless.

ASTE'RIAS, (from  $\alpha\sigma\tau\epsilon\rho$ , a star). STAR STONE. *Telesia asterias* of Haüy. Is a fossil gem, very hard, resembling half a globe, extremely full of black radiated appearances, resembling stars; from whence its name. In medicine it was considered as a charm against marks of the mother.

ASTE'RIAS. See GENTIANA.

ASTHENIA, (from  $\alpha$ , non. and  $\sigma\theta\epsilon\iota\varsigma$ , robur). EXTREME DEBILITY.

ASTHENIA ab HYDROCE'PHALO. APOPLE'XIA HYDROCEPHA'LICA. See APOPLEXIA.

ASTHENIA PANONICA. See AMPHIMERINA HUNGARICA.

ASTHENIA. General weakness, sometimes from excessive evacuations, but generally connected with visceral obstructions. In these cases it is attended with fever. If without fever, bark and other tonics are useful.

A'STHMA, (from  $\alpha\sigma$ , or  $\alpha\sigma\mu\iota$ , spiro, or rather  $\alpha\alpha\zeta\omega$ , *anhele*, to breathe short). This is an impeded and very laborious respiration, joined with inexpressible anxiety and straitness of the precordia, preventing a free circulation of blood through the lungs, arising from various causes, and threatening suffocation. The characteristic symptom of this disease is a *chronical*, and sometimes a *periodical*, difficulty of breathing; hence it differs from ORTHOPNEA, which is acute; from DYSPNEA, because that is continued.

This disease has generally been considered to be of two kinds; the *humoral*, *pituitous*, or *moist*; the *spasmodic*, *dry*, *nervous*, or *convulsive*. Both which are properly included in the subsequent definition. 'A difficulty of breathing, coming on at intervals, with a sense of straitness in the breast, and sibilating respiration; at the beginning of the paroxysm, attended with an uneasy cough, or no cough at all; towards the conclusion, a free cough, often attended with a copious expectoration of mucus. Dr. Cullen ranks this genus of disease in the class *Neuroses*, and order *Spasmi*, dividing it into three species.

1st. ASTHMA SPONTANEUM; to which belong the *orthopneæ spasmodica*, and *hysterica*, when there is no manifest cause, or any other disease attending.

2d. ASTHMA EXANTHEMATICUM, when it arises from the retropulsion of some acrid humours from the surface of the body.

3d. ASTHMA PLETHORICUM, when it is the consequence of some accustomed sanguinary evacuation suppressed, or a spontaneous plethora.—The *hypochondriac*, *arthritis*, and *venereal* species, are symptomatic only.

The attack of the *convulsive asthma* is sudden, and at its first appearance the fit is short. The symptoms which usually precede it are languor, flatulency, head-ach, sickness, pale urine, disturbed sleep, a sense of straitness and fulness about the pit of the stomach. In some cases there is an uncommon stupor, drowsiness, and heaviness. The fit is frequently observed to come on about one or two o'clock in the morning, or at any hour after the first sleep. The patient wakes suddenly, and feels a great tightness and constriction around the chest, with a difficulty of breathing, and an impediment to the free admission of air into the lungs. Both inspiration and expiration are slow, laborious, and accompanied with constant wheezing, particularly the latter. Great bodily anxiety always attends this disorder. As the lungs cannot be sufficiently dilated with air, the passage of the blood through the pulmonary vessels is not free. Hence the face, in full and plethoric habits, appears red and bloated, and the vessels of the eyes are unnaturally turgid. The action of the heart is greatly disturbed, as is evident by the weakness, irregularity, and increased quickness of the pulse. Dur-

ing the fit, the patient has generally a longing instinctive desire for cool fresh air, which always revives him. A small close room, with a fire in it, is extremely offensive, and all warm things, given internally, increase the flatulency in the stomach and bowels, which is always the most troublesome after a full meal. When the fit has continued a few minutes, half an hour, or an hour, it leaves the patient; his respiration becomes free and natural, his pulse slow and regular, his complexion puts on its usual appearance, and the bodily anxiety goes off. The urine is generally pale, and the skin somewhat dry before the fit, and during its progress; but at the termination of it, the urine for a day or two is high coloured, and deposits a sediment, and the skin feels soft and moist. This is the description of a first and moderate attack of the disorder. In some cases it appears in a more violent form, even at its commencement, and continues for several days before the fit terminates. Sometimes the patient will have one fit, and then remain free for many months. At other times fits come on for several nights together, the patient appearing almost perfectly well during the day, with his appetite and pulse natural. When the asthma once attacks, it seldom or never fails to recur, though the intervals between the fits are very uncertain; when rooted in the constitution, it often makes its attack in the spring and autumn. In many cases it attacks periodically once in ten days or a fortnight. Sometimes it occurs regularly at the full and change of the moon. Floyer mentions a case where the fits occurred for seven weeks together, and the patient was obliged to sleep in a chair; and from the strictest observations it is found, that there is no certainty nor regularity observable in the attacks of the asthma. The reason why the fits so often occur first in the night, is thought to be owing to the heat of the bed, and the horizontal posture in which the patient lies.

Relapses are commonly attended with an increase of the symptoms, and the vigour of the constitution is gradually impaired, till, by length of time, general or chronic weakness is induced. The difficulty of breathing in the fit arises to a much higher degree in these relapses, and the sensation of tightness over the breast is so great and distressing, that the patient feels as if he were bound with cords. His anxiety at this period is inexpressible, and he labours in respiration as if every moment would be his last. Severe vomiting frequently occurs, and the matter discharged is slimy and frothy, or of a greenish or yellow colour. The hands and feet are cold, and the patient is subject to palpitations and faintings. Cool fresh air becomes absolutely necessary. The eyes are prominent, the face is sometimes pale and sometimes high coloured, bloated, or livid; the pulse extremely weak, irregular, and even intermitting; there is a difficulty of swallowing, the patient can scarcely speak, cough, or expectorate during the fit, and the stomach and bowels are violently distended with wind. While thus labouring for breath, he is obliged to rise from his bed, he cannot bear even the weight of the bed clothes upon him. His shoulders are constantly elevated, to give the muscles of the chest their greatest power of action in raising the ribs in inspiration. At this time, too, the patient, though before costive, will frequently have a loose stool. When the violence

of the fit abates, and respiration becomes free, the cough returns, and the patient begins to expectorate phlegm, which is sometimes intermixed with blood. As soon as an easy copious expectoration takes place, it affords great relief, for the evacuation is made immediately from the parts affected, from the vessels which have been obstructed. This expectoration is one of the most certain signs of the abatement of the complaint, as it denotes the solution of the contraction of the bronchial air vessels; particularly if a moisture and softness of the skin, and a sediment in the urine, make their appearance. The blood which is spit up in this complaint proceeds generally from a rupture or dilatation of blood vessels in the lungs. In some cases, indeed, the quantity of blood which is spit up is in full habits very considerable, and at the same time accompanied with an abatement of the symptoms. But all free discharges of blood from the lungs, though they afford relief, are unfavourable signs, as they denote greater violence of the disease; during the course of which, the very efforts of nature to relieve are in themselves so alarming. The nose, too, will sometimes gush out with blood during the severity of the fit, from the obstruction given to the return of the blood through the pulmonary vessels into the left auricle of the heart. Thus in a short time the fit of the convulsive asthma goes off. In a course of years one fit succeeds another, and the disorder increases in the violence and duration of the fits, as well as in the frequency of their returns. The expectoration from the mucous glands of the lungs, which still continues to relieve at the termination of the fits, becomes itself a very troublesome symptom. These glands are relaxed, and the discharge of mucus greater than natural. Hence the bronchial or air vessels are frequently obstructed with phlegm, and from this cause the freedom of respiration is disturbed: the patient breathes with unusual difficulty, although his convulsive fits be absent. When he first wakes in the morning he has generally a severe fit of coughing, which continues till he has discharged the phlegm that provoked the cough, by preventing the free admission of air into the air vessels. Through the day, at different times, the cough still recurs, but with less violence; and in the evening it is often very teasing and distressing, especially on any sudden motion of the body, or in cold, damp, foggy weather, which obstructs the exhalation of the perspirable matter from the lungs. Thus the humoral asthma is united with the convulsive, and both together exist in the same patient.

THE HUMORAL ASTHMA is a disorder of the mucous glands of the lungs, in consequence of which they are relaxed, and the discharge of mucus, being unnaturally copious, obstructs the freedom of respiration. This kind of asthma is more constant; the convulsive more violent, and of shorter duration. The humoral asthma is more severe both with respect to the cough and difficulty of breathing in winter; but in summer, when the weather is warm, and perspiration free, it often disappears totally between the intervals of the fits of the convulsive asthma. The convulsive asthma, too, is sometimes severer in winter than in summer, especially when combined with the humoral, or with a catarrh. But it often happens that the warm weather affords little or no relief; nay, even in many cases it is observed, that the

irritability of the constitution and the rarefaction of the blood are so much increased by the warmth of the weather, that the frequency and severity of the fits are greater in the warm and sultry, than in the cold seasons of the year. In this case the humoral asthma is continued on during the summer months by the convulsive asthma, as a symptom of the natural and critical solution of the fits. After the convulsive asthmas there is often a great soreness in the breast, partly from the violent muscular exertion, and partly from the frequency and severity of the cough. Sometimes, too, there are shooting pains in the sides, which are extremely painful and alarming to the patient; but the judicious practitioner will easily distinguish them from internal affections of the breast, by the external soreness, and the acuteness of the pain in consequence of motion. The frequent returns of fits sometimes cause obstructions in the lungs, which, as the dissection of dead bodies clearly ascertains, appear full of knots or tubercles. These tubercles are most liable to occur in those who have naturally a narrow contracted chest, in which the lungs have not a free and easy motion; these render the disorder very obstinate, occasioning a long continuance of the cough after the asthmatic fit, frequently ending in small inflammations of the lungs, attended with internal pains, difficulty of breathing, and hectic fever. We have already observed, that the humoral asthma often supervenes on the convulsive. It is necessary also to observe, that the convulsive sometimes attacks those who have long been previously afflicted with the humoral asthma. Patients subject to catarrhs and winter coughs, during which they expectorate a considerable quantity of thick or frothy phlegm, are sometimes suddenly seized with violent difficulty of breathing, and great tightness over the breast, so as to dread even instant suffocation. This new complaint, after having tormented them for some hours, or perhaps a day or two, also leaves them suddenly, and they look back with surprise at their happy deliverance from so formidable and unexpected an enemy. Their old habitual cough and asthma, with soreness and stuffing in the breast, still remain; but they bear it without repining. In this manner they continue for some time, till the convulsive asthma returns, perhaps, with additional violence. Thus, the convulsive asthma becomes habitual to the patient, and he has the misfortune to find himself labouring under a complication of two diseases; the one aggravating the other, and both growing worse.

The convulsive asthma sometimes attacks persons of a thin spare habit, whose constitutions have been greatly emaciated by a long exposure to causes of general or chronic weakness. In some cases it seizes patients who are robust and full of blood, particularly if they have small vessels and strait chests. At other times it occurs in those who are gross, phlegmatic, corpulent, and in such habits it is often very distressing. In general, the indolent and luxurious suffer in a very considerable degree, and the disease seems to be conveyed to the children. It is frequently connected likewise with hysterical and hypochondriacal complaints, in irritable and relaxed constitutions. The convulsive asthma, recurring for many years, is capable of reducing the strongest constitutions, and of bringing on the symptoms of general debility; but if it attacks a

constitution already weakened and exhausted, it is obvious that it will necessarily weaken and exhaust it more. The stomach and bowels are more particularly liable to be affected in the convulsive asthma; they are often seized with colic pains, distended with wind, tormented with burning heats, and agitated with tremulous motions, which give a sensation to the patient of something moving and fluttering within him. Floyer, too, has observed, that slight fits of the asthma often affect the stomach and bowels, not the lungs. The appetite is greatly impaired, sleep is often prevented, or it is disturbed and unrefreshing. The menses are sometimes obstructed, and sometimes they are brought on before the usual period; and when plethora prevails, that discharge is accompanied with relief. The patient is generally costive, though sometimes he will have loose stools. The extremities, particularly the arms, shoulders, and upper parts of the body, are often affected with great uneasiness. Symptoms of fever are not essential to the disease, though they frequently occur, especially when the humoral asthma or a catarrh is complicated with the convulsive. A hectic fever, with a colliquative diarrhoea, faintings, palpitations, violent vomitings, coldness of the extremities, swelled legs, and other dropsical symptoms, arising from weakness, relaxation, and obstruction to the circulation of the blood through the lungs, is common in the last stage of the disease. Asthma may attack at any age, but its general approach is after the prime of life.

From the preceding account of the symptoms of the convulsive asthma, it will appear obvious that the *distinction* of it from every other disease cannot be difficult. The sudden attack of the fits, the short time of their duration, the violence of their symptoms, the state of ease and good health between them and their returning at intervals, will sufficiently characterise the complaint. The convulsive asthma is sometimes combined with the humoral asthma, pleurisy, peripneumony, dropsy of the breast, catarrhal and consumptive disorders; but the distinctions will require an accurate study of the respective histories of the different complaints which bear any resemblance to it. In many instances in the practice of medicine, words can never convey those minute distinctions which are very obvious to the eye and other senses.

When this disorder is recent, and produced by a decided occasional cause, there may be hopes of a lasting recovery; otherwise it is rarely, if ever, cured. An eruption of the menses, or of the hæmorrhoids, during a paroxysm, alleviates it; improper management causes an asthma more readily to end in a dropsy; paroxysms of convulsive asthmas greatly endanger the life at every return, yet seldom prove fatal. If frequent and long continued, should the patient escape with his life, a dropsy is the result, which is his destruction. If a slow fever comes on, an unequal intermittent pulse, a palsy of the arms, a continual palpitation of the heart, a preternatural small discharge by urine, or a syncope, death is at hand; as these symptoms show, that the heart or its connected vessels are organically injured. An asthma affecting old people usually attends them to the grave.

Dr. Cullen observes, "That the asthma depends upon a particular constitution of the lungs: that the *proximate cause* is a preternatural, and, in some measure, a spasmodic constriction of the muscular fibres of the bronchiæ, which not only prevents the dilatation of the

bronchiæ necessary to a free and full inspiration, but gives also a rigidity, which prevents a full and free expiration. This preternatural constriction," he adds, "like many other spasmodic and convulsive affections, is readily excited by a turgescence of the blood, and other causes of any unusual fulness and distention of the vessels of the lungs."

When this spasm is removed, the patient, after the expectoration of a little phlegm, feels himself almost restored to perfect health; for the cause being obviated, and there being no fixed obstruction in the lungs, the symptoms totally disappear. The proximate cause of the convulsive asthma, when complicated with the humoral, is a *spasmodic contraction* of the air vessels of the lungs, occasioned by an increased secretion of mucus, from a relaxation of the mucous glands.

The CHIEF PREDISPOSING CAUSES of the convulsive asthma are, a narrow contracted chest, morbid irritability of the lungs, and pulmonary obstructions in consequence of tubercles, either scrofulous or formed by repeated catarrhs, winter coughs, pleurisies, and peripneumonies.

The OCCASIONAL CAUSES of the convulsive asthma are, cold, moisture, sudden changes of weather, dust, metallic fumes, smoke and other particular smells, mephitic vapours, evacuations, great fatigue, neglect of exercise, shouting, and all strong exertions of the voice, certain disorders in the constitution, anger, joy, surprise, fear, grief, and other depressing passions, excess in venery, and intemperance in diet.

When, however, we compare the action of these remote causes with the spasm supposed to occasion the disease, the connection is not very clear; and, indeed, while anatomy has not ascertained the existence of muscular fibres in the bronchial cells, or the branches of the trachea ultimately terminating in them, it is not easy to admit this cause. There are, indeed, some reasons for supposing the diaphragm alone affected, since respiration is chiefly carried on by its means, and the convulsive asthma is intimately connected with the state of the stomach and bowels. When the diaphragm is affected, by consent of parts usually acting together, the intercostal muscles are also spasmodically contracted. This idea is in some degree supported by the symptoms of pleurisy, where the diaphragm gives little assistance in respiration, as the ribs cannot be raised without pain.

It cannot have escaped the attentive observer, that the remote causes and threatening symptoms of convulsive asthma and gout, are not very dissimilar; the period of attack, the firm health in the intervals, and the subjects most liable to these diseases, are still stronger marks of the connection; but our pathology is in too imperfect a state to explain the reason why a previous debility of the system, followed by irregular action, should, in one case, produce inflammation in the extremities; and in the other, spasm on the organs of respiration. We indeed see, in general, that those subject to asthma have some imperfect conformation of the chest, or some obstruction in the organs which it contains; and we see, also, that an accumulation of mucus in the bronchial glands, or a suppression of the usual discharge, will often bring on fits of true convulsive asthma.

A late author, Dr. Bree, who is himself an asthmatic, has endeavoured to bring us back to the humoral pa-

thology, and to connect more intimately the convulsive and humoral asthma, though not with signal success. His chief argument consists in the appearances after death: but we have already remarked, that these are effects only; and in general the quantity discharged at the termination of a fit is so inconsiderable, the relief is so often obtained previous to the discharge, and the marks of accumulation even when present are so trifling, that this opinion cannot be supported.

The hopes of relief are to be estimated from the violence and duration of the symptoms, the age of the patient, the condition of his constitution, the nature of the predisposition, and the power of the exciting causes. If the symptoms of the spasmodic affection in the lungs run high; if the disorder be of long standing, and, when once excited, continues for several days; if the returns of it be frequent; if the lungs be greatly obstructed with phlegm at the termination of the convulsive fits, and an obstinate cough remains during the intervals, with a laborious respiration, and a copious expectoration of mucous matter; the cure is difficult, tedious, and uncertain. Tubercles and obstruction in the lungs are symptoms too unfavourable to admit of hope. If, on the contrary, the disorder be recent; if the patient's constitution be not greatly impaired; if there be no natural deformity in the chest; if respiration after the termination of the fit be free, and the cough, with expectoration of phlegm, not violent nor obstinate in its duration; if the occupation of the person be not injurious to the lungs, or, if so, can be easily relinquished; and if the lungs be not obstructed with tubercles, either in consequence of a scrofulous habit, or repeated inflammatory affections, the case bears a favourable aspect, and may, in all human probability, be frequently treated with success. When infants are seized with the asthma, it often ends fatally, especially if powerful means for the removal of it be not applied at its commencement.

The CURE of ASTHMA must differ according to its nature, and the periods in which the remedies are employed. The only disease properly distinguished by this appellation is the convulsive asthma; but the humoral asthma is so often connected with it, at least as an exciting cause, that we shall consider it in this place.

The treatment of *convulsive asthma* must differ, when considered with a view of removing the fit, or of preventing its recurrence. It was formerly a constant practice, in every case of difficult breathing, to bleed; and bleeding has been repeatedly employed to mitigate the urgent symptoms of the morient. We have great reason to think that this practice has been highly injurious; and repeated bleedings in repeated fits have undoubtedly hastened the common termination of asthma, the dropsy. Yet so sudden is frequently the relief, that patients once accustomed to it are displeased if so ready a remedy is omitted, and it is often necessary to take a small quantity of blood to satisfy their minds: indeed it frequently happens that a slight bleeding will be equally useful with a large one. Such is the connection established in the human system by concomitant effects, that we are told by Dr. Whytt, that a nervous paroxysm has been removed by the momentary puncture of the arm.

Vomits are considered by Dr. Akenside as highly useful in shortening the paroxysm, and he recommends them to be given early, indeed almost in the moment of

the attack. We own that we have followed this practice with some hesitation, yet we have never found it inconvenient or dangerous. Physicians have usually waited till some expectation has come on, but the remedy is then unnecessary. Dr. Akenside gave very small doses of ipecacuanha only; and remarks, that it is equally useful when it nauseates, as when it vomits. The more rapid effects of the white vitriol have not, we believe, been tried, though they may probably unite a tonic power with the usual effects of vomiting.

Blisters require too long a period for their operation to be of great service during the fit; but, when the paroxysm is unusually protracted, they may be of service.

The chief benefit to be expected during the attack is from the volatile antispasmodics; and, as no inconvenience is likely to follow, expectorants have been combined with them. With the *mixtura camphorata*, have been united æther, aqua ammoniæ, tinctura fœtida, lac ammoniac, and even opium. The quickest and most diffusive stimulants are undoubtedly the best; and these mentioned may be combined in any proportion the physician may prefer. Opium is however a medicine of equivocal utility. It is mentioned because it has been recommended; but in our hands it has been rather injurious than useful. Mixing the opium with squills, or any active expectorant, or with gentle laxatives, to avoid its constipating effects, are proper precautions.

Bathing the feet in warm water has been sometimes useful; and in the very violent attacks, cataplasms, with garlic applied to the feet, have been of service. When a fit of true convulsive asthma is apparently connected with water in the chest, an active laxative has given great relief. In such cases, ten grains of jalap, with as much calomel, have been given with advantage.

The intervals between the fits are the periods when medicine may be most usefully employed; for though we lessen debility, and prevent in some degree any organic derangement by shortening and mitigating the fit, yet it scarcely ever happens that a paroxysm proves fatal.

The diet should, in general, be light and digestible; and every thing acedent and flatulent should be avoided. As life advances it should be more generous; and Madeira, or Port, if it does not produce acidity, may be taken with freedom, regulated by former habits. The less perfectly fermented ale is injurious, but porter is an excellent liquor with the meals; and, if not too flatulent or too strong, agrees well with asthmatics. In some cases of asthma however these liquors are too stimulant; and water, or a solution of cream of tartar in water, is found more useful. Though acedents are injurious, the acids less susceptible of further change, as vinegar, or the pure acid of tartar, are supposed to be very beneficial. Tea should be avoided; but coffee is supposed to be highly useful: and the warmer plants of our own country, as peppermint, rosemary, and pennyroyal, may with advantage supersede those of foreign growth. Supper should always be light of digestion, and not flatulent or acedent. The ship biscuits, with porter, or brandy and water not sweetened, or some beef tea, will fully supply this meal.

The situation of asthmatic patients is of great importance. In general, they cannot breathe with ease in an elevated spot; and too great a proportion of oxygen in the air, irritates their weak and susceptible lungs. In what the lower quality of the air consistent with their

case, consists, we know not. It has been suspected to be azote or hydrogen; but, from a fact mentioned by Dr. Percival, that the asthmatics who have been disordered by the fumes of lead, find relief from working in the lime kilns, it may be fixed air, which, from its greater specific gravity, falls into the lower strata of the atmosphere. Whatever may be the cause, the fact is well established. Asthmatics do not always find great advantage from a warmer climate. Such however is the variable nature of this disease, that some cannot breathe but in a less inclement atmosphere than this country affords.

The other physical qualities of the air are probably of importance. A due degree of elasticity is apparently necessary; but this, too, may be in excess, and produce inconvenience. An easterly wind is always injurious; but to what all the disadvantages of this peculiar state of the air may be attributed, we are yet ignorant.

The exercise should be steady and regular. Walking, for the reasons formerly assigned, is the most salutary; and sailing, for a similar reason, has been found very advantageous. If exercise on horseback or in a carriage is necessary, the feet must be well covered to keep up an equable, steady perspiration. Moisture should be carefully avoided; and, if accidentally wetted, the clothes should be immediately changed. The cold damp air of the night should be shunned with equal anxiety. Flannel should be usually worn next the skin in winter, and a moderately thick calico in summer.

Vomits frequently repeated have been found of considerable utility, and their advantages have been variously explained. Those who consider the source of the disease to be in the stomach, think the frequent evacuation useful; while others consider them chiefly as expectorants, or as determining very powerfully to the skin. All, however, confess their utility, and we have known them given every other morning for a considerable length of time, without appearing in the slightest degree to injure the stomach: on the contrary, they seemed to restore its action. The emetic has generally in these cases been assisted by mustard whey, and sometimes by the volatile alkali added to camomile tea, and occasionally by the infusion of the seeds *carduus benedictus*.

The steady action of the warmer purgatives is also of great importance in this disease. The connection of asthmatic paroxysms with flatulence and costiveness has been already pointed out; and obviating these has greatly contributed to extend the intervals of ease. The rhubarb and aloes appear to be the most useful; nor have we found any distinction in their merits, except that the former seems more applicable when the skin is dark and yellow, indicating an affection of the liver; and the latter, when these appearances are absent. Those subject to piles find aloes inconvenient; but in asthma, hæmorrhoidal inflammations are said to be advantageous. We know no subject in medicine less understood than the nature of hæmorrhoids, and their connection with the general health; nor can we promise to elucidate, though we shall notice, the more important facts relative to it. In the case before us, if the asthmatic feels advantage from these swellings, or the discharges of blood which sometimes accompany them, such is the distressing nature of this complaint, that he may assist both by aloetic purgatives; yet so painful and disagreeable is the disease, that in scarcely any other,

apoplexy and palsy perhaps excepted, would the change be considered as advantageous. Some authors have preferred the saline and the acid purgatives. In the earlier and more robust periods of life they may perhaps be more useful; but asthma is seldom the disease of youth and activity. The predisposition is, however, in some constitutions, so strong, that we have known its attacks commence so early as sixteen years of age.

There is another circumstance which renders the more cooling purgatives sometimes proper, which is the alternation of mania with asthma. We have seen some cases of this kind, and suspect that they are more common than authors have supposed; and in these, unless the maniacal affection be of the melancholy kind, salts and acid purgatives are better adapted to the complaint.

A remedy of peculiar importance is said to be a perpetual blister, or an issue; and we think that we have found a perpetual blister on the back, or on the breast, highly useful in preventing the return of fits. Of issues we have less experience; nor can we confirm by our observation the remark, that this discharge is as useful from the arm or thigh, as from parts nearer the chest. In affections of the chest, it has not been uncommon to employ blisters on the thighs and legs; or, in the more chronic complaints of these organs, issues. This remaining scion of the old doctrine of revulsion is now decaying, yet the practice has been very lately recommended by physicians of eminence; and, with all our theoretical prejudices alive, we cannot help adding, that we have seen these applications apparently useful.

Diuretics have been sometimes recommended; but as the principal remedy of this kind is the squill, it may be of service as an expectorant. If the nitre and sal ammoniac be ever useful, they must chiefly act by preventing the accumulations of those salts, which, previous to a paroxysm, appear to be retained by the urine becoming colourless.

Expectorants might be supposed a very useful class of medicines; yet, if the view we have taken of the disease be correct, we shall find it not occasioned by any accumulation of mucus, and we shall soon perceive on what foundation they have been advantageous.

The great object, in the interval, is to restore the tone of the system, and to support it. With occasional vomits, the steady and continued use of eceoprotics, sea bathing has been found highly useful, and it is strongly recommended by Dr. Ryan. The bark has been found of equal service; and, with the same view, Dr. Withers has recommended the flowers of zinc; and other authors, a mild alterative course of mercurials. Perhaps all the metallic tonics will be found useful, except perhaps the iron, which seems to combine too great a share of inflammatory stimulus. This idea may appear probably too hypothetical, and it is hinted only to suggest a little caution in its use.

These are the principal remedies of convulsive asthma; and we shall next consider the HUMORAL ASTHMA, as the accumulation in the bronchial glands acts often as an exciting cause of a convulsive fit, and in the old asthmatic, they are often united. The symptoms are the usual ones of a laborious and oppressive breathing, but accompanied with a wheezing noise in the respiration, which indicates an accumulation of mucus in the bronchiæ. The fit also, instead of lasting a few hours, is kept up many days, and at length terminates imper-

fectly, leaving the patient for a long time weak and languid; and, after various attacks, usually occasioning hydrothorax.

In this form of the disease the sputum is at first frothy, or of a gluey consistence, admitting of being drawn out in threads; and little or no relief is obtained till it is expectorated in rounder masses, is of a yellowish white, less tenacious, and more soft. Bleeding is here also employed to relieve symptoms, as suffocation is more frequent than in the true asthma, yet its repetition soon produces all the bad effects attributed to it in the convulsive species; and if the necessary quantity is at all exceeded, the weakness occasioned will render it difficult to bring on the proper expectoration. Vomits are more useful, and the squills given in such doses as to vomit or nauseate, produce the best effects. If there is much fever, they are assisted by antimonials, particularly the kermes mineral; if little or none, by the volatile alkali. In general, except in the very early stage, there is little fever; and the quickness and hardness of the pulse are the effects of the laborious breathing.

*Blisters* are in this complaint singularly useful, and there is no doubt of the propriety of applying them very near the back. They must often be repeated, and as soon as one has begun to discharge, another may be applied, as the stimulus of the cantharides appears to be chiefly useful. Cataplasms of garlic to the feet have been considered as very valuable assistants.

*Expectorants* are also of great importance, and the chief of these are the squill, the gum ammoniac, and the volatile alkali. Equal parts of the oily emulsion and lae ammoniac, to which is added as much of the tincture of squills as the stomach can bear, is a medicine of peculiar utility, and often will bring on expectoration in cases apparently desperate. The other expectorants are not of equal power; the inula will sometimes be useful when continued, and is adapted rather for the intervals than the urgent emergency of a paroxysm; and the asafetida, whose powers as a carminative and antispasmodic have eclipsed its numerous other virtues, merits considerable commendation in the same view. Even in the convulsive kind it becomes an excellent vehicle for the constant laxative. The olibanum, in many of its effects resembling the asafetida, is highly useful, and seems to combine a tonic with its expectorant power.

Respecting the propriety of purges in the humoral asthma, authors have differed. If given in any considerable dose, they induce debility, and retard the expectoration; but we have generally found, that to procure about two motions daily, has been highly salutary. These must, however, be produced by the mildest laxatives.

There are some cases where humoral asthma is combined with hydrothorax, or indeed where the latter puts on the appearances of the former. In these circumstances we have fortunately an active medicine, adapted to both diseases; viz. the squills. The distinction is, however, necessary, as the hydrothorax requires more active laxatives. In this disease, the hydropic diathesis is more conspicuous. The urine is scanty; the breathing, though oppressed, is not so violently obstructed as in asthma; the dyspnœa continues with less change; the lips are livid, and the

whole face more dark and swollen. The sleep is interrupted by sense of suffocation, and fainting recurs on the slightest motion. In such circumstances, diuretics and active laxatives are the only remedies.

Of the diuretics, the squill is the most powerful; but some of the more stimulating kinds are frequently useful; and great advantages are often obtained by the oil of juniper, or the oil of turpentine. These seem also to act as expectorants; and the balsam Peru, both as an expectorant, a stimulant, and a tonic, when the more violent urgent symptoms have disappeared, is an excellent medicine. In the intervals of this disease there is no room for the bark, as it is too astringent, except where the asthma is of the gouty kind. In other species, the cascarilla, the quassia, the cortex salicis latifoliae, the oak, or the argustura bark, may be given as a tonic. But, above all, it is necessary to keep up the determination to the surface, to avoid cold and damps of every kind, night air, and every cause of debility.

The asthma, in some instances, ends in a partial palsy; in others, in some species of dropsy; sometimes, though not often, the patient is suddenly suffocated. This accident, when it happens, hath for its cause a polypus in the lungs; and instances have occurred of its ending in an inflammation of those organs.

See Aretæus. Dr. Dover. Sir John Floyer on the Asthma. Cullen's First Lines, edit. iv. vol. iii. Withers on the Asthma. Dr. Ryan on the History and Cure of Asthma. Hoffmann on Convulsive Asthma. Bree on Disordered Respiration. Akenside in the London Medical Transactions, vol. i.

ASTHMA SPASMODICUM INFANTUM. The difficulty of breathing, which so often attacks during the period of infancy, is a disease of peculiar danger, and its different kinds are not easily discriminated. The suffocations from cold and teething are generally known by the fever attending, and the period of life, as well as the swelling of the gums. The difficulty of distinction chiefly lies between the spasmodic asthma, and cynanche stridula. The inconvenience has been greater, since, from the resemblance of the symptoms, remedies have been celebrated as successful in croup, which were never used in the disease; and the less experienced practitioner, trusting to them, has felt the severest disappointment. The distinction indeed is not easy, nor does it admit of explanation. The peculiar sound of the croupy breathing, which is known only from experience, decides the question. The sound of the asthmatic breathing is less shrill, and generally accompanied with some wheezing.

The remedies for the spasmodic asthma of children require the utmost activity in their administration. A blister must be immediately applied to the breast or back; an active emetic of tartarised antimony quickly given, in a dose that will secure its effects, and probably occasion also some discharge by stool. A warm bath will often prove advantageous; and the asafœtida, given with tinctura opii in a clyster, after some motions have been procured, either by the emetic tartar, an active clyster, or a dose of calomel, will relieve very effectually the spasm. To a child of two years old, two scruples of asafœtida may be given in a clyster, dissolved in two ounces of warm water, with thirty or forty drops of the tincture of opium; and this may be repeated in four or six hours, according to the exigency of the complaint.

VOL. I.

Dr. Millar, in the spasmodic asthma of children and the whooping cough, advises the asafœtida internally; and adds, that children are soon reconciled to the taste, and even grow fond of it. This may be true, but we have not been so fortunate as to meet with such admirers of the garlic flavour. Cataplasms of garlic, however, applied to the feet, have been often advantageous.

A'STITES GLANDULO'SI, (from *ad*, and *sto*, to stand near). A name of the prostate glands, because they are situated near the bladder. See PARASTATÆ.

ASTRA'GALO, ASTRAGALOIDES, (from *αστραγάλος*, and *ειδος*, likeness). See OROBUS.

ASTRA'GALUS, (from *αστραγάλος*, a cockal or die. So called because it is shaped like the die used in ancient games). ANKLE BONE. Also called the SLING BONE; *ballistæ os*; *aristrios*; *talus*; *quatrio*; *tetreros*; *cavicula*; *cavilla*; *diabebos*; *pieza*, or first bone of the foot.

It is the upper bone of the foot, the tibia rests upon it; its upper and under side are covered with cartilage, and on its under side it articulates with the os calcis; the fore part of this bone is cartilaginous, and there it articulates with the os scaphoides. Some apply the term to the vertebræ of the neck. Homer, in his Odyssey, uses it in this sense.

ASTRA'GALUS EXCAPUS, is a species of astragalus found in Hungary, said to be useful in syphilis. Two ounces of the dry root are boiled in three pints of water to a quart, which is to be taken daily.

ASTRA'GALUS. Also a name for the LIQUORICE VETCH. See OROBUS, and GLAUX VULGARIS LEGUMINOSA.

ASTRA'GALUS ACULEA'TUS, ASTRA'GALUS MASSILIE'NSIS, ASTRA'GALUS TRAGA'CANTIA ALBUS. See GUMMI TRAGACANTHA.

ASTRA'NTIA VULG. et NI'GER, (from *αστηρ*, a star, so called from the star-like shape of its flowers). See IMPERATORIA.

A'STRAPE, (from *αστραπια*, *corusco*). LIGHTNING. Galen reckons it among the remote causes of an epilepsy; and it is doubtless a cause of disease in lesser degrees of its influence, as well as of death in greater. In the Phil. Trans. art. xlii. ann. 1766, Dr. Laurence gives an instance of a singular effect of lightning.

ASTRI'CTA, (from *astringo*, to bind). When applied to the belly it signifies COSTIVENESS.

ASTRINGE'NTIA, ASTRICTO'RIA. ASTRINGENTS, (from *astringo*, to bind). ADSTRINGENTIA; called also *anastaltica*; *constringentia*.

The solid parts of the human machine, from various causes, are often so relaxed that they are unfit to perform properly their different functions. It seems necessary, therefore, that there should be such remedies as can correct debility, and bring back our solids to their former healthy state. Remedies of this sort among physicians are called ASTRINGENTS. That many substances have the power of condensing and strengthening the solid parts of animal bodies, is proved from that well known art of tanning and preparing leather by oak bark, and other similar bodies, until it acquires a remarkable hardness and firmness; chemistry has lately taught us that this change is produced by a principle called from its effects *taunin*, whose immediate action is to precipitate the gelatine. The application, however, of this principle to the human machine is not

E e

easy. Tannin cannot be introduced between every minute fibre of which the human body consists, nor could it precipitate the gelatine without its consequences being obvious, perhaps dangerous. We see no gelatine in the mass of blood; and the albumen, which does not greatly differ, forms that portion of the blood which is connected with the strength of the system; for in proportion to the density of the crassamentum, which is formed from the albumen, the strength is estimated. As the beneficial effects of astringents are first felt in the stomach, it is probable that the tannin acts on its fibres, with which those of the whole nervous and muscular systems seem to sympathize, unless we suppose that it produces such a chemical change on the chyle as to obtain a more dense and nutritious blood. In either way the change may perhaps be explained, and though not clearly and satisfactorily, yet as perfectly as many of the medical effects produced in our systems. The former of these ideas is not very different from the opinion of Dr. Cullen, who says, "That by the corrugation and constriction of the whole mouth and fauces, from a small portion of astringents being applied to a small part of the tongue, astringents act upon the sentient nerves; and that, taken into the stomach, they show their effects in other parts of the body so quickly, that they can hardly be supposed to have passed the stomach itself: therefore, their sudden effects in distant parts must be ascribed to an astringent power communicated from the stomach to those distant parts." The discovery of tannin is, however, of a later date, and its chemical effects seem to change the state of the question.

These considerations, however, assist us but little in explaining all the effects of astringents. While they render the simple solids more dense, they add also to the tone of the system, and give energy and activity to the vital. Muscular action is, at least, attended with increased density, and a stronger cohesion of the muscular fibres; and we can therefore perceive how astringents can increase *their* energy. But the tone of the nervous system is apparently connected with a fluid confined to the nervous fibrils; and the little we know of its nature shows no very striking connexion between increased density and increased nervous power. To avoid this difficulty, it has been supposed that astringents unite a tonic power; and, as we certainly possess tonics that are not astringent, so, on the contrary, some astringents may not be tonics, or the latter power may be combined without altering the sensible qualities of the former. The flowers of zinc and arsenic are certainly tonics without astringency; and catechu, the most powerful astringent, is not a tonic. It is not, therefore, improbable, that the two qualities may be combined; yet they are so often united in a body, that we are anxious to find a closer connexion. We may reflect, then, that though the astringents can have no effect on any fluid in the nerves, yet it seems probable that the state of this fluid, or power, differs according to the state of the simple solid, and to that of the nerves as such. In a warm climate, and from warm confined air, which relaxes the simple solid, the nervous energy is more mobile, but less strong. From cold, and in cold climates, the contrary takes place; and, in general, astringency and relaxation seem respectively to attend tone and irritability. Thus it happens that

astringents lessen irritability; and it is not improbable that the whole of their apparent tonic power is merely the diminution of irritability, by the condensation of the simple solid and the nervous system, so far as it is such.

Astringents are of very different kinds; or rather medicines of different powers produce their effects. Those which strictly deserve that title, make the impression of astringency or acerbity on the tongue, for the latter is the effect of astringency joined with acidity. To these only the explanations we have already entered into apply. The principle on which their power depends, we have said, is the tannin, in itself bitter, but probably uniting in the vegetable something which adds to its power. The property of striking a black with chalybeates, supposed to be the distinguishing quality of astringents, is now found to be characteristic of the gallic acid, which sometimes accompanies the tannin. The catechu, which we have styled the strongest astringent, produces no change of colour with vitriolated iron.

The natural orders, *stellatæ*, *senticosæ*, and *vaginales oleraceæ*, afford astringents of moderate power; and among the *cryptogamiæ* we may mention the *filix florida*, *trichomanes*, *equisetum*, and *muscus pyxidatus*. The ash, the *hæmatoxyllum campechianum* (logwood), the pomegranate, and the oak, are more powerful: and the *contortæ*, including the bark and the mahogany tree, perhaps equally so. The *acerb fruits*, particularly the sloes, are active astringents; but the inspissated juices, the acacia and catechu, from two species of mimosa, and the kino, are the most certain astringents of the vegetable kingdom. The dragon's blood has obtained its credit, from having been an ingredient in an active formula with other medicines of this class.

The mineral kingdom affords powerful astringents; but we do not certainly know on what principle this depends. Yet, as we find among minerals combinations not very different from those of the vegetable kingdom, we may conclude that a similar principle exists in them. This idea is strengthened, by finding that alum may, in many instances, be substituted with effect for some of the substances already enumerated. Vinegar and vitriolic acid possess an astringent power, and it is of course found in their salts: thus, the acetites of lead and copper, and the sulphates of clay and copper, are employed with singularly good effects.

*External* astringents are styled *styptics*, and we can more readily understand their action; but some of these act mechanically, as meal, lint, puff ball, and spider's webs. By inviscating the blood and assisting its coagulation, they form a thrombus, which fills the wound of the artery. The other external astringents are some of the substances already mentioned, particularly the earthy and metallic salts; but there is a third kind which act by coagulating the blood more directly: these are ardent spirits.

Astringents are employed externally, in hæmorrhages, in bruises, strains, and inflammations. In the three last the vessels are distended and weakened, and their effects are sufficiently obvious, but will be fully explained under the article INFLAMMATION, q. v.

Internally, they are used also for checking hæmorrhages, and immoderate evacuations of every kind; but the hæmorrhages to which they are adapted are the

passive, for when the action of the vessels is strong, and blood abounds, by lessening the area of the canals, they increase the disease. Their effect is probably produced by their action on the stomach, with which the extreme vessels sympathise; and as these are more irritable than the larger arteries, the astringent power is more conspicuous in them. In general, we have said that they lessen irritability; and they seem in many instances to correct acidity. From each effect they appear to be useful in calculous and nephritic cases. General debility is obviated rather by tonics than by astringents.

There is no great choice in the astringents employed. In moderate complaints it may not be necessary to use at once the strongest; and, in general, if we want a rapid change, sedatives and inirritants, particularly cold, nitre, and opium, are preferable to astringents, which always operate slowly. The acetite of lead is of an equivocal nature; but we have been unreasonably terrified on this subject, and if we interpose oily laxatives, it may be given with some continuance very safely.

Astringent vegetables yield their virtue to water, less perfectly to spirit. The astringency does not rise in distillation, nor is it dissolved by oils.

Medicines which imitate astringents in their effects have been arranged in this class. We have already alluded to sedatives and inirritants. The *solanaceæ* and the *rhæades*, including the fox glove and the poppies, have been for this reason accounted astringents. Abstinence and evacuations have been considered of the same kind.

Demulcents and antacids appear more decidedly astringent, by checking discharges from the bowels. The various boles, for ages commended and employed, may derive some virtue from the iron they contain, if iron be in reality an astringent. The argillaceous earth, of which they chiefly consist, acts as a demulcent in sheathing the abraded bowels. The gum arabic, as its parent plant, the mimosa nilotica, affords the acacia, may perhaps be supposed to possess a real astringency: it is, however, only a demulcent, and the calcined harts-horn is no more.

Chalk, oyster shells, and lime water, seem to act by absorbing redundant acids, which may prove a source of irritation; and, it is said, the earthly salts thus produced are astringent. Of this quality there is indeed no proof; and their combinations with the acetous acid are not found to be so, though of this kind is the acid which abounds in the stomach. If calcarous earth be so useful in leucorrhœa as some have supposed, it will show a degree of astringency at least in the combinations formed within the body. Strontian earth is an active absorbent, and has been, on this account, also recommended as an astringent. But of the virtues, or indeed the safety of this medicine, we know nothing.

See Fordyce. Gregory Conspectus Med. Wallis on Health and Disease. Cullen's Materia Medica.

ASTRIOLISM, (from ἀστὴρ, *a star*). BLASTING, or PLANET STRIKING.

A'STRIOS. See ASTRAGALUS.

ASTROBOLISMOS, A'STROBLES, (from ἀστρον, *a star*, and βάλλω, *to strike upon*; i. e. planet struck). The blasting of trees, or mortification by a blast; but when applied to the human body, it signifies an apo-

plexy or a splacculus. The first term is brought into our lexicons, but is used only by Theophrastus in his work on plants.

ASTROCYNOLÓGIA, (from ἀστρον, *a star*, κυνὴ, *a dog*, and λόγος, *a dissertation*). The name of a treatise on the dog days.

ASTRONOMÍA, ASTRONOMY, (from ἀστρον, *a star*, and νόμος, *law*). It is the science which teaches the knowledge of the heavenly bodies, showing their magnitudes, distances, order, and motion. Hippocrates says, that one ignorant of astronomy cannot be well qualified for a physician. Others, since his days, have greatly extolled the utility of this science in the study and practice of medicine; some styling anatomy the right eye of physic, and astronomy its left: for, they say, such is the influence of the sun, moon, and stars, especially the planets, upon terrestrial bodies, by the intervention of the ether and atmosphere, that they induce very sensible changes in them; but admitting some influence in the planets, it is in a degree too trifling to affect the practice of medicine. The planets may influence our atmosphere, and perhaps in some slight degree our bodies; but meteorology, and those branches of science by which we are taught the nature and properties of the air, seem more directly proper to medical enquiries.

It is pleaded, that the aspects of the stars influence the human body, because in the vernal equinox, or the summer solstice, the force of intermitting fevers is destroyed, though obstinate in all other seasons; and because that the equinoxes are peculiarly hurtful to some patients; but these circumstances are better accounted for on principles less remote than those derived from astronomy. The late Dr. Mead was a great advocate for this branch of science; and Dr. Balfour has more lately endeavoured to show the connection of the access or crisis of fevers with the solar and lunar conjunctions. This connection is not observable in these climates, but its existence cannot be wholly denied in the tropical regions.

A'STRUM, (from the Hebrew term, *acs*, *fire*). A STAR. With the chemists this word signifies that virtue and power which result from the preparation: thus the astrum of salt is its resolution into a fluid state, by which it can exert itself more powerfully. Astrum is a name given to many medicines.

A'SUAR. See MYROBALANI INDIA.

A'SUGAR. See ÆRUGO ÆRIS.

ASUOLI. See FULIGO.

A'TAC. See NITRUM.

ATA'XIA. ATAXY, (from α, priv. and τάσσω, *to order*). Some particular irregularity or disorder.

ATA'XMIR. An Arabic word expressing the method of treating an eye, when preternatural hairs grow under the natural ones.

ATE'CHNIA, ἀτεχνία, (from α, neg. and τεχνή, *an art*, *a want of art*). See ANAPHRODISIA.

A'TER SU'CCUS. See ATRA BILIS.

A'TERAMNIA, (from α, priv. and τείρω, *to break in pieces*). This word occurs in Hippocrates de Aëre, Locis, et Aquis, and is expounded by Galen as signifying difficulty of concoction, and hard. He observes, that the ancients gave this appellation to bad waters, and that, when joined with other words, it hath other significations.

ATHAMA'NTIA CRETE'NSIS. See DAUCUS CRETICUS.

ATHANA'SIA, (from  $\alpha$ , neg. and  $\theta\nu\nu\alpha\tau\omicron\varsigma$ , death). So called because its flowers do not wither easily. The IMMORTAL PLANT. A name given to TANSEY, because, when stuffed up the nose of a dead corpse, it is said to prevent putrefaction: see TANACETUM. It means also *immortality*. The name of an antidote of Galen, and another of Oribasius: it is the name also of a collyrium described by Ætius, and of many other compositions.

ATHA'NOR, ATHO'NOR, (from an Arabic word, *athan*). Among the chemists it is a sort of digesting furnace, contrived to maintain its heat a long time, communicating with its chimney by a lateral canal, as the furnace for a sand bath. It is carried to a considerable height above the part where this canal enters, filled with fuel to the top, and closely covered: as the lower part of the fuel consumes, it is supplied by what is above, which falls down into its place: thus a constant and equal heat is maintained a long time without any attendance. See FURNAX.

A'THENA. A plaster in much repute among the ancients.

ATHENATO'RIMUM. A thick glass cover, directed in the Theatrum Chemicum, vol. iii. p. 33, to be luted to a cucurbit, when the alembic is taken off in a particular process.

ATHENIO'NIS CATAPOTIUM. The name of a pill in Celsus's writings.

ATHENI'PPON. The name of a collyrium, also called *diasmyrnes*; and of many other collyria.

ATHENI'PPIUM. See ASCLEPIOS.

ATHE'RA, and A'THARA, (from  $\alpha\theta\eta\rho$ , corn). A sort of food made with wheat flour, like the pap-meal which is given to children. Pliny says it is an Egyptian invention.

ATHERO'MA, (from  $\alpha\theta\eta\rho\alpha$ , pulse, or *flap*). It is a kind of tumour, thus named from the consistence of its contents, and may be safely extirpated. See NÆVUS.

ATHLETICUS, ATHLETIC, (from  $\alpha\theta\lambda\epsilon\omega$ , to contend). A robust constitution fit for wrestling.

A'THRIX, (from  $\alpha$ , neg. and  $\theta\rho\iota\chi$ , hair). See ALOPECIA.

A'THROON, A'THROUS, (from  $\alpha\theta\rho\iota\zeta\omega$ , to collect). In medical authors it imports copious, accumulated, or sudden, and is the reverse of by degrees: similar to *confertus*.

ATHY'MIA, (from  $\alpha$ , neg. and  $\theta\upsilon\mu\omicron\varsigma$ , courage). PUSILLANIMITY. In medical authors it usually signifies that dejectedness, despondence, anxiety, and despair, which frequently occur in the course of distempers. In some authors it is synonymous with *melancholia*.

ATI'NCAR, or ATI'NKAR, (from *atin chama*, Arab.). See BORAX.

ATITA'RA. See PALMA MINOR.

A'TLAS, (from  $\alpha\tau\lambda\alpha\omega$ , to sustain, or  $\sigma\tau\lambda\eta\mu\iota$ , to carry). The name of the first vertebra of the neck; so called because it sustains the head, as Atlas was supposed to sustain the earth. It is a bony ring, and in its back part it receives the processus dentatus of the second vertebra; it hath no spinal process; its transverse processes are very thick; instead of the two superior oblique processes, which the other vertebræ have, there

are two oblong holes, which receive the condyles of the os occipitis, and the inferior oblique processes are horizontal to admit of rotation.

ATMOSPHE'RA, (from  $\alpha\tau\mu\omicron\varsigma$ , vapour, and  $\sigma\phi\epsilon\iota\rho\alpha$ , a circle). The ATMOSPHERE. See AER.

ATO'CHIA, (from  $\alpha$ , priv. and  $\tau\iota\chi\omega$ , flario). PRE-TERNATURAL LABOUR.

ATO'CIUM, (from the same, so called because some of the flowers bear no seed). See ANTIRRHINUM.

ATOLLI, (Indian). A sort of PAP, made of the meal of maize and water, which the Indians mix with their chocolate.

A'TOMUS, (from  $\alpha$ , neg. and  $\tau\epsilon\mu\omega$ , to cut or divide). An ATOM. It is a particle of matter exceedingly small; indeed the elementary particles of which bodies consist. Asclepiades taught that atoms were the primordia of all things, and that they were not perceptible to our senses, but only to our understandings; that they had no qualities, for the qualities of bodies which they compose, depend on the order, figure, and number, of many atoms joined together; and this last circumstance he proves by observing, that a lump of silver is white, but if filed down it is black; and horns of goats are black when whole, but white if filed down. Galen says, that Asclepiades, adhering to the sentiments of Democritus and Epicurus with regard to the principles of bodies, had only changed the former names of things, calling *atoms* molecules, and a vacuum, pores. Molecules were, however, divisible, but *atoms* not. This doctrine has been generally admitted as sufficiently probable, though incapable of demonstration, and with greater facility, as no important consequence is derived from it. Kant has, however, endeavoured to subvert it, by substituting what he calls the dynamic philosophy, changing the word *atoms* to *powers*, and real objects to their effects. Mr. Mitchell and Dr. Priestley, many years since, endeavoured to produce a similar change in the fundamental principles of philosophy, by transferring the sensation of resistance from matter, to a medium surrounding it, rather than to the ultimate atoms of the corpuscularian philosophers. Kant's system is very popular in Germany.

ATO'NIA, (from  $\alpha$ , neg. and  $\tau\epsilon\iota\omega$ , to stretch). ATONY; defect of muscular power. RELAXATION, or DEBILITY. This word was much in use among the methodic sect, who ascribed the causes of all distempers to relaxation, stricture, or a mixture of both. It is generally synonymous with palsy, and applied to every instance of debility, particularly in the muscular fibres.

ATOYA'XACOTL, ATOYA'XACOTL CHILTIC. See MACAXOCOTLIFERA.

A'TRA BILIS. *Ater succus; bilis atra*; BLACK BILE. According to the ancients it arises, 1st, From the grosser parts of the blood, and this they called the melancholy humour. 2dly, From yellow bile being highly concocted. Dr. Percival in his Essays suggests, that it is the gall rendered acrid by stagnation in the gall bladder, and viscid by the absorption of its fluid parts. *Bile* in this state discharged into the duodenum, occasions universal disturbance until it is evacuated; violent vomiting, or purging, or both; and previously the pulse is quick, the head aches, a delirium, a hiccough, intense thirst, inward heat, and a fetid breath, come on. Some describe this kind of bile as being acid, harsh, corroding, and, when poured on the

ground, bubbling up like a ferment. Dr. Percival says, that, by the use of the infus. sennæ limoniatum warmed with the tinctura columbæ, he has checked the vomitings occasioned by this matter. In many instances this bile resembles blood, and has been considered as such. The distinction is easy when the matter is diluted, as the blood has a reddish, and the bile a yellowish hue. See MELÆMA and MORBUS NIGER.

ATRACHE'LUS, (from α, neg. and τραχηλός, the neck). SHORT NECKED.

ATRA'CTYLIS, called *cnicus*, *carduus luteus*, *carduocnicus*, DISTAFF THISTLE, (from ατρακτος, a spindle).

It is a plant which grows in Italy, Greece, and other warm countries. Its leaves are of the same nature as those of the *carduus benedictus*, but the stalk is the part that is chiefly used. The women keep them for distaffs.

ATRAGE'NE, *flamula Jovis*, *clematis recta* Lin. Sp. Pl. 767, and TRAVELLER'S JOY. The whole plant is of a caustic quality, and laid on the skin quickly raises a blister. It has been used as a diuretic; and the infusion or extract has been given in the worst states of syphilis. Externally it has been applied to syphilitic sores and cancers. The infusion has been used in the form of a lotion. From two to three drachms of the dried leaves are infused in a pint of water; and of the extract of the leaves, from one to three grains are a dose. Some species of the *clematis* have been separated under this generic name, but it contains none of the medicinal kinds. Dale.

ATRA'MENTUM SUTO'RIMUM. A name of the GREEN VITRIOL, and *melantoria*. See VITRIOLUM VIRIDE.

ATRAPHA'XIS, or ATRAPHRA'XIS, (from παρὰ το ἀβρῶως ἀρξείν; so called from its quick growth). See ATRI'PLEX.

ATRE'SIA, (from α, neg. and τραω, or τρεω, to perforate). IMPERFORATION. See ATRETI.

ATRETA'RUM ISCHU'RIA, (from α, non, and τραω, to perforate). A SUPPRESSION OF URINE, from the menses being retained in the vagina. See ISCHURIA VESICALIS.

ATRE'TI, IMPERFORATE, (from α, priv. and τρητός, to perforate). Those of either sex are thus called, when their anus, or any other natural aperture, is closed.

A'TRICES, (from α, non, and ἄριξ, hair). Small tubercles near the anus, about which hairs will not grow; and which recede and return, especially at the first. Valesius de Taranta reckoned them among condylomata et fici.

A'TRICI. Small sinuses in the intestinum rectum, which do not reach so far as to perforate into its cavity.

ATRI'PLEX. The Greek term is ATRAPHAXIS, from whence some say the word is derived; q. v. O'RACH, or O'RACHE; also called *atriplex alba* or *rubra hortensis*, *arrache*, *atraphraxis*, *chrysolachanon*; WHITE, RED, or GARDEN ORACH.

It is an annual plant rising from seeds, and chiefly employed in the kitchen.

ATRI'PLEX FÆ'TIDA. Called also *garosmum*, *andraphex*, *vulvaria*, *chenopodium fetidum*, *chenopodium vulvarium*, *atriplex olida*, *blitum fetidum*; STINKING ORACH: is the *chenopodium vulvaria* Lin. Sp. Pl. 321.

It hath a strong disagreeable smell, somewhat like that of salt fish. That found growing amongst old

rubbish is weaker than that in moister ground. Water takes up all its virtue by infusion; but it loses its strength by keeping. It is a fetid anti-hysterical, antispasmodic, and acts without irritation. It can only be used in its recent state, as when dry it loses its sensible qualities. Therefore the best form is a conserve, of which two or three drachms may be taken in a day. Dr. Cullen wishes it was more often employed, Mat. Med.

ATRI'PLEX. MARI'TIMA, and PORTULA'CA. See HALIMUS.

ATRI'PLEX ODO'RA SUAVE'OLENS. See BOTRYS.

ATRI'PLEX SYLVE'STRIS, WILD ORACH. See CHENOPodium, AMBROSIOIDES, and RUBRUM.

A'TROPA, BELLADONA, (from Ἀτροπος, the goddess of destiny). See SOLANUM LETHALE.

A'TROPA MANDRAGORA. See MANDRAGORA.

ATROPHI'A, (from α, and τρεφω, to nourish). *Contubescencia*; *inutritio*; *marasmus*; *ariditas corporis*; an ATROPHY. It is a wasting, with loss of strength; but without hectic fever. Dr. Cullen remarks, that an atrophy perhaps is never without fever, at least the pulse is quicker than usual; but the absence of the *true hectic fever* distinguishes this disease from the *tabes*. It is also called a nervous consumption. Dr. Cullen places atrophy in the class CACHEXIÆ, and order MARCORES. He enumerates four species.

1. ATROPHIA INANITORUM, from too great evacuations; *tabes nutricum*, *sudatoria*, and a *sanguifluxu*.

2. ATROPHIA FAMELICORUM, from deficient nourishment.

3. ATROPHIA CACOCYMIKA, from bad nourishment, depraved digestion, or acrimony: *tabes syphilitica*, and *ab hydrope*.

4. ATROPHIA DEBILIUM, where the powers of digestion are weakened or destroyed. The atrophy of children is called *paedotrophia*, and the *tabes dorsalis* belongs to the fourth species.

An atrophy, from whatever it may proceed, arises from a defective exertion of the assimilating powers of the constitution, an impediment to the application of the nourishment obtained; by which even the functions of the machine, ordained for the support, becomes its destruction; or from a preternatural discharge of the healthy fluids: acrimony, requiring excessive absorption for its attenuation or sheathing, is scarcely an object of the present article, as it is most commonly connected with hectic fever.

The signs in the beginning are, a decrease of strength, loss of appetite without fever, cough, or short breath, though in the progress, when atrophy has induced great weakness, there is some degree of difficulty in the breathing; the urine is inconstant in its colour, though generally high, and small in quantity; sometimes it is pale and profuse; in time the blood seems to grow hot and acrid for want of its due supplies, a febrile heat increases, as well as a cough, and difficulty of breathing. In children this disease frequently happens; and, besides the above mentioned causes, they are subject to it from a sudden change from the breast to more solid food; in which case their legs become pendulous, the habit flaccid, their skin corrugated, and, in many instances, their appetite for food is almost insatiable. As a weakness in their chylopoietic organs

is the cause, so, on dissecting those patients after death, their mesenteric glands are tumefied, their livers much disordered, their intestines filled with black fetid sordes, and the muscles of their bellies extenuated almost to a membrane. It is, however, doubtful whether this disease is not rather referable to scrofula. See TABES MESENTERICA.

Atrophy should be distinguished from leanness, the rickets, and that weakness and leanness in some children, who pine only for want of a due supply from the breast.

The cure will be regulated by the cause.

If this disorder depends on any other, as on a diarrhœa, fluor albus, diabetes, gonorrhœa, or hæmorrhages, the relief will depend on the cure of the original disease.

If the cause is indigestion, with a viscid obstruction of the mesentery, which is the case in children, and sometimes in old people, gentle occasional doses of rhubarb with calomel, or sal polychrest, and in the intervals, stomachics, with warm tonics, are useful. Irritating purges weaken the patient too much. Ferrugineous medicines, and the bark, contribute to the cure; though in this complaint the best plans often fail.

The scrofulous and cancerous cases only admit of palliation, by keeping the circulation as low as the general health will admit. A thin light diet is the most proper, such as jellies of vegetable and animal substances, and broths; supporting the strength by the bark, and dilute vitriolic acid.

When excessive evacuations have been the cause, the decoction of sarsaparilla, salep, chalybeate waters, bark, cold bathing, and gentle riding, are proper. A species is mentioned by authors, arising from a compression of the thoracic duct by a tumour; but this is evidently beyond the reach of medicine, as atrophy from a rupture of this duct would be.

A venereal taint is often an unsuspected cause; in which case mild mercurials, with sarsaparilla, and a milk diet, are the cure. See Sauvages' *Nosologia Methodica*. Hoffman, *Syst. Rat. Medicinæ*. Morton. Willis.

A'TTA, (from *αττω*, to *leapt*). Festus says, it is one who, by reason of the tenderness or other defect in his feet, touches the ground lightly rather than treads on it.

A'TTAGEN, ATTAGE'NA PHRYGIA. The name of an Asiatic partridge, so called from its skipping motion; it is commonly known by the name of FRANCOLIN. The Greeks call it *lagopus*, *hare's foot*, because its feet are downy. It is of a dusky red colour on its back, and seems to be the same as our *red cock*, which Aldrovandus calls *attagen*. Ray names it *francolino Italorum*; and in Gmelin's Linnæus, it is a variety of the *tetrao legopus*. Pliny describes it under the name of *lagopus altera*, and with us it is called the *red cock*, *gor cock*, *moor cock*, or *red game*. They are most highly flavoured in autumn, are not remarkable in medicine, though the gizzard, on its inside, is very fragrant just after the bird is killed.

ATTA'LICUS. The name of some compound medicine mentioned by Galen.

ATTENTION, is a voluntary, though sometimes an involuntary exertion of mind, either in expectation, or watching the progress of any successive events. At-

tention to sounds is regulated by the tension of the membrana tympani; and attention exerted in general, has sometimes obviated nervous paroxysms, or lessened the shock of a smart short pain, as from drawing a tooth. The attention required in some skilful games, as that of chess, has even drawn the mind from the thought of a speedy certain death.

ATTENUA'NTIA, (from *attenuo*, to *make thin*). ATTENUATING MEDICINES act, it is supposed, by diminishing the consistence of the blood, or secreted fluids, and almost exclusively of the fluids. Those which operate by immediate contact are few, and are water, or such as abound with water, as on this they depend for their action only. Yet water alone will not readily mix with the animal fluids, and it is often thrown out by the kidneys as an injurious substance, unless joined with farinacea or animal juices, so as to be submitted to the action of the stomach. Certainly, water is not alone an attenuant. It may be, however, doubted, whether the blood is in any instance too viscid; the buff coat in blood is owing to a very different state. If, however, the gluten is ever morbidly viscid, the neutral salts are the only proper attenuants, and soap as containing an alkali may be such. The sweet fruits and sugar also produce some effect in attenuating the blood. The obstructions from more solid substances can never be attenuated by any fluid; and the only successful mode of treatment is, to excite the action of the vessels. Mercury may perhaps have some effect, but its influence in attenuating the fluids arises wholly from its increasing the action of muscular fibres of the sanguiferous system. See Hoffman, vol. i. and ii. cap. iv. Cullen's *Mat. Med.*

ATTICUM. The name of a plaster used by Hippocrates. When applied to honey or wax it means Athenian: as those, in the neighbourhood of Hymettus, were the best.

ATTO'LLENS, (from *attollo*, to *lift up*). It is an epithet applied to some muscles, whose office it is to elevate the part to which they are attached.

ATTO'LLENS AURICULÆ SUP'RIOR MU'SCULUS. A muscle which rises from the corrugator supercilii by a thin fascia.

ATTO'LLENS OCULI, i. e. *Musculus superior*, et *rectus superior oculi*. See ELEVATOR OCULI.

ATTONITUS MO'RBUS, et STUPOR, (from *attonitus*, *surprised*, because the person attacked falls down suddenly). Names of the APOPLEXY, q. v. It is also given to that species of palsy which succeeds the apoplexy. See PARALYSIS.

ATTRA'CTIO, (from *attraho*, to *attract*). See REPULSIO and AFFINITAS.

ATTRACTIVUM, (from the same). ATTRACTIVE. Paracelsus pretends to have had an *attractive* medicine which would draw away the diseases of the body; but the extravagances of this whimsical genius with respect to it, though not deserving a place here, may be met with in his *Archidox.* lib. vii.

ATTRACTIVUS, (from the same). ATTRACTORIUS, and ATTRAHENS, are applied to remedies that have a power of attracting or drawing.

ATTRITA, ATTRITO, (from *attero*, to *rub together*). ATTRITION. See INTERTRIGO.

A'TYPOS, (from *α*, negative, and *τυπος*, a *form* or *tenor*). IRREGULAR. It is applied to diseases which

have no regularity in their periods; and to a deformity in the limbs.

**AUA'NTE, AU'APSE**, (from *auxiva*, to dry). The DRY DISEASE. The patient cannot bear either abstinence or eating. Fasting causes a rumbling in his belly, and gnawing pain in his stomach. He vomits up various matters, and after vomiting he is at ease. After eating, there are cructations; an inflammatory heat and redness; a constant feeling as if a painful stool was to be discharged, yet only wind is evacuated; a head-ach; a sense of pricking, as with needles, in different parts of the body; the legs seem heavy, grow feeble and extenuated, and he becomes weak: (Hippocrates). It is not easy from this account to ascertain the real complaint, unless it be an accumulation of sordes in the stomach and bowels. In confirmation of this idea, he prescribed at first a purge, and after it an emetic; he then directs abstinence from fat food, temperance, bathing, unctions, and moderate exercise.

**AU'CHMOS**, (from *ava*, to dry). The Latins call it *squalor*. It is hot, dry, sultry weather.

**AUCUPA'LIS or AUCUPA'RIA**, (from *aucupor*, to endeavour to catch,) so called because birds are taken by its berries. See **ORNUS**, and **SORBUS SYLVESTRIS**.

**AUDA'CIA**, (from *audax*, bold). In a medical sense it is that sort of boldness which we meet with in delirium or madness.

**AUDITO'RIA ARTERIA**, (from *audio*, to hear). The internal auditory artery goes off from each side of the *arteria basilaris* to the organ of hearing, and accompanies the auditory nerve, having first furnished several small twigs to the *membrana arachnoides*.

**AUDITO'RIOUS MEATUS**, (from the same). The passage that conveys the air to the auditory nerve. It leads from the lower anterior part of the concha to the tympanum, and is partly bony, partly cartilaginous; all within the temporal bone is the bony part, it is the longest, and forms the bottom; the rest is cartilaginous, and makes the external opening or orifice of the canal: these two parts make a canal of about three fourths of an inch long, a little tortuous, and wider in some parts than in others. On the membranous covering of the cartilaginous part we observe the yellow bodies, supposed to be the *glandulae ceruminis*. The bony part of the *meatus* is nearly horizontal and straight; the cartilaginous part only is curved and winding, which should be observed when a syringe is used to inject any thing with into the ear.

**AUDITO'RIOUS NERVUS**. The AUDITORY NERVE. The seventh pair of nerves are called *auditory nerves*; so are the *sympathetici minores*. This seventh pair of nerves run into the *os petrosum*, and are there divided into the *portio mollis*, which is spent upon the labyrinth of the ear, and distributed to the *meatus auditorius internus*, passing to the *vestibulum cochleæ*; and *portio dura*, which goes out by the aqueduct, between the mastoid and styloid processus, passes through the parotid, becomes a cutaneous nerve, and communicates with the upper maxillary. On these nerves, no covering from the *dura mater* can be traced.

**AUDI'TUS**, (from *audio*, to hear). The sense of HEARING, also called *acoë*. By this sense we perceive the elastic tremors of the air; and to facilitate the function, the organ of hearing is made up of hard bones,

and of elastic cartilages and membranes. The elastic air only receives sonorous tremors, and transfers them, as we see water transfer any impulse given to it. The sound is increased in air that is condensed, and is lost in a vessel emptied of its air. The body, which produces sound, ought to tremble or vibrate in the smallest of its particles. From such a tremor the contiguous air is beat into waves, whereby the parts of the air that lie outermost are compressed, and fly back again as soon as their elasticity conquers the impulse. The air consequently flies again towards the sonorous body, where it is now more loose and rarefied, to be again compressed by the impulsive power; and in the same manner the anterior and outer portion of air surrounding that which is impelled, is by the action of the latter compressed and removed further from the trembling body, yet so as to return again in its proper time by the force of elasticity, driving its contents to the tremulous body for the exciting a new wave. These impulses of the air are required to succeed each other with a certain velocity; and in order to render them audible, they must not be fewer than thirty in a second of time. As these sonorous waves are more frequent in a given time, so much sharper is the sound heard, and the more strongly does it affect us, till we come to the most acute of audible sounds, which have 7520 tremors in a second. Acute sounds are in general yielded from bodies that are hard, brittle, and violently shook or struck; but grave sounds from bodies of a contrary nature. Sounds, whether acute or grave, are carried through the air with a celerity equal to about 1038 Paris feet in a second; but a contrary wind retards their progress about one-twelfth of their velocity. Sounds, as arising from elastic tremors, are reflected from hard bodies in angles, equal to those of their incidence; but the same sound conveyed to the open air, and dilating through an immense sphere, grows proportionably weaker; but if it pass through a tube in a cylindrical shape, it is increased; therefore, the sonorous waves of the elastic air being driven into the cartilaginous funnel of the ear, are repelled and collected together by alternate reflections from its elastic sides into the cavity of the concha, from whence it proceeds through the auditory passage, with a force so much stronger as the surface of the outer ear is larger than the section of the auditory passage, through which the same force is continued entire forward, and increased by new reflections, excited from the percussion of the elastic cartilages and hard bones, so as to mix imperceptibly with the primitive sound. At the bottom of the auditory passage is the MEMBRANE OF THE DRUM OF THE EAR, called *MEMBRANA TYMPANI*; sometimes by the barbarous terms *myringa*, *myrinx*. It is a thin, transparent, flattish pellicle, the edge of which is round, and strongly fixed in the circular groove which divides the bony meatus of the external ear from the tympanum or barrel: this membrane consists of several plates, one of which is dry, rattling, splendid, and pellucid. It is very tense, easily put into a tremulous motion; and upon it the sonorous waves or modulations of external air strike, move the small bones fixed to it, and it proves a means of sound being readily conveyed to the common sensorium. This membrane is stretched over a cavity in the *os petrosum*, called the *TYMPANUM* or *DRUM*, which consists of several cavities. In the tympanum, which is of an irregular oblong figure, are

the bones of *hearing*, lodged in its hollow part, between the pars petrosa and squamosa of the temporal bones. The cavities of the tympanum are, the opening of the *mastoid cells*; that of the *Eustachian tube*, the *canalis semi petrosus*, *half bony canal*, the *fenestra ovalis*, and *rotunda*. Within the tympanum are suspended the bones of hearing moveably; the first of which is the *malleus*, or *hammer*, whose handle is fixed to the membrane of the drum; and at one end to the second bone, called the *incus*, or *anvil*, which it resembles in shape, to which it conveys the tremors impressed upon the membrane: the incus rests on the *os orbiculare*, a small round bone, and this upon the stapes or stirrup; the stapes and the air of the tympanum press the auditory nerve, whence the sense of sound is conveyed to the common sensory. When, by the force of external sounds, the membrane of the drum is forced too much inward, it is probably supported by air which passes from the mouth through the Eustachian tube into the inner ear. The importance of the cochlea of the ear, in order to the conveyance of the sound, is very considerable. For a more minute information, consult Haller's Physiology, and the ingenious observations of Dr. Shebbeare on this subject, in his Theory and Practice of Physic, and the article *Sonus*.

**AUGMENTUM**, (from *augeo*, to increase). **AUXESIS**, (from *αὐξανα*, to increase). The increase of a disease, from its attack to its height.

**AUGUSTA**. An epithet given to several compound medicines.

**AULISCOS**, (from *αυλος*, a pipe). See **CATHETERUS**, and **FISTULA**.

**AURA**, (from *αἴρ*, air, or rather from the Hebrew term *אור*,) signifies an exhalation, or vapour, which arises from mephitic caves. The chemists mean by it a certain fine and pure spirit, found in every animal and vegetable body; but so subtle as only to be perceptible to us by its smell.

**AURA EPILEPTICA**. A gradual sensation, like air ascending from some determined part of the extremities upwards, occasioning an epileptic attack. In the *Ephem. Nat. Cur.* An. 3. Obs. 336; and in a treatise of Galen on an epileptic boy, there are evident examples of an epilepsy *per consensum ab aurâ adscendente*.

**AURA VITALIS**. So Helmont calls the vital heat.

**AURANTIA**, (ab *aureo colore*, from its golden colour). **ENASCENTIA**, and **IMMATURA**. See **AURANTIA CURASSAVENTIA**.

**AURANTIA HISPALENSIS**, called also *mala aurantia fructu acido*, *major arantia malus*, *aurangia*, *mala aurea*, *chrysomelea*, *nerantia*, *martianum pomum*; *poma anarantia*; **SEVILLE ORANGE**. It is the *citrus aurantium* Lin. Sp. Pl. 1100.

The China and Seville orange are both only varieties of the same species: the latter is only found in our Pharmacopœias; and the *flowers*, *leaves*, *yellow rind*, and *juice*, are made use of for different medical purposes.

The **FLOWERS** of this tree are highly odoriferous, and are used as a perfume; they are bitter to the taste; they give their taste and smell both to water and to spirit, but most perfectly to rectified spirit of wine. The water which is distilled from these flowers is called *ol. naphæ*. In distillation they yield a small quantity

of essential oil, which is called *oleum vel essentia neroli*, they are brought from Italy and France.

The **LEAVES** have a bitterish taste, and yield by distillation an essential oil; indeed by rubbing them between the fingers and thumb they manifest considerable fragrance. Westarhoef, De Haen, and several German physicians, have spoken highly in favour both of the flowers and leaves, but particularly of the latter, and held them in great estimation as a remedy for epilepsy and other convulsive disorders; but from later experience they have sunk greatly in their reputation. The dose of the leaves in powder was from ʒ ss. to ʒ i. two or three times a day, and in decoction proportionably strong. They resemble the laurel and the bitter almond, and may owe their taste also to the prussic acid.

The **YELLOW RIND** of the fruit, freed from the white fungous part, is warmer than the peel of lemons, of a more durable flavour, and abounds more with a light fragrant essential oil, which exudes upon wounding it. Infused in boiling water it gives out nearly all its smell and taste; cold water extracts the bitter, but very little of the flavour. In distillation all the oil rises without the bitter. The yellow rind gives an agreeable flavour to the other medicines, and has deservedly gained the character of a pleasant warm aromatic bitter. Its expressed oil is *essence of bergamot*.

The orange peel is commonly employed as a stomachic, promotes appetite, and is particularly useful in restoring tone to the stomach when it has been impaired by excess. It has been also much celebrated in cure of intermittents, and in those of a most obstinate kind; and as a powerful remedy in menorrhagia, and immoderate uterine evacuations. It is, however, little more than a light bitter, not very powerful in any of these diseases. The London college direct a syrup and tincture. In the former, eight ounces of the peel are steeped in five pints of water; and in the latter, three ounces of the peel are digested in a quart of proof spirit.

The **JUICE OF SEVILLE ORANGES** is a grateful acid, which, by allaying heat, quenching thirst, promoting various excretions, and diminishing the action of the vascular sanguiferous system, proves extremely useful in both ardent and putrid fevers, though the China orange juice, as impregnated with a larger proportion of sugar, becomes more agreeable, and may be taken in larger quantity. The Seville orange juice is particularly serviceable as an antiscorbutic, and alone will prevent or cure scurvy in the most apparently desperate circumstances. In dyspepsia, putrid bile in the stomach, both lemon and orange juice are highly useful. The acid of the Seville orange differs in some of its pharmaceutical properties, both from the fermented acid of vinegar, and from the native acid salts of the leaves or plants: from the former in its not being volatile, or not exhaling upon inspissating the juice, nor rising in distillation with the heat of boiling water; from the latter, in its being soluble in spirit of wine: the inspissated juice liquifies in air, water, or spirit of wine; whence it is easily preserved during many years, either in the form of an extract, or in a spirituous solution.

**AURANTIA CURASSAVENTIA**. **AURENTIUM CURASSAVENSE**. **CURASSOA**, or **CURASSAO**, **APPLES**, or **ORANGES**. They seem to be the immature oranges that by some accident have been checked in their

growth. They are a grateful aromatic bitter, of a flavour very different from that of the peel from the ripe fruit, and without any acid; what little tartness they have when fresh is lost in drying. Spirit of wine extracts perfectly all their virtue; water imperfectly: infused in wine or brandy they afford a good bitter for the stomach. They are used to promote the discharge in issues, whence their name of *ISSUE PEAS*, and to give the flavour of hops to beer.

*AURANTIA SINENSIS*, called also *aurantia dulcis*, *poma Sinensia*, *mala aurantia Chinensia*, CHINA OR SWEET ORANGES.

The rind hath a faint smell, with but little bitterness, and is never used in medicine; the juice hath a grateful subacid sweetness, in general of the same qualities as our summer fruits.

*AURATUS GERMANORUM*, (from *aurum*, gold). It is an oleo-saccharum with the oil of cinnamon, called *AURUM HORIZONTALE*.

*AUREA ALEXANDRIA*. An antidote invented by Alexander.

*AURELIANA CANADENSIS IROQUÆIS*, (ab *aureo colore*, from its golden colour). See GENSING.

*AUREUS*, (from the same). A weight equal to a drachm and a half; also a pompous appellation for many compound medicines. Blancard says it was a weight amongst the Arabians of a drachm, a seventh part; the same with *denarius*.

*AURICHALUM*, a corruption of *ORICHALCUM*. See *Æs*.

*AURICOLLA*, (from *aurum*, gold, and *κόλληω*, to glue together). A substance with which goldsmiths solder gold. See *TINCAL*.

*AURICULA* (from *auris*, the ear). The EXTERNAL PART OF THE EAR; which is divided into the upper part called *pinna*, and the lower soft part called *lobus*, or *lobulus*. The pinna is divided into several eminences and cavities; the eminences are the *helix*, called also *capreolus*; *anti-helix*; *tragus*, called also *anti-lobium*; and *anti-tragus*.

The *helix* is the large border round the ear, or the exterior compass of the ear; so called because of its tortuosity.

The *anti-helix* is the large oblong eminence, surrounded by the helix.

The *tragus* is the like anterior protuberance, opposite to the lobe, below the fore part of the helix, which in the aged is often covered with hairs.

The *anti-tragus* is the posterior protuberance below the inferior extremity of the anti-helix. The name of a muscle which acts only upon the cartilage of the ear.

The cavities are the *scapha*, on the inside of the helix; the *cavitas innominata* or *fossa navicularis*, at the anterior upper part of the anti-helix; the *concha*, which is situated under the anti-helix, divided by a *septum*, which is a continuation of the helix; and the *meatus auditorius externus*.

The *auricula* is composed chiefly of cartilage, which gives and preserves its shape. It hath the advantage of being variable, for there are certain small muscles called *helicis major* and *minor*, *tragicus*, and *anti-tragicus*, which are peculiar to the ear; they act only upon the cartilage, and contribute to direct it towards

sound; or by giving a greater tension, to increase its intensity.

The external ear is fixed to the cranium, not only by the cartilaginous portion of the meatus, but also by the ligaments, viz. the anterior, which is fixed by one extremity to the root of the apophysis zygomatica of the os temporis, close to the corner of the glenoid cavity, and by the other extremity to the anterior and superior part of the cartilaginous meatus. The posterior ligament is fixed by one end to the root of the mastoid apophysis, and by the other to the posterior part of the convexity of the concha, so that it is opposite to the anterior ligament. There is also a kind of superior ligament which seems to be only a continuation of the aponeurosis of the frontal and occipital muscles.

The lobe seems to be a doubling of the teguments; it is only skin and cellular membrane. For a particular account of the vessels, &c. see *AURIS*.

*AURICULA INFIMA*. The LOBE OF THE EAR. Besides, it is the specific name of several herbs, from their supposed resemblance to ears.

*AURICULA LEPORIS*. See *BUPLEURUM*.

*AURICULA MURIS*. See *ALSINE*.

*AURICULA URSI*, called also *sanicula Alpina lutea*, YELLOW BEAR'S EARS, *oricola*, and FRENCH COWSLIPS. It grows plentifully in Switzerland, Savoy, and many other places; bears thick, large, green leaves; and on the tops of the stalks there are flowers of different colours. In Utrecht this flower is called *primula odorata*, on account of its agreeable smell. The juice removes spots on the face.

*AURICULÆ CO'RDIS*. Two muscular bags at the basis of the heart. See *COR*.

*AURICULÆ JU'VÆ*, called also *fungus sambuci*, *fungus membranaceus*, *peziza auriculam referens*, *agaricus auriculæ forma*; JEWS' EARS. *Peziza auricula* Lin. It is a sort of fungus, which grows on elder trees; its internal use is generally thought not safe, but a decoction in milk has been a much esteemed gargle in the quinsy.

*AURICULARIA*, (from *auricula*, the ear). See *MENTHA PALUSTRIS FOLIO OBLONGO*.

*AURICULARIS*. See *EXTENSOR MINIMI DIGITI*.

*AURICULARIS DIGITUS*. The little finger is called the ear finger, because with it we are most apt to rub and pick the inner ear.

*AURICULARIS MEDICUS*. A physician for the ear.

*AURICULARIUS*. Belonging to the ear, also an ear doctor.

*AURICULARUM SEPTUM*. See *COR*.

*AURICULATUM*, vel *AURITUM FOLIUM*, an EARED LEAF, from *auricula*, a little ear; twisted into the form of a little ear, or having an appendage like a little ear: or they are heart shaped, but have the corners prominent and rounded, but with an additional smaller lobe near the base.

*AURIGA*. A WAGONER. A sort of bandage for the sides, described by Galen. So called because it is made like the traces of a wagon-horse. It was also a name given by the ancients to a lobe of the liver. They divided the liver into four lobes; the *first* was called *focus*, from a ridiculous belief that there the food was concocted; *second*. *MENSA*, because they thought the

aliments of the limbs were placed there; the *third* CULTER; and *fourth* AURIGA, as conducive to the distribution of the aliments.

AURI'GO, (ab *aureo colore*, from its *yellow colour*). See IC'TERUS.

AURIPIGME'NTUM, (from *aurum*, *gold*, and *pigmentum*, *paint*,) also called *arsenicum croceum*, *arsenicum flavum*, *adarnech*, *albimec althanaca*, *ethel*; ORPIN, ORPIMENT, and AURIPIGMENT. Galen called it *arsenicum*, and Serapion *narueh*.

There are three kinds of orpiment; the gold coloured; the deep red mixed with yellow, called *andarac*, *auripigmentum rubrum*; and the greenish and yellowish, which is the least valuable. The best is a yellow shining sulphureous mineral, consisting of little flakes or scales like talc. If powdered orpiment is set on fire, it will flame, and yield the odour of common brimstone; if a plate of copper is held over these fumes at their first rising, it becomes white and brittle; an iron plate is also turned white by them; and it is soluble in oil. But, as is the case with crude antimony, its sulphureous combination is such as to render the arsenic inert. If it is kept long in a subliming vessel over the fire, the whole mass is raised, and concretes in the upper part of the vessel into a red pellucid substance like a ruby, leaving only a very small portion of metallic earth at the bottom.

Some use it for fumigating venereal ulcers; Drs. Boerhaave, Mead, and others, commend its fumes in asthmas; mixed with quick lime it hath been used as a depilatory. The painters use it for a gold colour, without the idea of its being poisonous; but if swallowed, its effects are similar to those of the hydrargyrus muriatus.

AURIPIGME'NTUM RU'BRUM. See REALGAR.

AU'RIS, (from *aura*, *air*, as being the medium of hearing). The EAR. The *ear* is usually divided into the external and the internal. By the external is meant all that lies without the external orifice of the meatus auditorius in the os temporis; see AURICULA. By the internal, all that lies within the cavity of this bone; the orifice of which is called *cyar*. For MEATUS AUDITORIIUS, TYMPANUM, and LABYRINTH, see LABYRINTHUS, &c.

The arteries of the external *ear* come anteriorly from the arteria temporalis, and posteriorly from the occipitalis. The veins are branches of the external jugulars. The portio dura of the auditory nerve having passed out of the cranium through the foramen stylo-mastoidæum, gives off a branch, which runs up behind the ear, whence it sends off several filaments to the meatus and fore side of the ear. The second vertebral pair send also a branch to the *ear*, the ramifications of which communicate with those of the other branch from the portio dura.

The bones of hearing, called *malleus*, *incus*, *orbicular*, and *stapes*, are placed in the cavity of the tympanum, immediately on the inside of the membrana tympani. The malleus is joined by its handle to the membrana tympani, and its round head rests on the incus, the long leg of which rests on the os orbiculare, which is fixed to the fore part of the stapes, the sole of which rests on the hole called fenestra ovalis.

The use of the external *ear* is to collect sounds, and

to render their impression on the other organs of hearing most perfect; this is evident from those who have their ears cut off being obliged to use a horn, or some means to assist them in hearing: all animals, as deer, hares, &c. whose ears have much motion, always direct them so as to meet the sound.

How hearing is effected, see AUDITUS and SONUS.

On the ears, see Cassebonius, Du Verney, Valsalva, Celsus, and Winslow's Anatomy. They treat either of the anatomy or the disorders of the ear.

AU'RIS MARINA. AU'RMAR. A shell fish very common on the coast of Scotland, Guernsey, Normandy, &c. It is shaped like an ear, it adheres to rocks, and to render them eatable they are first boiled, then fried.

AURISCA'LPUM, from *aurem scalpere*, an ear picker.

A'URIST, an EAR DOCTOR.

AU'RUM, (from *aor*, *resplendence*, a Hebrew term). GOLD; called also *sol*, and *rex metallorum*, *deheb*, *cor*. The filings are named *catma*; the chemists call it *sol*, because they thought it to be under the influence of the sun. Its character is a circle with a dot in the middle, thus  $\odot$ , denoting a body perfectly inacrimonious, smooth, and equal.

The greatest part of what we have comes from America, particularly from the mines of Peru; but the Asiatic is esteemed the finest. Sometimes it is found pure and unmixed in small grains or in large lumps, and is then called VIRGIN GOLD; but it generally rises in ores of different kinds: its chief matrix is flint; and all sand contains a greater or less quantity of it.

Gold is somewhat more than nineteen times heavier specifically than water. The Arabians introduced it into medicine; Avicenna esteemed it for its cordial quality, and a comforter of the nerves; but as in every state it is insoluble by any of the animal fluids, it can only be an amulet against poverty.

It is not surprising, however, that the alchemists, to whom we are indebted for so many chemical remedies, should have tortured this metal for the service of the art of healing. The cordial qualities were supposed to assist medicines of this class; and even a heated mass of gold, extinguished in a fluid preparation, gave it the name of *solar*. The pure leaf gold has been employed with some success to exclude the access of air; and in some measure to prevent the pits of the small pox; and as a defence to sore nipples from the saliva of a child, particularly when affected with aphthæ.

The aurum-fulminans has been employed as a medicine since the time of Crolius, and its use has been lately revived. It is gold precipitated from its solution in aqua-regia (nitro muriatic acid) by a volatile alkali; or, if the sal ammoniac is added to the nitrous acid to form the aqua regia, the fixed alkali will answer the same purpose. Whether from careless washing, or from the metal itself, the worst effects have followed its exhibition; and colics, convulsions, faintings, and cold sweats, have been the consequences. In smaller doses it is said to be an useful sudorific in the worst fevers; and Angelus Sala observes, that it is a certain and easy laxative. Lemery has supposed, from chemical views, that it may be of service in diseases arising

from a too copious use of mercury; and modern practice, from the usual tonic powers of metals, has employed it, apparently with success, in chorea.

Some other preparations of gold may be shortly mentioned, though many of these supposed to contain it have not a particle of the metal in the whole composition. The *aurum potable, tinctura solis*, with many other sounding applications, are of this kind. The preparation is either concealed or described with a suspicious reserve; but it seems to be only an ethereal oil coloured with gold, or some substance resembling its golden hue. The *aurum vitæ* of Quercetanus is a calx of gold dissolved in vinegar, seemingly by the medium of spirit of wine. The *magisterium auri* is the aurum fulminans, digested repeatedly with the spirit of baum, and mixed with  $\frac{1}{10}$  of ambergrise, as much musk, and  $\frac{1}{2}$  of saffron. This preparation, in a dose of from three to five grains, is said to be tonic, antiseptic, alexipharmic, and antispasmodic. It is the foundation of many other preparations which are exuberantly extolled, but which modern practice rejects. We shall notice but one other, which merits some notice, as it is honoured with a place in the Wirtemberg Dispensatory; and if any preparation of gold is useful, this promises to be so. It is styled *cornu cervi auratum*; and consists of leaf-gold very carefully rubbed with powdered hartshorn, and calcined in a crucible till it assumes a purplish colour. It is used in malignant fevers; in measles and small pox as a cordial; but may probably be an useful tonic.

AU'RUM ELE'MPIUM. See SUECINUM.

AU'RUM HORIZO'NTALE. See AURATUS GERMANORUM.

AU'RUM POTAB'ILE. See LENTSIGUS.

AU'RUM LEPRO'SUM. See ANTIMONIUM.

AU'RUM VEGETAB'ILE. A name given to SAFFRON. See CROCUS.

AUR'US BRASILI'ENSIS. See CALAMUS AROM. ASIATICUS.

AU'STER, (from *ava*, to burn). The SOUTH WIND, which is warm, moist, and productive of putrid diseases. It means also AUSTERE, and arises from the union of acid with astringent particles, such as in unripe fruits.

AUSTROMA'NTIA, (from *αὐστη*, the wind, and *μαντῖα*, divination). Pretending to tell events from observation of the winds.

AUTA'LIS. See DENTALIUM.

AUTHE'MERON, (from *αὐτος*, the same, and *ἡμέρα*, a day). The VERY SAME DAY. A medicine is thus called that gives relief on the same day it is taken. Galen describes two remedies of this kind.

AUTOPHO'SPHORUS, from *αὐτος*, itself, and *φωσφορος*, phosphorus: real phosphorus). See PHOSPHORUS.

AUTO'PSIA, AUTOPSY, (from *αὐτος*, himself, and *παραί*, to see). OCEULAR EVIDENCE.

AUTO'PYROS, from *αὐτος*, itself, and *πυρος*, wheat). See BREAD.

AUTU'MNUS, (from *augeo*, auctum, because, Festus says, at this time the fruit of the earth, and the labours of men, are increased). AUTUMN. The season of the year between summer and winter, beginning astronomically at the equinox, and ending at the solstice: popularly it comprises August, September, and October. Celsus wisely advises people to begin early in this

season to wear warmer clothes, for the irregularity of the weather subjects them to a variety of diseases.

AUXE'SIS. See AUGMENTUM.

AUXILIA'RII MUSC, (*auxilium*, assistance). See PYRAMIDALIS MUSCULUS.

AU'XYRIS, (a corruption of *Osyris*). See ASYRIS.

AVACCARI, (Indian). A little tree, the leaves, fruit, and flowers of which resemble the myrtle; but it is more astringent. It grows on mountains in the province of Malabar, and is used against dysenteries; but not yet described so clearly that its systematic arrangement can be ascertained.

AVARA'MO, (Indian). The name of a siliqueous tree which grows in Brasil. Its bark is externally of an ash colour, and internally very red; both it and the leaves are astringent: a decoction of the bark hath been supposed to dry ulcers, and is said to have cured cancers. Raii Hist. It has not been noticed by systematic authors.

AVELLA'NA, (from *Abella*, or *Avella*, a town in Campania where they grow,) *corylus avellana* Lin. Sp. Pl. 1417. The HAZLE NUT. Miller takes notice of six sorts; viz. the hazle nut, the small manured ditto, the large cob nut, the Spanish nut, the red filbert, and the white filbert.

The iuli, or katkins, which grow on the trees early in the spring, and the shells, are restraining or binding. An emulsion made of the kernels of nuts or filberts, and mead, is commended in coughs. Filberts nourish more than nuts; but the oil is so closely united with the mucilage that they are very indigestible; the roundest kernels are most esteemed. They all afford a considerable quantity of an agreeable soft oil by expression.

AVELLA'NA CATHA'RTICA. See CATAPUTIA MINOR.

AVELLA'NA MEXICANA. See CACAO.

AVELLA'NA PURGA'TRIX. See CATAPUTIA MINOR and BEN.

AVELLA'NA INDIA'NA VERSICO'LORE. See ARECA.

AVELLA'NÆ I'NDICÆ GENUSOBLO'NGUM. An inferior species of NUTMEGS.

AVE'NA, (from *aveo*, to covet, because cattle are very fond of them). *A. sativa* Lin. Sp. Pl. 118. OATS. The two kinds, the black and white, have similar virtues, but the black ones are preferred for horses, as more nutritious; they are less so than rice or wheat, yet afford a sufficient nourishment to as active and vigorous a people as the world produces; viz. the Highlanders. Gruels made with the flower, called OAT MEAL, digest easily, have a soft mucilaginous quality, by which they obtund acrimony, and are used for common drink and food in inflammatory disorders, coughs, hoarseness, roughness and exulceration of the fauces. A subacid jelly made with oats is a pleasant summer food, and highly useful as an antiphlogistic diet in fevers. It is called *sorvins*, sometimes *frumenty*.

Water gruel answers all the purposes of Hippocrates' ptisan: it forms externally, with vinegar and oil, *emollient* poultices for sprains and bruises, and *stimulant* ones with the grounds of strong beer for tumours, of a gangrenous tendency, or in poor emaciated habits. For that named GRÆCA and STERILIS, see ÆGYLOPS.

AVENQUA. See ADIANTHUM CANADENSE.

A'VENS. See CARYOPHYLLATA.

AVER'SIO, (from *averto*, to turn from). The diverting of a flux of humours from one part to another; a nausea or inappetency; the recession of the uterus from its proper place.

A'VES, CY'PRIÆ. See CANDELA FUMALIS.

AVICE'NNIA TOMENTO'SA. See ANACARDIUM.

AVIGATO PEAR, *laurus persea* Lin. Sp. Pl. 529. A nutritious tropical fruit, supposed to be antidyenteric. The sailors eat the unripe fruit as an antiscorbutic.

A'VIS ME'DICA, (from *avib*, Hebrew). The PEACOCK. See ALIMENT.

AVOIRDUPOIS. This, in the French language, signifies to have weight; because the pound so called contains sixteen ounces, and hath more weight by some ounces than that which is called Troy weight, which contains twelve ounces; more probably from its being employed in weighing the heavier articles.

AVO'RNUS. See ALNUS NIGRA.

AVRA'RIC. See ARGENTUM VIVUM.

A'VRUM. See SUCCINUM.

A'XEA COMMISSU'RA. See TROCHOIDES.

AXE'DO. The name of a spell in Marcellus Empiricus, to render a person impotent.

AXILLA, (*Atzil*, Hebrew; but Scaliger derives it from *ago*, to act, and from thence *axis*, and *axilla*). The ARM PIT, called also *mascale*, *titillicum*, male. When an offensive smell is perceived from the arm pit, Dioscorides and Ætius recommend the decoction of wild artichoke in wine, which, by bringing off much fetid urine, may produce a cure. See also ALA.

AXILLARES GLANDULÆ. Conglobate glands in the axilla, through which the absorbents of the upper extremity pass.

AXILLA'RIA ARTE'RIA. The SUBCLAVIAN ARTERY having left the thorax immediately above the first rib, in the interstice between the portions of the scalenus muscle, there receives the name *axillary*, because it passes under the axilla. This axillary artery detaches the external mammary arteries to the breast; and lies behind, on the inside of the coraco brachiaëus; when it has got to the under side of the subscapularis, it gives off a branch to that muscle, the serratus major anticus, &c. The axillary artery gives off the inferior scapular, which passes backwards, chiefly to the infra spinatus. Just below the head of the humerus, the axillary throws off the humeral or articular artery, which, passing round the joint, anastomoses with its fellow. The axillary artery commonly runs down behind the tendon of the pectoralis major, then passes over the coraco brachiaëus, goes down on the inside more and more forward, just covered by the inner edge of the biceps, passes under the aponeurosis of that muscle; and a little below the bend of the arm, between the pronator teres and supinator radii longus, divides into the radial and ulnar arteries.

AXILLA'RIS NE'RVUS. The AXILLARY NERVE; also called the ARTICULAR NERVE, arises from the last two cervical pair; it runs in the hollow of the axilla, behind the head of the os humeri, between the musculus teres, major and minor, and turning from within outwards and backwards round the neck of the bone, runs to the deltoid muscles.

AXILLA'RIS VENA. The AXILLARY VEIN, is the continuation of the subclavian from its passage out of the thorax to the opposite side of the axilla.

A'XIS, (from *ago*, to act). That round which any thing revolves or is supposed to revolve. With ANATOMISTS it is the name of the second vertebra, and according to some the first vertebra, of the neck; it hath a tooth which goes into the first vertebra, and this tooth is called the *axis*, by others the axle. Blancard says it is the third vertebra from the skull.

A'XIS ARTE'RIÆ CÆLI'ACÆ. See CÆLIACA ARTERIA.

AXU'NGIA, from its use, *unguendi*, *axem*. Hog's LARD. See ADEPS.

AXU'NGIA CASTO'REI. See CASTOR.

AXU'NGIA DE MUMIA. See MEDULLA.

AXU'NGIA VITRI. SANDIVER, or SALT OF GLASS; it separates from glass whilst making; it is acrid, and hath been used to clean the teeth.

AYAPA'NA. A plant brought to the Isle of France from the Brasils, supposed to be a certain remedy for phthisis and the bites of serpents; but, as Bôry in his late voyages informs us, is really useless.

AYBO'RZAT. See GALBANUM.

AY'CAPHAR, and AY'COPHOS. See ÆS USTUM.

A'ZAC, (from *asak*, Arabic). See AMMONIACUM.

A'ZADAR ACHE'NI A'RBOR. See AZEDARACH.

AZA'GOR. See ÆRUGO.

AZA'NITÆ A'COPON. The name of an acopon or ointment, in P. Ægineta.

AZA'NITÆ CERA'TUM. The name of a cerate in Oribasius.

A'ZAR. See ADROP.

AZA'RNET. See AURIPIGMENTUM.

A'ZED. An inferior kind of camphor among the Arabians. The finest was called *alcansuri*; the second *abriagi*. The first was the natural exudation from the tree; the second was a very pure kind carefully sublimed. The azed was the present camphor of commerce.

AZE'DARACH, AZE'DRACHINI, (Indian). Called also *pseudosycomorus*, *azadar*, *tacheni arbor*, *arbor fraxini folio flore cæruleo*, *zizipha candida*, *anabepou*. *Acostæ zodoaria candida*. *Melia azederach* Lin. Sp. Pl. 550. It is a tall tree in the island of Ceylon, and other parts of the East Indies. It resembles an ash; the fruit is like an olive, and from it oil is expressed for staining cotton: the pulp of the fruit is said to be poisonous, but the taste is not disagreeable. Another species is a native of the coast of Malabar; the *m. azederacta* Lin. Sp. Pl. 550. The oil expressed from its fruit is used to cure bites of serpents, and to restore flexibility to contracted limbs. The leaves, infused in juice of lemons, are supposed to be vulnerary and antelmintic. Willdenow has described two other species of similar virtues. See Raii Hist.

AZE'DEGRIN. See HÆMATITES.

A'ZEFF. SCISSILE ALUM. See ALUMEN.

A'ZEG. See VITRIOLUM.

AZEMA'FOR. RED LEAD. See PLUMBUM.

AZEMA'SOR, and AZYMAR. See CINNABARIS.

AZE'NSALI. A sort of moss that grows on rocks.

A'ZIMAR. BURN'T COPPER. See ÆS USTUM.

**A'ZOTUM, AZO'TICUS GAS**, (from  $\alpha$ , non, and  $\zeta\omega\eta$ , *vitâ*). **AZOTE, AZOTIC GAS**. This is the noxious part of the atmospheric air; see **AER**. Formerly called *phlogisticated air*; and *atmospheric mephitis*. It has been called **AZOTE** by modern chemists, because the chemical properties of the noxious portion of atmospheric air being hitherto little known, they have thought it right to derive the name of its base from the known quality of killing such animals as breathe in it. It is a tasteless, inodorous element, existing in a large proportion in the atmosphere, and is obtained copiously from the fibrous parts of animals by means of nitric acid. Mixed with vital air or oxygen, in the proportion of 72 to 28, it forms air similar to atmospheric air; combined with hydrogen, it constitutes volatile alkali; and with carbon, the gluten of animal fibres; it is the basis of the nitrous acid. The weight of this gas, at the temperature of 54, 50, and under a pressure equal to 28 inches of the barometer, is 1 oz. 2 drachms and 48 gr. to the cubical foot, or 0.444 of a grain to a cubical inch; and to common air it is as 942.6 to 1000. See Lavoisier's *Elements of Chemistry*. According to Kirwan, it is as 985 to 1000. We have much reason to suppose, as already hinted, that a larger proportion of azote in the air we breathe might be medicinally useful; but on this subject there are many doubts; and until it can be separated from ignorance, presumption, and quackery, such doubts must remain.

**AZOTH**, is a name for **BRASS**. It sometimes signifies the quicksilver of any metallic body. See **REBIS**.

**A'ZRAGAR**. See **ÆRUGO ÆRIS**.

**A'ZUB**. See **ALUMEN**.

**A'ZUR**. See **CORALLIUM RUBRUM**.

**A'ZURIUM**. A chemical preparation described by Albertus Magnus. It consists of quicksilver two parts, sulphur one-third, sal ammoniac one-fourth, mixed in a mortar, and set in a vessel over the fire till a bluish smoke arises: it must be then taken from the fire, the glass broke, and the contents powdered.

**A'ZYGES**, (from  $\alpha$ , neg. and  $\zeta\upsilon\gamma\gamma\omicron\varsigma$ , *a yoke*). See **SPHÆNOIDES OS**.

**AZYGOS MORGA'GNII**. See **STAPHYLINI**.

**AZ'YGOS**, vel **A'ZIGOS**, (from  $\alpha$ , neg. and  $\zeta\upsilon\gamma\gamma\omicron\varsigma$ , *a pair; without a fellow*). The musculus *azygos* of Morgagni rises tendinous from the junction of the ossa palati, and runs down the palatum molle to the middle of the uvula, serving to elevate it.

**A'ZYGOS PROC'ESSUS**. See **SPHÆNOIDES OS**.

**A'ZYGOS VE'NA**. *Vena sine pari*. A vein situated within the thorax on the right side, *having no fellow* on the left. It arises posteriorly from the vena cava superior, a little above the pericardium; it is immediately bent backwards over the origin of the right lobe of the lungs, forming an arch which surrounds the great pulmonary vessels on that side, as the arch of the aorta does on those on the left, with this difference, that the curve of the azygos is directly backwards, but the other is oblique: from thence it runs down by the right side of the vertebræ dorsi, and before the intercostal arteries; and passing behind or below the diaphragm, it terminates by an anastomosis, sometimes with the vena renalis, at others with the neighbouring lumbar vein, sometimes immediately with the trunk of the vena cava inferior.

The vena azygos sends out branches from its upper part to the aspera arteria and bronchiæ by the name of *venæ bronchiales*; afterwards it sends out the *intercostales dextræ superiores*; lower down, the *intercostales dextræ inferiores*.

Sometimes there is an azygos on the left side, proceeding from the arch of the common azygos: it is afterwards distributed in the same manner as the other on the right side; but this disposition is very variable.

The azygos having reached the last rib, sends off a large branch, which, bending outwards, perforates the muscles of the belly, is ramified betwixt different planes, and communicates with the branches of the intercostal veins which run there.

**A'ZYMOS**, (from  $\alpha$ , neg. and  $\zeta\upsilon\mu\eta$ , *ferment*). **UNFERMENTED BREAD**, as **SEA BISCUIT**, which, Galen observes, is not very wholesome, except were the digestive powers are too strong. See **BREAD**.

## B A G

**B.** See ARGENTUM VIVUM.

BABUZICA'RIUS, (from βαβάζω, to speak inarticulately; because the voice is apt to be inarticulate and confused in this disorder). See INCUBUS.

BA'CANON. CABBAGE OR RAPE SEED.

BA'CCA MONSPELI'ENSIS. See BACCHARIS.

BA'CCÆ, are small roundish fruit that grows scattering upon trees and shrubs, and in that are distinguished from acini, which are berries hanging in clusters.

BACCÆ NORLANDICÆ, the berries of the *rubus arcticus* Lin. Sp. Pl. 708. Supposed to be cooling antiseptic, perhaps antiscorbutic.

BA'CCÆ BERNU'DÆ. See SAPONARIÆ NUCULÆ.

BA'CCAR, BA'CCHARIS, (from *bacchus*, wine,) from its fragrance resembling that liquor. Also called *bacca Monspeliensis*, *conyza tertia* Dioscorides, *eupatorium*. *Inula dysenterica* Lin. Sp. Pl. 1237. GREAT FLEA BANE, PLOUGHMAN'S SPIKENARD. It is a sweet-scented shrubby plant, used for making garlands; and delights in rough and dry grounds. The roots smell like cinnamon, and are a powerful emmenagogue; the leaves moderately astringent.

BA'CCHIA, (from *bacchus*, wine, because it generally proceeds from hard drinking and intemperance). See GUTTA ROSACEA.

BA'CCHICA, (from *Bacchus*, because he was generally crowned with it). See HEDERA TERRESTRIS.

BA'CCHUS. The fish called MULLET. See MUGILIS.

BA'CCIFER, (of *bacca*, a berry, and *fero*, I bear). An epithet added to the name of any tree, shrub, or plant, that bears berries.

BACHE'RI PILULÆ TONICÆ. See ASCITES.

BAC'ILLI. See TROCHISCI.

BACILLUM. See CANDELA FUMALIS.

BA'DIAGA. A kind of sponge usually sold in Russia, the powder of which takes away the livid marks of blows and bruises within a few hours. It differs, however, from the sponges and alcyoniums, as it is full of small hard grains, connected by friable herbaceous fibres, and grows under the water. It is only described by Bauxbaum, and its nature is not properly understood.

BA'DIAN. SEM. See ANISUM INDICUM.

BÆ'OS. In Hippocrates it means *few*; but in P. Ægineta, it is an epithet for a malagma.

BAGNIGGE WELLS WATERS. These wells are situated at the bottom of the hill on the south-

## B A L

west side of Islington; the water is clear, and tastes slightly brackish, like a weak solution of Epsom salt. From a gallon of this water evaporated, Dr. Bevis obtained 135 grains of insoluble earth, 257 of bitter purging salt, mixed with a marine salt, from whence they derive their purging quality. Dr. Monro thinks it probable that the salt of this water is mostly an Epsom salt, with a good deal of a bittern; because it runs easily per deliquium, and is very difficult to crystallize. In most constitutions three half pints are considered a full dose for purging.

BA'GNIO. (from *bagno*, Italian). A SWEATING HOUSE.

BAGS. Various medicinal substances were usually confined in thin bags, and applied to the part affected. These were chiefly cordials applied to the pit of the stomach in deliquia; anodynes and antispasmodics to the pit of the stomach in hysteria and colic; and sedatives or discutients to the head in its diseases. Malt liquors are medicated or perfumed by substances in bags; and clothes scented in a similar way.

BA'HEI COYO'LLI. See ARECA.

BA'HEL SCHU'LLI. An Indian tree; also called *genista spinosa Indica verticillata flore purpureo cæruleo*. It resembles the *barleria buxifolia* Lin. Sp. Pl. 887; but is probably not the same, as the latter is represented in Rheed's 42d table, but the real species occurs in the 45th. It is of the family of the canthoides, and is a thorny shrub, of which there is one species growing in sandy ground, another in watery. A decoction of the roots is diuretic; the leaves boiled and sprinkled in vinegar have the same effect. Raii Hist.

BA'TAC. See PLUMBUM.

BA'LA. See MUSA.

BALÆ'NA, MAJOR and VULGARIS, (from βαλλω, to cast, from its power in casting up water). See CETUS.

BALÆ'NA MACROCE'PHALA. See CETE ADMIRABILE.

BALAMPU'LLI. See TAMARINDUS.

BA'LANDA, (from βαλανος, a nut). See FAGUS.

BALAN'NUM, OL. (from βαλανος, an acorn). OIL of the BEN NUT.

BALANOCA'STANUM, (from βαλανος, a nut, and καστανον, a chesnut). See BULBOCASTANUM.

BALA'NOS, (from βαλλω, to cast, because it sheds its fruit upon the ground; or from the Hebrew term, *balon*, proceeding from the oak). See QUERCUS, SUPPOSITORIUM, PESSARIUM, PENIS GLANS and ADIP-SOS. Theophrastus uses it sometimes to express

any glandiferous tree. From the similitude of form, this word is used to express *suppositories* and *pessaries*.

BALARUC, WATERS OF, in France, are warm, about 128° of Fahrenheit; chiefly saline and purgative, without iron or sulphur.

BALAU'STIA, BALAU'STIUM, (from *βαλιος*, various, and *αω*, to dry; so called from the variety of its colours and becoming soon dry: or from *βλαστειναι*, to germinate). Called also *malus punica sylvestris*; *granatus sylvestris*, *punica granatum*, the double flowered wild POMEGRANATE, or the BALAUSTINE TREE. The *punica granatum* Lin. Sp. Pl. 676.

*Balaustium* is properly the cup of the flower of this tree. The *balaustines* of the shops are large rose like flowers of a deep red colour, set in long, bell shaped, tough cups. The plant is a native of the southern parts of Europe, and is cultivated in our gardens for the beauty and duration of its flowers. The dry flowers are brought from abroad into England, but those of our own growth do not seem to be inferior to the foreign.

Those flowers are mildly astringent, but less powerful than the bark of the fruit, and have a rough bitterish taste. They give out their virtue to water and to rectified spirit of wine. The extracts made from these tinctures retain all their astringency, but the watery infusion yields most, and the spirituous a somewhat stronger extract.

The dose of these flowers may be from one scruple to two drachms, and to this quantity most of the vegetable astringents may be given. The rind of the fruit is considered as strongly astringent, and has been particularly useful in gargles, in diarrhoea, and in external applications. Sydenham, against prolapsed rectum and uterus, prescribed an ounce of the rind bruised with two pints of the decoction of oak bark and half a pint of red wine, as a fomentation; and Dr. Mead orders a decoction compounded of this bark with cinnamon and red roses, of each a drachm; in milk strained one pint, and the same quantity of water to be gradually added, the whole reduced to one pint, and sweetened with sugar, to be taken daily in colliquative diarrhoeas.

BALBU'TIES, (from *βαλβάζω*, to stammer). A DEFECT OF SPEECH, properly that sort of stammering, where the patient sometimes hesitates, and immediately after speaks precipitately; the *psellismus balbutiens* of Dr. Cullen.

BA'LCHUS. See BDELLIUM.

BALDNESS. See ALOPECIA. It is said that women and eunuchs are scarcely ever bald; and that in the parts from whence the hair falls, the brain retracts from the skull. The temples first lose their hair; then the vertex. Bald head was in the eastern regions a term of reproach; probably implying early excess, to which it has been attributed.

BALLON, a glass receiver, often with two necks to join another ballon.

BALLA-MUCCA-PI'RA. See MOMORDICA.

BALLI'STÆ, Os. The astragalus, because the ancients used to cast it from their slings, (from *βαλλω*, to cast). See ASTRAGALUS.

BALLOTE, (from *βαλλω*, to send forth, and *ωτος*, the genitive of *ους*, the ear,) because it sends forth flowers like ears. Called also *marrubium nigrum fetidum*, *ballota nigra* Lin. Sp. Pl. 814, and BLACK

STINKING HOREHOUND. It grows in paths, highways, and hedges, flowering in July. A strong decoction of it, freely taken, is of great efficacy against hysteric affections.

BALLS, *Martial*. A mixture of two parts of cream of tartar and one of filings of iron made into a ball, which, when given, is infused in water till it imparts some colour to it.

BALLS, *Mercurial*. An amalgam of mercury and tin, boiled in water to purify it and destroy animalcules.

BALNEUM, (from *βαλλω*, to cast away, and *ανια*, grief). This word properly signifies the HOT BATH only; and under this head we shall consider only the general and partial warm baths, referring for cold bathing to the article BATHING, q. v.

In Greece and Rome the baths were of considerable importance both in preserving and restoring health; nor can the practical regulations of the ancient physicians be properly understood, without a description of the different parts of their apparatus. It was reduced to a system; and its effects must necessarily be more powerful than the simpler mode in which warm bathing is now practised.

The baths consisted of four parts, (Galen, Methodus Medendi, lib. x. cap. 10). In the first, the person was gradually heated in hot air until a sweat was produced; and generally at this time anointed and rubbed. The apartment was called *laconicum*; the operation *assa*, and *assæ sudationes*. When the baths were more simple, they had one hot room, or stove only, which was round, and covered with an hemispherical roof, (Vitruvius, v. 10). Others had two rooms, the *tepidarium* and *caldarium*; and many three, which were placed in succession. The first was used as a dressing room, *aphodyterium*, when there were more than one stove.

The hot rooms were heated from a stove underneath, by means of flues carried round within the walls. From the hot bath, which was adjoining the hottest room, the floors declined, that the water thrown over the side might cover each room, and keep the air full of warm vapour.

After the sudæ sudationes, they went into the hot bath; then into a warm one; and gradually into a cooler. The first two were called also *caldarium* and *tepidarium*; but there was a third part called *frigidarium*. The patient commonly sat on a low seat, called the *solium*, with the legs, and sometimes the thighs, covered with water. At the same time the servants poured the water from pitchers or urns on the heads. If any part was particularly affected, a larger quantity of water was thrown on it. This mode of using the bath is preserved in various antiques and bas-reliefs, as well as in the descriptions of Galen. Sometimes they were anointed during this period, and returned again to the bath. After bathing in the cooler water they were rubbed with cloths, and gradually accustomed themselves to meet the cooler air of the atmosphere by a short stay in the frigidarium. The curious reader may find in Galen (Method. Medendi, i. 4. and x. 10), a particular description of the management of the bath, in disorders of the head, and in hectic fevers.

The term frigidarium implied comparative cold only, for the stove was continued under this part of the bath also. Vitruvius expressly orders three cauldrons to be placed in the furnace, in such situations that the water may fall from the frigidarium into the tepidarium, and

from the latter into the caldarium. The hearth also was lowest at the præfurnium, and gradually ascended under the caldarium, tepidarium, and frigidarium, for the purpose of keeping the fuel under the first, and that its effects might extend with diminished power through the whole cavity. Not only from its situation, but from the continuance of the sweat after bathing in the cooler water, which was expected (see Galen l. c.), it may be concluded that the chill of the water was taken off in the frigidarium, and that the term, as we have said, was comparative only. Avicenna, the implicit follower of Galen, gives a particular caution, *ne aqua multum sit frigida: imo ut sit temperata*, (lib. 1. canon. fen. 3. doct. 2. cap. 6). In the baths, built rather for pleasure than for medicinal purposes, the water in the frigidarium seems to have been quite cold; and it certainly must have been so in the baths described by the younger Pliny, lib. v. epist. 6.

In Baccius de Thermis, and Mercurialis de Arte Gymnastica, *balnea pensilia* are mentioned; and physicians have been greatly divided respecting the meaning of a term which would seem to imply that some exercise was occasionally employed during bathing. We find however in Vitruvius, that any buildings supported by pillars were called *edificia suspensa*; and before the more complicated construction just described was introduced, in the time of Sergius Orata, the contemporary of Crassus the orator, about 700 years *ab urbe condita* (Valerius Maximus Memorabil. ix. 1.), the water was probably heated in common vessels; and the baths, supported by these pillars, then acquired the name of *balnea pensilia*. There is a remarkable passage in Pliny's Natural History which seems to support this idea. He is speaking of the rude method of exciting sweating previous to the time of Asclepiades, by clothes, the sun, or large fires, and adds, that the baths which he introduced were infinitely luxurious, and received with the greatest avidity: "*Imo vero, toti Italiæ imperatrici, tum primum pensilium balnearum usu, in infinitum blandiente.*" Again, "*Balneas avidissima hominum cupiditate instituit.*" Seneca supposes the invention to have been first known in his time, but he unites the *suspensuras balnearum* and *impressos per parietes tubos*, (Senec. epist. xc.). Vitruvius, also, in his directions for the hearth of the stoves, adds a reason, "*Quo facilius flamma pervagaretur sub suspensione.*" It is singular that Baccius and Mercurialis should have supposed that these *balnea pensilia* were suspended by ropes. We find no instance in the ancient physicians of the management of exercise during bathing, and the words of Valerius Maximus, in the passage formerly quoted, are almost decisive. "*Balnea pensilia* Orata primus facere instituit; que impensa levibus initiis capta, ad suspensa aquæ calidæ tantum non æquora penetravit." What ropes could support such oceans of hot water?

The whole of this arrangement appears to be very judicious. We are not acquainted with the degrees of heat employed, as the ancients had no instruments to measure it. There is reason however, from the effects, to think it considerable; and when people are used to bathing, the extremes of heat constitute the luxury. In general, the bath consisted of vapour only, since the water was only occasionally and partially poured on; and we know that the degrees of heat that can be borne either in hot air or in vapour are very consider-

able. M. Tillett's experiment on the heat endured by a girl in a hot oven, and the heat which Dr. Fordyce and his companions experienced in their hot rooms, were almost incredible. See HEAT.

If, then, the heat of the baths was raised to so great a degree, some previous preparation was necessary. It is thought expedient at Bath, by previous evacuations to prevent the bad effects of a high temperature; and this the Romans obtained in their laconicum, where, by previous rubbing and warm air, the sweat would immediately break out on entering the bath. Asclepiades depended on the discharge by the skin to free the vessels from obstructions; and his followers, Erasistratus and Chrysippus, would not admit of the more general evacuations, since that from the skin would not only supply their place, but be in other respects more beneficial.

To prepare for these evacuations the *assæ sudationes* were employed; in the language of Galen, "to produce an uniform heat to expand the contracted apertures of the smaller passages, to relax what is tense, to melt what is condensed." The patient can then with advantage bear a considerable degree of heat; but in water *too hot* the smaller vessels are contracted rather than relaxed, and the excrementitious fluids retained rather than expelled, (Galen de Sanitate tuenda, iii. 4). This plainly proves what we have already stated, that the heat of their common baths was considerable; for we could not without some preparation endure the degrees of heat which would produce these effects; and the baths of that time, after the period of Pompey, are styled *incendio similia*. The great danger apprehended by the Roman physicians of the bath after eating, is an additional proof that the temperature was high; and Seneca mentioned as one of the duties of the ediles, enforcing cleanliness, *et utilem, et salutarem temperaturam*. Perhaps this temperature may have been of service in stimulating the solids and giving additional vigour, since the *athletæ*, after their exercises, were bathed in very hot water; and the bath waters of this country, which are of a considerable heat, seem of service in cases of relaxation, independent of their impregnations. But we must not anticipate what will be the subject of future consideration.

The warm bath was interposed between the hot and the cool to prevent a too sudden change, and, in Galen's language, to restore a due symmetry to the skin and flesh. The utility of the third part is obvious, to prevent all danger from the cold of the atmosphere. The fever, however, excited by the great heat still kept up the perspiration, which was not wholly checked after leaving the frigidarium.

The stay in the different rooms was regulated by the physician according to the nature of the disease. Baccius has preserved a list of the complaints for which the warm bath was employed (lib. vii. cap. 19.), but has not explained the management adapted to different constitutions and different diseases. When the object was to relax, for instance, the patient was detained for some time in the moderately warm bath, but passed very quickly through the sweating rooms, where he was anointed, and only rinsed himself with the waters of the last bath. When the constitution was weak and relaxed, he was well sweated and rubbed in the first part, and had a larger quantity of colder water poured on him in the third. His stay in the second part was

very short. The various modifications detailed at length in Galen and others, would detain us too long, and be uninteresting, as we cannot imitate them.

The danger, however, of coming into cool air from the bath is in a great degree imaginary; for the fever, or, more properly, the temperature, thus raised, will check the bad effects of a considerable degree of cold. The Russians and the Swedes use the warm vapour bath raised to a very considerable heat, and roll immediately afterwards in snow. This impunity may perhaps be, in part, derived from habit; but we have found little inconvenience arise in those not accustomed to such a change, when the heat previously excited was considerable.

It will be obvious, that we can learn nothing from the Greek or Roman physicians respecting the effects of bathing on the pulse, or the degree to which the heat of the body is increased. On the other hand, we cannot in our simpler operation attain all the effects of the balneum which they produced. We must now attend to the more modern use of this remedy, and its power in different diseases.

Warm bathing gives a softness and flexibility to the skin and muscles; and from some rarefaction of the blood, or from its determination to the surface, increases the bulk. It seems to increase all the secretions, as it certainly does those of the skin; nor after the sweat excited by bathing is the perspiration diminished, though the increase of any evacuation, in general, occasions a temporary suppression afterwards: the pulse becomes fuller and quicker; the face flushed; the respiration laborious. A moderate stay in the bath increases the spirits as well as the activity, and improves the general health: continuing in too long induces languor and debility.

We do not recollect any direct experiments on this subject but those in a Thesis by Dr. Parr, which have been generally copied in every subsequent publication. He tried the effects of warm bathing at 96°, 98°, 100°, 102°, 104°, and 106°, of Fahrenheit. At 96° the general effects above mentioned were observed; the pulse, if at first slightly quickened, was soon natural; the respiration, in the earliest period a little more rapid, soon became free and easy, and but little change was produced in the heat of the body.

At 98° the pulse was slightly increased in quickness, and did not subside; but the heat appeared to remain stationary. There was no sweat, though a free copious perspiration: the urine was not increased; and, after some time, the pulse became slower than before the bathing. The cuticle was observed to be slightly corrugated.

At 100° the pulse was increased from 60° to 72°; the respiration much affected; the face red and swollen, and a copious sweat broke out: the cuticle appeared more corrugated. The heat was raised two degrees; and, after about ten minutes, faintness came on. The perspiration was free and copious; and, after a short time, every disagreeable symptom vanished; the pulse sinking a little below its natural standard.

At 102° the pulse was soon raised from 68° to 100°, and, in ten minutes, the sweat on the face was copious, the vessels turgid, the skin not corrugated, and the heat of the body raised from 98° to 102°. A beating noise was heard in the head; and in half an hour, giddi-

vql. i.

diness came on. When laid between blankets, the sweat was copious and free, the pulse soon became natural, and the quantity of urine was not increased.

At 104° all these appearances were still more striking and more rapid: a vertigo coming on, at the end of about twenty minutes, put a stop to the experiment. At 106° the effects came on still more quickly and more violent. The faintness and sickness supervened more early; the sweat was more copious, but the frequency of the pulse did not subside even after twenty-five minutes. From these experiments, seemingly made with care and attention, we perceive that little is to be dreaded from the stimulating effects of the hot bath under about 102°; and that, probably, under 94° it has no peculiar or appropriate power. As the limits of the cold bath we shall find to be about 84°, the temperature, in the interval, has the effects of neither. Above 102° the warm bath determines powerfully to all the extreme vessels, particularly to the head and breast; and at this temperature it must be used with caution when the contents of either are disordered. The balance between the urine and the skin is nearly even at about 98°. Dr. Cullen supposed the effects of the warm bath to arise wholly from the relaxation of the skin, and, of course, the diminished pressure of that peripherical band which confines the fluids. Though correct to a certain extent, this view is too simple to explain all the benefit derived from the remedy. It will undoubtedly account for the determination to the skin, and joined with the stimulus of the heat, to the evacuations occasioned by warm bathing. When we reflect, however, that the subcutaneous nerves, as closely connected with the skin as the vessels, are subject to this relaxing warmth, we must suppose some of the benefit to be derived from this source also. In higher degrees, the stimulus we shall find to be very advantageous. The state of the extreme vessels is soon communicated to other organs; and as these in every part of the body sympathise with the vessels of the surface, a considerable relaxation must be thus obtained. In a certain degree their increased action gives a tone to the nerves; and we may therefore suppose that their relaxation produces an opposite state. In this way the effects on the nerves may be explained without supposing any immediate effect of the bath on the nervous system; and we thus see how moderate heat may relax, and a higher temperature give a tone to the nerves.

Two other opinions must be noticed. One of these is the general language of relaxing contracted ligaments, as if from the external action of warm water, the subjacent parts were macerated like the skin. There is not the slightest evidence of the fluid penetrating beyond the surface: indeed the oily fluid below the skin must prevent it; and from what has been said, its immediate contact will appear to be unnecessary in the explanation of the effects of bathing.

Dr. Stevenson has attributed all the effects of warm bathing to a rarefaction of the blood; and this idea is supported by all the appearances of external fulness. The language is echoed in every medical work without careful examination. In fact, the blood is one of the least expansile fluids by heat which has ever been tried. Sauvages inclosed it in a thermometrical tube, and found that at 212° it did not expand  $\frac{1}{100}$  part. Haller

G g

exposed it to a still greater heat with the same result. Indeed the expansibility of fluids follows no given law. Ether and quicksilver are nearly equal in this respect; at least, as we were informed by Dr. Black, who had tried the experiment, the difference was very inconsiderable.

In the cure of diseases, therefore, the beneficial effects of warm bathing are to be expected from its relaxing power; the increase of the circulation in the extreme vessels; with the perspiration excited and its general stimulus. In *melancholy*, its effects as a relaxant are most conspicuous; and in some spasmodic diseases without inflammation, particularly *tetanus*, it has been useful. In *ileus* it has been highly commended; but we have suspected that it hastens the progress of mortification, and are convinced that its free use has had injurious effects. Dr. Heberden, however, in the Medical Transactions, mentions the case of a woman who went into the bath nine times in one day, while labouring under an ileus in consequence of a hernia. In the *spasmodic asthma* of children it has been employed with success. In the *croup* also it has been commended, but scarcely any benefit has been derived from its employment.

Modern theory supposes a spasm on the extreme vessels to prevail in case of fevers; and warm bathing must, of course, be a remedy of importance. We are not prepared to discuss the question of the cause of fevers, but may remark, that the circulation during the paroxysm is not carried on in the smaller branches of the sanguiferous system. In *intermittents* it has consequently prevented the return of a fit; and in *continued fevers* it is often highly useful. In the beginning of continued fevers it is, however, less advantageous than in their decline; and in this state the bath must be supplied by the pediluvium, or, more commonly, by warm fomentations to the legs and thighs. In *inflammatory fever* it is less useful; yet at 98°, where the action of the heart and arteries is scarcely, if at all, increased, it may safely be employed; and Dr. Whytt, on the fourth day of this fever, has used it with advantage. In the latter period of *typhus*, when the low delirium occurs, it has been freely employed, and at least with some alleviation of the symptoms, if not with more decisive advantages; and should even inflammation have taken place in the brain, as it is of a less active kind, no injury is likely to result. Dr. Whytt supposes that fomentations are less useful than pediluvia; but in the low state to which the patient is usually reduced before the bath is employed, the former are only admissible. It will be remarked, that in vapour greater heat can be borne than in water; and, consequently, when the fomentation is properly employed, the heat of the flannels is seldom less than 120° of Fahrenheit.

Of the *exanthemata*, the only disease in which bathing has been employed, is the *small pox*. In Upper Hungary, Fischer has described it as the domestic remedy for this disease; and, in an epidemic small pox of considerable virulence, by imitating this practice, he was very successful. Dr. Stack, in his Thesis published at Leyden, has shown that variolous fevers, threatening a copious eruption, were mitigated by warm bathing, and the disease proceeded mildly and safely. When the eruptions are repelled, also, it has been very useful.

The heat of the bath should be carefully regulated, and should certainly not exceed 100°. The foundation of this practice we shall afterwards explain. See CUTANEOUS DISEASES.

In *hæmorrhages* and *phlegmasiæ* the use of bathing is equivocal; yet, with caution, it has been employed in the latter successfully.

In *amenorrhæa* from cold it has been useful; and such is the popular prejudice in favour of pediluvium, that it is too indiscriminately used. It is chiefly adapted to the strong and robust, where the suppression has been owing to a violent occasional cause. In the pain from *stone* in the *ureters*, or the *gall ducts*, from its relaxing power, it is a valuable remedy.

From its power of determining to the surface it is useful where any acrimony is to be discharged, or any unequal balance of the circulation is to be removed. In the former view we find it employed in *cutaneous diseases* and *syphilis*; in the latter, in *chronic catarrhs* and *diarrhæas*. In the first it chiefly assists the effects of mercury, and in the latter only supplies the advantages of a milder climate. In *hydrophobia* it has been employed, though with no very particular success. The ancient physicians used it in their complicated form, but concluded with immersing the patient into the piscina, the cold bath.

As a stimulus, the warm bath has been found very useful; and in the diseases for which it is most successfully employed the heat must be raised very high, far beyond that used in the experiments described. To this high degree of heat the peculiar virtues of the Bath waters are to be attributed, rather than to their impregnation. They are assisted also by the percussion in pumping on an affected part; a mode of application which greatly adds also to the tonic power of the cold bath.

In cases of *hemiplegia* there have been many doubts respecting the use of the warm bath. These chiefly arise from the disease being often occasioned by effusion on the brain, which the necessary stimulus might increase; and many instances have been adduced of its producing in such cases a fatal apoplexy. Undoubtedly, where marks of a determination to the head are strong; where the patient has not passed the meridian of life; or where the vessels have been stimulated by a continued excess of wine and spirituous liquors; warm bathing is a precarious remedy. In palsies in general, however, it may perhaps be allowed; and, as we have said, in *amaurosis*: so we shall find in *hæmiplegia*, that the effusion having once taken place, the disease is continued in consequence of the injury which the nervous system has received from the compression. We may then disregard the cause, except in the younger and more inflammatory constitutions just described. It should, however, be managed with caution: a drain from the head should be established by a perpetual blister, and the bowels freely emptied previous to its employment.

There is little management required in the use of the balneum in *chronic rheumatism*. It is a disease nearly allied to palsy, as the vessels, from the previous distention, are rendered paralytic, and contract spasmodically on fluids, probably in too large a proportion. The warm bath is particularly useful, and often alone will cure the disease. In that species of it confined to the

hip joint, *sciatica*, bathing and pumping on the part affected, are very valuable remedies.

In the hip joint, also, the relaxation of the ligament often occasions or endangers dislocation. It is the *morbus coxarius* of De Haen; the *arthrofluosis* of other authors. If it has not yet advanced to a suppuration, the Bath waters have certainly relieved a large proportion of those who have applied for their assistance; nor need we despair of imitating their effects by employing an equal temperature, and pouring it from a height. It would not require any great ingenuity to contrive a hand pump fixed in a reservoir, which is continually filling from cocks conveying boiling and cold water. The size of the aperture, or the number of cocks conveying cold water, might easily regulate the heat. A common garden engine might be readily converted to this purpose.

*Contracted limbs* are greatly benefited by warm pumping, and gradually moving the limb during the relaxation obtained. Dr. Blegborough, in these local diseases, has contrived a receptacle for the part from which the air is exhausted while the vapour is applied; but this seems unnecessary. If the vapour is confined, all the benefit will be obtained without previous exhaustion; or, in reality, the vapour itself, by rarefying the air, will exhaust the vessel sufficiently.

The warm bath, if the temperature is too high, will certainly be injurious to the plethoric, or those disposed to any accumulations in particular parts, unless they are such as the bath may dissipate. In the weak, the relaxed, and the irritable, it is hurtful; and hence the indiscriminate use of pediluvium in chlorosis and amenorrhœa has been highly injurious. In both views it is injurious in hectic fevers, and in scirrhusites of the liver. Hoffman thinks it hurtful in asthma; and it will be seemingly so from its effect on the respiration. Dr. Falconer differs from him in this respect; and, on trial, in convulsive asthma, it has not seemed particularly injurious, though so much benefit was not derived from it as to induce a repetition. Those subject to hæmorrhage should be cautious in its use; and, in general, danger may attend its employment after any agitation of mind or body, which greatly quickens the circulation. The Romans used it in the time of the emperors after a full meal: the practice is reprobated by Juvenal and Horace, rather as a luxurious than a dangerous indulgence.

After the bathing, sweating between flannels is generally enjoined; but if we wish to employ it as a stimulant, a copious perspiration should not be too freely indulged. The contracted vessels should be excited to action, but their powers should not be exhausted.

FOMENTATIONS and EMBROCATIONS are partial warm baths, and supposed to derive some virtue from their impregnations; but, in general, the heat and moisture, when the latter are used warm, are the most beneficial agents.

Warm baths, *impregnated with different medicinal substances*, are said to derive, from these, peculiar advantages. The baths at Bath and at Harrowgate, we shall on a future occasion notice; and we must here speak only of those imitations which are within our reach. We know of no instance in which the waters of Bath have been imitated for external use. Those of Harrowgate have been prepared by adding sulphurated

kali to water, in the proportion of two ounces to a sufficient quantity of fluid for a bath. They are chiefly used in cutaneous complaints, but we have had no experience of their efficacy.

An impregnation of warm water, though not an artificial one, is employed in *warm sea water*. This bath is supposed to be a more active stimulant than common water, and to be more useful, not only in palsy, but from the absorption of its salts in scrofulous complaints. We have reason to think that its powers are considerable; and it may be used at a low temperature in constitutions that cannot bear the shock of cold immersion, and in weak habits as a good preparative for sea bathing. The greater weight and pressure of salt water have been supposed to render it more useful as a bath, than fresh. It certainly is so; though, during the short immersion, we cannot easily perceive how any advantage can arise from its weight. In pumping, or pouring from a height, the momentum is certainly greater, and the advantages are proportionally increased.

Near smelting huts, it is not uncommon to impregnate baths with the scorix of iron, and sometimes with the mixed slag of copper, cobalt, &c. The slags and scorix are immersed in water while hot, or heated again for the purpose; and the baths thus prepared are supposed to be peculiarly useful as tonics. With a similar view, it has sometimes been a practice of boiling alum and quick lime together for a bath.

Scheutzer describes the pepper water of the Alps, which was formerly highly esteemed as a bath. It breaks out in a place almost inaccessible with great impetuosity in the spring, and continues till near October. The water, however, according to this author, contains no particular mineral.

THE VAPOUR BATH conveys heat less speedily than water, but a greater heat can be borne, and for a longer period. This, in reality, was the warm bath of the Romans, as it is of the Swedes, Russians, and the native Americans; and it is probably more efficacious both as a relaxant and a stimulant. It is certain, that water in a vesicular state is more powerful in its hygro-metrical affinity than when fluid; and Saussure, when he fixed the extreme point of moisture in his hygrometers in water, found that the index, in a fog, passed beyond it. This was our meaning when we remarked that man could live in air *beyond* the point of extreme humidity.

A bath of a different kind is that of *warm sand or earth*. The former is used by sailors in scurvy; the latter, we believe, has only been employed by quacks. We remember attending some experiments of this kind. A glowing heat was felt in the parts surrounded by the earth, but we remarked no peculiar change in the countenance that would lead us to suppose it a powerful remedy, and certainly no disease was relieved by it. The complaints to which it is apparently best adapted are cutaneous. See Edinb. Med. Comment. Decad. 2d vol. x. p. 153; also among the ancients, Hippocrates, Celsus, Cœlius Aurelianus, Aretæus, and Trallian; and among the moderns, Sir John Floyer, Dr. Wainwright on Bathing, and particularly Hoffman.

BA'LEUM ARE'NÆ. BALNEUM SICCUM. THE SAND BATH.

Over the mouth of a common wind furnace place one end of an iron plate with a ledge round it, and under this plate the canal must run, by which the furnace communicates with its chimney; the plate must then be filled with sand or other dry matter for placing the medicines to be digested in. The heat from the fire will be different in different parts of the plate; and thus, as more or less warmth is required, different situations are chosen.

The vessel containing the matter to be heated hath its bottom and sides totally covered with the sand, and there it is continued until the digestion is completed.

Ashes may be used in this bath when a less heat is wanted, sand for a greater, and iron filing for the greatest. See FURNAX.

**BALNEUM MARIS, vel MARIS.** The SEA WATER BATH; which admits of greater heat than boiling water, though sometimes it implies this only. In this bath, water supplies the place of sand; and when a greater heat than that of boiling water is not required, this method of digestion is preferable to that by the sand bath, because the heat cannot exceed at any time that which is required.

**BALNEUM SICUM.** See **BALNEUM ARENÆ.**

**BALNEUM VAPO' RIS.** A VAPOUR BATH. This is, properly, when the vessel containing the matter to be digested is exposed only to the steam that arises from boiling water.

**BALSAMA'TIO,** (from *balsamum, balsam*,) because balsams were used in that operation. The **EMBALMING OF DEAD BODIES.**

**BALSA'MEA,** (from the same). See **ABIES.**

**BALSAMELÆ'ON,** (from *βαλταμων, balsam*, and *ελαιον, oil*). See **BALSAMUM.**

**BALSAME'LLA,** (from the same). See **MOMORDICA.**

**BALSAMIO'LEUM.** See **BALSAMUM.**

**BALSA'MICA,** (from *βαλταμων, balsam*). **BALSAMICS,** or those medicines by which wounds are healed. The term includes medicines of very different qualities, as emollients, detergents, restoratives, &c. But all medicines of this kind are supposed to be soft, yielding, and adhesive. Balsamics are generally directed for complaints whose seat is in the viscera; and as they cannot be conveyed there but by the common road of the circulation, it follows that no effects can be expected from them but by their long continuance. Hoffman calls those medicines by the name of *balsamics* which are hot and acrid; and unites with them the natural balsams, and gums, by which the vital heat is increased. Dr. Cullen considers almost all of the substances called **BALSAMS** to have the form and consistence of turpentine, and in general to possess similar virtues; see **TEREBINTHINA.** Dr. Fothergill seems to be of the opinion of Hoffman, and cautions against their use in ulcers of the lungs. Though modern chemists are not agreed as to the difference between balsams and resins, still balsams are considered to be fluid, odorous, inflammable substances, and contain a concrete acid, which may be obtained by sublimation or decoction. Balsams probably contain the largest proportion of oil, and resin of oxygen. See *Med. Observ.* vol. iv. p. 231—18. Cullen's *Materia Medica.* Lewis's *Materia Medica.*

**BALSAMI'FERA,** and **A'RBOR I'NDICA,** (from *βαλταμων*, and *φερω, fero, to bear*). See **PERUVIANUM BALSAMUM.**

**BALSAMI'FERA A'RBOR BRASILIE'NSIS.** See **CAPIVI BALSAMUM.**

**BALSAMI'NA,** the balsam apple, (from *balsamum*,) so called from its odour. See **MOMORDICA.**

**BALSAMI'NA LUTE'A.** See **PERSICARIA SILIQUOSA.**

**BALSAMI'TA MINOR,** (from *balsamum*). See **AGERATUM.**

**BA'LSAMUM,** (from the Hebrew terms *baal samum, the prince of oils*,) called also *balsamum genuinum antiquorum, balsamelæon, Egyptiacum balsamum; bals. Gileadense, Asiaticum, Judaicum, è Mecchâ et Alpini; oleum balsami, xylobalsamum, opobalsamum*, the **BALM OF GILEAD**; a resinous juice, obtained from an evergreen tree, or shrub, of Arabia. The finest is of a greenish colour, and obtained by incision of the branches, called *opobalsamum*. The second is called *carfiobalsamum*, expressed from the fruit, which is about the size of a small pea with a short pedicle, of a roundish or oval figure, pointed at the top, composed of a dark brown or reddish black, wrinkled bark, marked with four ribs from top to bottom, and a whitish or yellowish medullary substance. This fruit, when in perfection, is said to have a pleasant, warm, bitterish taste, and a fragrant smell, resembling that of the balsam itself; but such as we now meet with in the shops is almost without smell or taste. It was only ordered in the *Theriaca Andromachi*, and *Mithridate*, for which, by the London college, cubebs were substituted; though now both these compositions are properly rejected. The third sort is reddish, called *xylobalsamum*, and obtained from a decoction of the branches, (Bruce). The plant was supposed to be the *amyris Gileadensis* and *opobalsamum* Lin. Willdenow, vol. ii. p. 334. Gledisch has formed a new genus of the *a. opobalsamum*, which he styles *balsamea Meccanensis*. It is a variety of the *a. opobalsamum*, which is scarcely distinct as a species from the *a. Gileadensis*. The first sort, which naturally exudes from the plant, is scarcely known in Europe. Prosper Alpinus says, that it is at first turbid and whitish, of a strong pungent smell like that of turpentine, but much sweeter and more fragrant, of a bitter acrid astringent taste; on being kept it becomes thin, limpid, light, greenish, and then of a golden yellow; after which it is thick like turpentine, and loses much of its fragrance. Its smell resembles that of citrons, or rather a mixture of rosemary and sage flowers.

All the balsams agree in their general qualities, differing only in the degrees of warmth, fragrance, pungency, and gratefulness. The balm of Gilead is a warm stimulant, and supposed to be a cordial diuretic; but the latter quality is greatly increased by the addition of a fixed alkaline salt. It is supposed to be also an expectorant, which it may be in a slight degree; but its chief use in the East is as a cosmetic. See Lady Mary Wortley Montague's Letters.

The balm of Gilead is generally used in medicine as a cordial; and, from its stimulus, is supposed to restrain mucous discharges from the vagina and urethra. In tabes it has been commended; but, like the turpentine, is probably too stimulant.

The Canadian balm of Gilcad fir affords a balsam that

is often imposed for the genuine sort. If the true balsam is dropped in water when thin, it spreads itself on the surface, imparting to the water much of its taste and smell; and the grosser part, remaining at the top, is thick enough to be taken up with a needle; this is reckoned a mark of its being genuine. If pure balsam is dropped on a woollen cloth, it may be washed off without leaving the least stain or mark, but the adulterated kind sticks to the place. The pure coagulates with milk, but the adulterated will not. The dose is from fifteen to fifty drops.

BA'LSAMUM TRAUMA'TICUM. See BENZOINUM.

BA'LSAMUM GU'DONIS. See ANODYNUM BALSAMUM.

BA'LSAMUM GENUINUM ANTIQUORUM. See BALSAMUM.

BA'LSAMUM ARCÆI. See ELEM.

BA'LSAMUM ARTHRITICUM is the acid of vitriol sheathed with olive oil, in the proportion of four to one.

BALSAMUM CANADENSE. We have already remarked, that balsams, in the strictest sense of the term, are turpentine of different odours and flavours, as combined with different essential oils. The present balsam is a striking instance of this resemblance, as it differs little from the turpentine, and is produced from the *pinus balsamea* and *Canadensis* Lin. Sp. Pl. 1421.

BALSAMUM CARPATHICUM is produced from the *pinus cembra* Lin. Sp. Pl. 1419, which grows on the Carpathian mountains in the Tyrol, and different parts of Germany. It is called *balsamum libani*; and the oil distilled from it, *ol. templinum*, and by the Germans *kruhmholzel*. It differs little from the turpentine.

All these natural balsams, with those to be afterwards described, agree in being natural compounds of an oily and a resinous substance, with an acid principle. Their first use seems to have been external; and in wounds, with the gluten of the blood, they formed a coagulum, which checked the bleeding, and preserved the injured part from the air. They in time became favourite remedies in internal bleedings, but their irritation is found to be injurious, and in such cases balsams are no longer trusted.

BALSAMUM COPAIBÆ is obtained by incision of the trunk of the *copaifera officinalis* Lin. Sp. Pl. 557. It is colourless when first obtained, but becomes yellow by time, without losing its transparency. The smell is fragrant; the taste aromatic, bitter, and somewhat sharp, very permanent on the tongue. It affects with some acrimony the urinary organs, and is said to render the urine bitter. It unites with fixed and volatile oils, and with spirit of wine. By distillation in water we separate the oil from the resin; and, in the former, the taste and smell of the balsam are concentrated: if the operation is carefully performed, about one half of the balsam rises into the receiver, in the form of oil.

It is given in all the diseases of the urinary organs when no inflammation is present. In gleet and in leucorrhœa it is often employed; in gonorrhœa it was once a favourite remedy, but is now disused. In diseases of the kidneys it is still employed, though less frequently than usual; and, in hæmorrhoids it is occasionally trusted. The dose is from thirty to sixty drops, mixed with water by means of an egg. The balsam *copaibæ* is occasionally adulterated with turpentine, but its virtue is not greatly impaired by the fraud.

BALSAMUM LOCATELLI. This preparation, now disused, consisted of two parts of oil with one of wax, coloured with dragon's blood or red sanders. In some formulæ balsam of Peru was added. It was used as an expectorant.

BALSAMUM PERUVIANUM, from its country Peru; BALSAM OF PERU, *Putzochill*, *Indian*, *Mexican*, and *American balsam*, and *Carbareiba*, the name of the tree from which, according to Piso and Ray, it is taken. It is the *myroxylon peruiferum* Lin. Sp. Pl. Wildenow, vol. ii. p. 526. Nat. order *leguminosa*. The native balsam which naturally exudes is white; but this we never meet with. The native balsam inspissated is the white styrax, or the dry balsam of commerce. It is of a reddish colour, less hot and more fragrant than that usually in the shops. What is commonly sold is the black or dark red balsam, which is a decoction of the branches inspissated. Its smell is highly fragrant; its taste warm, bitterish, and acrid, very permanent on the back part of the tongue. It does not mix with water, but by long agitation imparts to it a fragrant smell and some of the properties of the balsam. It dissolves readily in spirit of wine, and is decomposed by fixed oils, which unite with the essential oil and acid, leaving a resin. It does not unite with other balsams. Distilled with water it gives about one-sixteenth of a reddish essential oil, with difficulty dissolved in water: distilled *per se* this oil is empyreumatic; with a moderate, cautiously regulated heat, a small proportion of benzoic acid may be separated from it. Baumé supposes that it is adulterated by the second oil which arises from benzoin, digested on poplar buds. This is not very probable, but no very injurious fraud. The dose is from five to twenty drops, suspended in water by the mucilage of gum arabic.

Internally it is a warm stimulant and tonic, useful in dyspepsia, in atonic gout, in mucous discharges, amenorrhœa, and humoral asthmas. Where the bronchial glands are greatly relaxed, it is useful even though the lungs are ulcerated, given in small doses. It is best exhibited in pills with aloes and aromatics, when used as a corroborant, and in a saline draught in hectic.

Externally it is an useful application to relaxed ulcers not disposed to heal.

BALSAMUM RAKASIRÆ resembles the Tolu balsam, and is brought from India, but its source we are ignorant of, and some have supposed it to be a composition. In its qualities it resembles the Tolu balsam.

BALSAMUM SULPHURIS is a very fetid, stimulating balsam, prepared by uniting sulphur with a large proportion, sometimes eight times its weight, of olive oil. It was usually given in hectic cases, but now no longer employed. When there has been a considerable relaxation of the glands, and the expectoration stopped from debility, we think that we have seen it of service. It is sometimes made with petroleum instead of olive oil, and is then most offensive, and probably injurious.

BALSAMUM SULPHURIS TEREBINTHINATUM and ANISATUM are made by digesting the sulphur with oil of turpentine, and in the latter adding the oil of aniseed. They are now confined to veterinary medicine.

BALSAMUM TOLUTANUM is obtained by incision. The tree is a native of Carthage; *toluifera* bal-

*samum* Lin. Sp. Pl. 549. It is of a reddish yellow, transparent and tenacious, but from age brittle. The smell is fragrant, the taste slightly warm and aromatic. It consists of oily, with a slight proportion of resinous particles, united with a large one of benzoic acid, and is from hence partly soluble in watery liquids, though it is wholly dissolved in spirit of wine. The watery solution is the basis of the old *syrupus balsamicus*, now *syrupus toltanus*; and, in spirit, it forms the *tinctura balsami toltani*. It is little employed in medicine, though it is at least a safe, if not an effectual, expectorant. In gleets it is sometimes useful, and has been applied to wounds and ulcers, when a slight stimulus was required.

**BALSAMUM VITÆ**, *beaume de vie*, consisted of a great variety of the warmest and most grateful essential oils, with balsam of Peru, dissolved in highly rectified spirit of wine; but it is now greatly abridged in the number of ingredients, and little used.

**BAMBA'LIO**, (from *βαμβαιω*, to stammer). A man that stammers or lisps.

**BA'MBAX**. See **BOMBAX**.

**BA'MIA MOSCHA'TA**. See **ABELMOSCH**.

**BAMMA**, (from *βαπλω*, to emerge). See **EMBAMMA**.

**BANA'NA**, **BANANIE'RA**, (Indian). Called also *ficoides*, or *figus Indica*, *musa fructu cucumerino breviori*, *senoria*, *jacaira*, and the **BANANA** OR **PLANTAIN TREE**. It is the *musa sapientum* Lin. Sp. Pl. 1477. The parent tree of all the American bananas, is the *m. bihai*. Nat. order *scitamineæ*. It grows in America; its fruit is diuretic, heating, and highly nutritious.

**BANDAGE**. See **DELIGATIO** and **FASCIA**.

**BANDU'RA**; called also *planta mirabilis distillatoria*; *utricaria*; *priapus vegetabilis*; *Nepenthes*. It is the *Nepenthes distillatoria* Lin. Sp. Pl. 1354. It is a plant which grows in the thick forests of the island of Ceylon, where its long fibres supply it with water, and where no sun comes to exhale it. Its seeds and seed vessels are like those of gentian; but it is most remarkable for a foliaceous sheath about a foot long and as thick as a man's arm; and for its appendages at the ends of its leaves, which turn up, and contain a cooling limpid liquor, as does its sheath, which is half full and potable. The root is astringent; the liquor in the sheath is cooling; it grows not far from Columbo, in moist shady woods. Raii Hist.

**BANGU'E**, (Indian). *Cannabis Indica* Lin. *cansjava*, called by the Egyptians *assis*; *asserac cannabis peregrina*, *althea foliis cannabinis*, *kalengi-cansjava*, *tsyeru-cansjava*.

It resembles hemp in its stalk, the rind of the stalk, and the leaves; but its medicinal qualities differ very much. The seeds and leaves are heating and intoxicating. When in pain the Hindoos mix it with opium: when their object is mirth and intoxication, with musk, amber, and sugar. It grows in Indostan, and other parts of the East Indies.

**BA'NICA**. See **PASTINACA SILVESTRIS**.

**BANILIA**, **BANILAS**. See **VANILLA**.

**BANKSIA**. *B. Abyssinica* Bruce. The flowers are chiefly employed for ascarides in Abyssinia. A handful is infused in two quarts of beer. It is not the same plant with the banksia of the Supplementum Plantarum, and has not yet found a place in botanical systems.

**BAO'BAB**, **BAHOBAB**. It is the *adansonia baho-*

*bab* Lin. Sp. Pl. 960, of the natural order *malvaceæ*. The tree is the largest production of the whole vegetable kingdom. The trunk is not above twelve or fifteen feet high, but from sixty to eighty-five feet round. The lowest branches extend almost horizontally; and as they are about sixty feet in length, their own weight bends their extremities to the ground, and thus they form an hemispherical mass of verdure about one hundred and twenty, or one hundred and thirty feet in diameter. The centre root penetrates far into the earth; the rest spread near the surface.

The flowers are in proportion to the size of the tree; and are followed by an oblong fruit pointed at both ends, about ten inches long, five or six broad, covered with a kind of greenish down, under which is a rind, hard, and almost black, marked with rays which divide it lengthways into sides. This fruit hangs to the tree by a pedicle two feet long and an inch in diameter. It contains a whitish spongy juicy substance of an acid taste, and seeds of a brown colour and the shape of a kidney-bean, which are called *goui*. The pulp that surrounds these seeds is powdered when dry, and brought into Europe from the Levant, under the name of *terra sigillata Lemnia*. It grows on the west coast of Africa, from the Niger to the kingdom of Belin.

The kernel of the fruit contains a large proportion of alkali when burnt, and the negroes mix it with palm oil to make soap.

The bark of this tree is called *lalo*; the negroes dry it in the shade, then powder and keep it in little cotton bags, and put two or three pinches into their food; it is mucilaginous, and powerfully prevents too violent perspiration.

The mucilage obtained from this bark is a powerful remedy against the epidemic fevers of the country that produces these trees; so is a decoction of the dried leaves. The fresh fruit is as useful as the leaves for the same purposes.

**BA'PTES**, a fossil medicinal substance, now unknown; probably a bitumen.

**BA'PTICA CO'CCA**. See **CHERMES**.

**BA'RAMETZ**, and **BA'ROMETZ**, a plant somewhat resembling the shape of a lamb. See **AGNUS SCYTHICUS**.

**BA'RAS**. (Arabic). See **ALPHUS**.

**BA'RBA**, a **BEARD**. Some vegetables have the specific term of *barba* given them, as their ramifications are bushy like a beard; viz.

**BA'RBA ARO'NIS**. See **ARUM**.

**BA'RBA CAPRINA**. See **SPIRÆA ULMARIA**.

**BA'RBA HIRCI**. See **TRAGOPOGON**.

**BA'RBA JOVIS**. See **SEDUM**.

**BARBADO'ES TAR**. See **PETROLEUM BARBADOENSE**.

**BARBADO'ES CHE'RRY**, the fruit of the *malphigia glabra* Lin. Sp. Pl. 609, resembling the inferior of our cherries.

**BARBAREA**. *Herba sanctæ Barbaræ*, *nasturtium hybernum*, *pseudobunias*, *cruca lutea latifolia*, *sisymbrium*, *carphitaria*, *winter cresses*, *garden rocket*, *rocket gentle*, *erysimum barbarea* Lin. Sp. Pl. 922. This plant resembles the mustard, but is distinguished by the smoothness of its leaves and its disagreeable smell. It resembles in quality the cresses, and is a native of Switzerland, but cultivated in our gardens.

The WILD ROCKET, called *eruca silvestris*, *sinapis alba* Lin. It grows on old walls and amongst rubbish. Its qualities are much the same as the former, but its taste is somewhat more acrid and bitter.

The active matter of the leaves is extracted by expression; by infusion in boiling water; and by digestion in rectified spirit. By distillation in water, a pungent yellow oil is obtained; by drying, the disagreeable smell and pungency are destroyed. The pungency of the seeds is less volatile, similar to, though weaker than those of mustard.

BARBA'RIA, BARBA'RICUM, (from *barbarus*, wild; because it was brought from a wild country). See RHABBARUM.

BARBAROS'SA PIL. BARBAROSSA'S PILL. It was composed of quicksilver, rhubarb, diagridium, musk, amber, &c. and was the first internal mercurial medicine which obtained any real credit. See ARGENTUM VIVUM.

BA'RBARUM. The name of a plaster in Scribonius Largus.

BARB'OTA. The BARBUT. A small river fish, with a very large head. It is generally about six inches long; it lives on mud and slime; is found in the river which runs from Tamworth, in Warwickshire. The roe, as well as that of the eel pout, operates both upwards and downwards.

BAREGE WATERS. This appellation is given to four springs near the foot of the Pyrenées on the side of France. Their heat is from 73° to 120°. They contain sulphurated hydrogen, united to a small proportion of soda and some sea salt. The water is however very pure, scarcely exceeding in specific gravity distilled water. It is chiefly useful externally from its heat, and in cutaneous diseases from its sulphureous impregnation. It is supposed to be useful in atony of the stomach and calculous complaints. See BALNEUM.

BARDA'NA. BURDOCK. *Arctium betonica Britannica*. By Myrepsus called *ilaphis*. It grows on highway sides, and is sufficiently known by the burs which stick to the clothes.

BARDA'NA MAJOR, called also *lappa major*, *personata arctium Dioscoridis*; CLOTBUR, or GREAT BURDOCK. It is the *arctium lappa* Lin. Sp. Pl. 1143. The roots have a little faint smell, but a sweetish taste, with a light austerity. Boiled in water, they impart a brownish colour, and a vapid taste. Extracts, however made, are as insipid as the root. They are chiefly commended as diuretic, diaphoretic, and antiscorbutic, and have been successfully employed in rheumatisms, the lues venerea, scurvy, gout, pulmonic complaints, and in all cases where China and sarsaparilla roots, which they resemble, are prescribed.

The leaves are bitter, and more saline than the roots, and have no sweetness. The seeds are extremely bitter, and very slightly aromatic. A drachm proves diuretic; but the prickly matter on their surface must be well removed before administering them. The best method of using this plant as a medicine is in the form of a decoction, in which two ounces of the roots are boiled in three pints of water to a quart; to this two drachms of vitriolated kali have been usually added. Of this decoction a pint should be taken every day in scorbutic and rheumatic complaints; and when intended as a diuretic, in a shorter period.

BARDA'NA MINOR, called also *lappa minor*, *xanthium, charadolethron*; by Etius, the LESSER BURDOCK, or LOUSE BUR. *Xanthium strumarium* Lin. Sp. Pl. 1400. From this roughness of the fruit it is called a *burdock*, though not in the least allied to that plant. It grows in rich fat soils, and is found on some commons. Its juice is commended against scrofulous disorders.

BARDA'NA ARCTICUM, called also *lappa major montana*, *personata altera*, *arctium*, and WOOLLY HEADED BURDOCK. Its virtues are much the same with the other species of *burdocks*, and it is a variety only of the *a. lappa*.

BARI'GLIA, BARI'LLA, so called from the place where it is produced. See ANATRON.

BARLEY. See HORDEUM.

BARLEY. (Indian). See VERBASCUM CEVADILLA.

BARNET WATER. It is of the purging kind, of a similar quality to that of Epsom, and about half its strength.

BARO'METRUM, BAROMETER, (of *βαρος*, weight, and *μετρον*, measure). An instrument to determine the weight of the air, or observe the changes of weather; it is commonly called a WEATHER GLASS, and frequently the Torricellian tube, from Torricelli its inventor.

The bore of the common tubes is too small. The glass tube should be one third, or at least one fourth of an inch in diameter, hermetically sealed at one end, and open at the other; the length should be thirty-four inches: the mercury with which it is filled must be pure. Fill the tube quite full with this mercury; and having in readiness a basin with a flat bottom, and about two inches high, in which is also some mercury, invert the tube, and put it in the basin, still holding your finger underneath it till it is in the mercury of the basin, then place it in a frame. On taking away your finger, the mercury in the tube will immediately subside to about twenty-nine or thirty inches, according to the state of the air, it being very rarely lower than twenty-eight, or higher than thirty inches, when the air is heavy. If a scale of four inches be divided into tenths, and placed against the upper end of the tube, the instrument is complete, and equal to every change. The mercury, however, still contains some air entangled with it, which will in time rise to the upper part of the tube, and not only by its pressure prevent the rising of the mercury, but by its expansion, from a change of temperature, produce many irregularities in the motion of the quicksilver. The tube may be previously cleaned by a wire, to the end of which a bit of leather is attached, and this will lessen the quantity of entangled air; but, to render the instrument perfect, the mercury must be boiled in the tube. We once separated in this manner more than an inch of air.

The *barometer* measures the weight of the air with sufficient exactness for the general purposes of life, yet it is affected with many irregularities, that no exactness in the instrument can remedy, and no theory explain. Many of these irregularities can be however explained, by considering the mercury as suspended, not only by the weight of the air, but in part by its elasticity. The barometer is, in reality, a MONOMETER. Moist air is very inelastic, the mercury of course falls; and the human body, from a diminution of the tone which pres-

sure gives, feels a languor. Dry air produces a contrary effect; and Saussure found, that water evaporating, produced a gas of very considerable elasticity. When high winds blow, the mercury is generally low; it rises higher in cold weather than in warm; and is usually higher in the morning and evening than at mid day: it generally descends lower after rain than it was before it.

On advancing up high mountains, the air is less and less dense, and usually the same inconveniences are felt that are complained of when the air is moist. But M. De Luc and his companions observed, when at the summit of the Buet, 3315 English yards above the level of the Mediterranean, no difference in the effects of the diminished density of the air, which was one third less than that of the plains below them. In this place, M. De Luc observes, 'how much naturalists are deceived in attributing the alterations that many persons experience, upon the falling of the *barometer*, to a difference either in the weight or density of the air. For if these changes, he says, could so sensibly affect our organs, what would become of those chamois hunters, who pass every day from the bottom of the vallies to the highest mountains? These people perceive no inconvenience; even asthmatic people find little, notwithstanding the *barometer* varies in these several places, as is usually observed in other similar ones.' If, however, our feelings are connected not only with the actual weight but the elasticity of the air, these difficulties will vanish; for the highly elastic gas which is produced by evaporating water, rises to the upper regions of the atmosphere, and compensates for the want of density. M. De Luc's reasoning, however, is very vague and inconclusive. Those accustomed to considerable changes of any kind, experience but little inconvenience from them; and other travellers have really found considerable languor on these very elevated spots.

The *barometer* may be applied to several uses, as measuring the heights of mountains: for twelve thousand and forty inches of air being equal to one inch of mercury near the surface of the earth, twelve hundred and four inches, or one hundred feet, must be equal to one tenth of an inch of mercury. Consequently, if a *barometer* be carried up any great eminence, the mercury will descend one tenth of an inch for every hundred feet that the *barometer* ascends. This we do not mean as a correct view of the subject, for many circumstances must be attended to in the actual measurement of heights, particularly the temperature. To consider all the necessary corrections is not a part of our subject. See *De Luc*, *Saussure*, *Trembley*, and *Sir G. Shuckburgh's* papers in the *Philosophical Transactions*.

But the great use of the *barometer* is to predict the future state of the weather for several hours, and sometimes days preceding, in many instances to a degree of probability. 1st, The rising of the mercury presages fair weather, and its falling, wet. 2d, In very hot weather, the sudden falling of the mercury foretels thunder. 3d, In winter, its rising portends frost; and in a continued frost, foretels snow. 4th, When foul weather happens soon after the falling of the mercury, it will soon again change, and so on the contrary. 5th, When the mercury continues to rise for some time before the foul weather is over, expect a continuance of fair weather to follow. 6th, In fair weather, when the mercury continues to fall before rains come, then ex-

pect a great deal of it, and probably high winds. 7th, The unsettled motion of the mercury denotes changeable weather.

It is not so much the height of the mercury that indicates the weather, as its motion up and down; therefore, to know whether the mercury is actually rising or falling, observe whether the surface of the mercury be convex, for it is then rising: if the surface be concave, it is falling: if the surface be plain, or a little convex, it may be considered as stationary.

There are different forms of this instrument which have each their advantages and disadvantages: but the common sort is perhaps better than any other if carefully constructed.

BARO'NES. Small worms; called also *nephones*.

BA'ROS. (Greek). GRAVITY. Hippocrates uses this word to express by it an uneasy weight in any part.

BA'ROS. See CAMPHORA.

BARTHOLINIA'NÆ GLANDU'LÆ, (from the discoverer Bartholine). See SUBLINGUALES GLANDULÆ.

BARYOCO'CCALON, (from *βαρυς*, *grave*, and *κοκκαλος*, *a nut*; so called because it gives a deep sound). See STRAMONIUM.

BARYPHO'NIA, (from *βαρυς*, *dull*, and *φωνη*, *the voice*). A difficulty of speaking.

BARYPI'CRON, (from *βαρυς*, *dull*, and *πικρον*, *bitter*). See ABSINTHIUM VULGARE.

BARY'TES, (from *βαρυς*, *heavy*,) called, from its weight, also *terra ponderosa*, PONDEROUS EARTH.

This is not found very abundantly, or in large continued masses, but chiefly in the vicinity of mines, or veins of metal. Its species are aerated and vitriolated ponderous earth, either in the form of a transparent spar, or an opaque earth, of a white grey, or fawn colour; frequently of no regular figure, but often in the peculiar form of a number of small convex lenses, set edgewise in the ground. We are indebted to the celebrated chemists, Gahn, Scheele, and Bergman, for our more particular knowledge of this earth; but the vitriolated barytes was mentioned so early as 1700, by Legh, in his *Natural History of Lancashire, Cheshire, &c.*

As this has seldom been found pure, in order to obtain it in a suitable degree of purity, we are favoured with the following process by M. I. A. Chaptal. The sulphate of barytes, or the vitriolated ponderous earth, which is its most usual combination, is pulverised and calcined in a crucible, with an eighth part of powder of charcoal: the crucible must be kept ignited during an hour; after which the calcined matter is to be thrown into water. It communicates a yellow colour to the fluid, and at the same time a strong smell of hepatic gas is perceived; the water is then to be filtered, and muriatic acid poured in; a considerable precipitate falls down, which must be separated from the fluid by filtration. The water which passes through the filter holds the muriatic barytes in solution. The carbonate of potash, or mild vegetable alkali, in solution, being then added, the ponderous earth falls down; and the carbonic acid may be driven off by calcination. The product saturated with the muriatic acid, and little more of the acid being afterwards added, supplies the *terra ponderosa muriata*, or *salita*, which is considered as an evacuant, deobstruent, and tonic. It is given in solution, and half a drachm is dissolved in an ounce of water. On exhibition, it has been found in small doses to in-

crease the flow of urine, promote perspiration, open the bowels, and improve the appetite and general health. It has been considered as highly useful in scrofulous cases, chronic cutaneous complaints, and ulcerated legs. In some cancers, infarcted mesenteric glands, scirrhus testicle, buboes, asthma, and ascarides, it is said to be of advantage. Its dose is from six to ten or twenty drops; but if ever it occasion vertigo, nausea, purging, or pains in the bowels, the dose must be reduced, or the medicine omitted. Small doses, gradually increased, may be given twice a day, so long as they create no inconveniences. This medicine is however suspicious; and the vitriolated barytes is known to be poisonous. As the muriatic acid is but weakly retained, many substances may separate it. Even fixed air will decompose it; and in its exhibition hard water, alkaline, earthy, and metallic salts, particularly tartar emetic, should be avoided. Its irritating quality is so great, that it has produced considerable inconvenience in the more irritable constitutions and in spasmodic complaints. In scrofula, in some cutaneous diseases, and in indurated scirrhus tumours, we have found it successful; and when we have failed, have had reason to attribute the failure to the imperfect state of the medicine. Its purity may be ascertained by a little Glauber salt, or any vitriolated neutral. The smallest atom will occasion an evidently conspicuous deposition. Barytes acts on vegetable and animal substances, dissolving muscular fibres, and forming insoluble soaps with oil. For a further account see Med. Commentaries, vol. iv. and vi. dec. 2; Medical Communic. London, vol. ii. Chap-tal's, Gren's, and Thompson's Chemistry.

**BASA'AL.** (Indian). The name of an Indian tree growing about Cochin. It flowers and bears fruit once every year, from the first year of its bearing to the fifteenth. A decoction of its leaves with ginger in water is used as a gargle in disorders of the fauces. The kernels of the fruit kill worms. Raii Hist.

**BASANITES.** A close grained stone resembling a lava, said by Pliny to contain a bloody juice, and useful in diseases of the liver. See **BASILICUM**.

**BASILARE,** (from βασιλεως, a king). This is used as a term of superior excellence or magnitude when applied to bones. See **CUNEIFORME**, **SPHENOIDES**, and **SACRUM OS**.

**BASILARIS ARTERIA.** It is a branch of the vertebral artery upon the apophysis *basilaris* of the os occipitis. The two vertebral arteries soon unite after they have entered the skull, and form this artery about the cuneiform process of the os occipitis. It runs forward under the great transverse protuberance of the medulla oblongata, to which it gives ramifications, as well as to the neighbouring parts of the medulla. Sometimes it divides into two branches near the apophysis *basilaris*, which communicate with the posterior branches of the two internal carotids, and are lost in the posterior lobe of the brain.

**BASILEION.** An epithet for a collyrium in Ætius.

**BASILARIS APO'PHYSIS.** The great apophysis of the os occipitis.

**BASILICA.** Black-seeded. See **AGROM**.

**BASILICA VE'NA.** The ancients termed the basilic vein of the right arm the *vein* of the liver, **HEPATICA BRACHII VENA**: and that of the left arm, the *vein* of the spleen, **SPLENICA VENA BRACHII**. Sometimes the

basilica hath a double origin, by a branch of the communication with the trunk of the axillaris. It continues its course along the middle of the os humeri, between the muscles and integuments; and having reached the inner condyle, and sent off obliquely in the fold of the arm the *mediana basilica*, it runs along the ulna, between the integuments and muscles, a little towards the outside, by the name of *cubitalis externa*; and, a little below it, sends off another branch, which runs along the inside of the fore arm near the ulna: this branch may be called *cubitalis interna*. See **CEPHALICA VENA**.

**BASILICUM UNGU'ENTUM FLAVUM.** UNGU'ENTUM RESINÆ FLAVÆ. OINTMENT OF YELLOW RESIN, consists of a pint of olive oil, yellow wax, yellow resin, of each a pound. To the wax and resin melted over a gentle fire the oil is added, and the mixture strained while hot.

It is commonly employed as a digestive on wounds and ulcers; and is as useful as the linim. Arcæi, now called unguent. è gummi elemi. If required to be a little warmer, a few drops of ol. terebinthinæ com. may be added when used. It justly supersedes the use of every similar application.

**BASILICUM,** (from βασιλικος, royal, so called from its great virtues). **BASIL**; called also *acinos*, *ocymum vulgare*, *herba regia*, *ocymum medium*, *citratum*. COMMON, or CITRON BASIL. *Ocymum basilicum* Lin. Sp. Pl. 833.

*Ocymum caryophyllatum*, *ocymum minimum*, (from οκυς, swift,) so called because of its swift growth. SMALL, or BUSH BASIL, with uncut leaves. *O. b. minimum* Lin. Sp. Pl. 833. Nat. order *labiatæ*.

Both these are natives of the eastern countries, and sown annually in our gardens for culinary uses. The seeds, which rarely come to perfection in England, are brought from the south of France and Italy. They flower in June and July, and produce seed in August.

Infusions of the leaves are drunk in catarrhal complaints, uterine and pulmonic diseases. They are succulent, slightly aromatic, have a mucilaginous taste, and strong smell, which they lose partly in drying. The first sort resembles the scent of lemons; the second that of cloves. Distilled in water they yield much oil of a penetrating fragrance, similar, but superior to the oil of marjoram.

*Clinopodium majus*, (from κλινε, a bed, and πος, a foot,) so called because its leaves are like the foot of a bed. Called also *clinopodium acinos* Lin. Sp. Pl. 826, GREAT, WILD, and STONE BASIL; a species of thyme. It grows in hedges; is supposed to be an astringent and emmenagogue.

**BASILICUS PULVIS,** (from βασιλικος, royal, a king). THE ROYAL POWDER.

This term has been applied to various purging powders, which contain cream of tartar as one of the ingredients. The term was afterwards changed to *pulvis laxans*, and it was then cream of tartar with an equal part of senna. A small proportion of scammony is now added, and the appellation is the *pulvis è senna compositus*. It is an useful and convenient purgative, though with senna alone not sufficiently active. The following simple purgatives are observed to be both more agreeable and more useful.

“R. Calomel, pp. ʒ ij. pulv. rhab. ʒ ss. jalap. ʒ x. m.  
“Or, R. Antimonii tartarisati, gr. iv. calom. ʒ i. gr. iv. jalap. ʒ ss. gr. viij. m.

"This is a convenient purge for gouty and rheumatic people, for whom it is best made into pills, and to be taken at bed time. It is also one of the best purges for gross bodied children, who are subject to head worms and have large bellies; for though the ingredients are efficacious, its operation will be mild and safe enough. It clears the bowels of slime, and discharges those humours that obstruct the mesenteric glands, and in a great measure the lacteals themselves, which is often the case in children; and is attended with a hard belly, a stinking breath, frequent fevers, and a decay of strength in the lower parts. Those slight intermittents, which such children are subject to, will much sooner be cured by such a purge than by the bark; for these purges reach, and carry off the cause, but the bark pens it up; and by curing one, while such restriction continues, gives room for a return with much greater aggravation. The dose for children is from ten grains to fifteen; for adults from fifteen grains to two scruples." MOTHERBY.

BASILIDION. A cerate described by Galen, and used for the itch.

BA'SILIS. A collyrium mentioned by Galen.

BASIOGLOSSUS, (from *βασίς*, the foundation, and *γλῶσσα*, the tongue). A muscle so called from its insertion. See HYOGLOSSUS.

BASIO-PHARYNGÆI, (from *βασίς*, foundation, and *φαρυγξ*, the fauces). A muscle so called from its position. See HYOPHARYNGÆUS.

BA'SIS, (from *βαίνω*, I am fixed). The support of any thing upon which it stands.

The broad part of the heart is called its *basis*, to distinguish it from the apex or point.

In pharmacy by basis is meant that ingredient on which the most stress is laid for answering the intention of any compound medicine.

BASSI COLICA. The name of a medicine in Scribonius Largus, compounded of aromatics and honey.

BATEA'NEA ALUMINO'SA A'QUA, (from the inventor Bates). See ALUMEN.

BATHING, COLD and SEA.

By the cold bath is meant that application of cold water which produces a sense of coldness called a *shock*, and which is followed by the increased action of the extreme vessels styled a *glow*. One extreme of the scale we well know, that of the freezing point; the other is undetermined. The Buxton water of 82° occasions a slight but sensible shock, so that the limits are not below this degree; and as temperate heat is placed at 62°, we shall not be greatly in error if we fix the other extreme at 72°.

The first effects of the cold bath are well known. The whole body is contracted; the bulbs of the hair are conspicuous; and the skin, resembling that of a newly plucked goose, has been styled *cutis anserina*. The debility and tremor are considerable; a sense of weight is felt in the head; the respiration is quick and laborious. These appearances are followed by a very different series. A glow soon returns to the surface; the weight in the head is almost instantaneously relieved, and every function appears to be carried on with increased activity. If a person stays for a longer period in the cold bath, the glow will be slighter and soon disappear, while every previous symptom of debility will return and continue.

Few experiments have been made on the effect of the pulse after cold bathing. Dr. Stock has, in the trials he made, found in general the pulse quicker and weaker after immersion; in a few instances only slower. The writer of this article has found similar results; but the pulse, felt at a more distant period than that mentioned by Dr. Stock, has been usually more slow and full. In a slight feverish complaint, the quickness of the pulse was greatly mitigated. Other authors have found the pulse much slower, but this was the consequence of partial cold only.

If the immersions are at due intervals repeated, and the stay in the bath be not improperly continued, the general health and spirits are greatly improved; the different necessary evacuations properly carried on and supported; and the body and mind appear to act with increased vigour.

The explanation of these phenomena is not difficult. The cold, by its sedative power, represses the circulation in the extreme vessels, and the fluids are accumulated in the larger arteries and veins. Whether the distention excites the action of the former; whether in consequence of repressed irritability it is afterwards restored with greater vigour; or whether the vires medicatrices *re-act* to conquer debility; we must not now enquire: but in every such circumstance, from one of these causes, the circulation is again restored with additional activity. The repetition of cold bathing produces tonic effects, which, we own, that we are inclined to attribute to the frequent exertion of this reacting power. We have often remarked in this work that the constitution gains energy by the exertion of those powers which preserve life and correct deviations, and we think the benefit, thus obtained, is a proof of that position.

According to the management of this remedy, we may therefore secure very different and opposite effects. A sudden change in the determination of the blood and nervous power, assisting its re-action, will produce a very different effect from the *continued*, and this again from the *repeated*, application: a distinction necessary to be attended to, in considering the different diseases in which the application of cold water has been considered as a remedy.

From the sudden changes in the determination of the blood it has been employed in many diseases, and particularly to prevent or remove the paroxysms of an *intermittent*. In the attack of this disease, there is a similar change of determination to that which has been described from the effects of the cold bath; and it is relieved by a similar exertion of the constitution. The cold bath, therefore, may be supposed to excite that exertion, and to render the subsequent relief more permanent and effectual; or, if the determination to the skin from the bathing has come on, the fit may be wholly prevented. The plan certainly has succeeded, and it is mentioned by Senac to have been useful even after the cold fit has appeared, (*De Reconditâ Februm Naturâ*, p. 218).

If *continued fevers* are only intermittents, whose paroxysms run into each other, so that the earlier stages are less observable, we may see some foundation for its use in these also. Remittents are confessedly of the same nature as intermittents; and in the Breslaw fever (the *trytæophya Wratislaviensis* of Sauvages), Dr

Hahn used the application of cold water with success. It brought on a glow of warmth; and, in the language of an ancient physician, *inde novi motus initium*. In some other cases of *typhus* it has been employed, seemingly with success; but in some late trials, at a period of the disease when the powers of nature were unable to excite these new motions, it was unsuccessful and even dangerous. Dr. Currie's practice of cold ablutions we shall soon consider.

In *ileus*, the practice of dashing cold water against the legs and thighs of a patient standing on a cold floor has certainly succeeded. It is mentioned by Brassavolus, as the practice of Savonarola, and is recommended by Hoffman (iv. 349). The latest author who seems to have employed it successfully is Dr. Stevenson (Edinburgh Medical Essays, vi. 895). We remember having tried it with little advantage. If sudden immersion in cold water has prevented threatening paroxysms of hysteria and epilepsy, it must be referred to altered determination.

The debility occasioned by continuing long in the cold bath has occasioned its employment in many instances, where the excitement of both the nervous and sanguiferous systems was morbidly increased. (See *Cold*.) In cases of phrenzy it has been employed with success; but the most striking instance of this kind is in Dr. Willis's work, *De Anima Brutorum*, p. 201. The most frequent cases in which its advantages have been conspicuous, occurred from phrenitic patients escaping their confinement, and running spontaneously to a river or pond. Applications of cold water to the head are frequently employed; but the more general influence of cold must produce a more powerful effect. There may appear to be some danger from rupture of the over distended vessels of the brain, but no such accident seems ever to have occurred.

In *scarlatina* Dr. Currie has lately shown the advantages of cold ablutions, and the necessity of continuing them steadily to obviate the violent heat which attends the paroxysms of this complaint; and he has been successfully followed with equal spirit and perseverance by Dr. Gregory. As the object is to abate heat, it is only used in this complaint when the heat is very violent, and continued until it is mitigated. In *small pox*, accident has also shewn its utility; and in the whimsical compilation of Dr. Baynard there are numerous instances of this kind. It has in this complaint also been continued till the extreme heat is repressed, and, on returning to bed, a gentle perspiration has come on; some of the pustules have filled, and the greater number in the skin have disappeared. Since the general progress of vaccination we shall probably have little occasion for this remedy, either communicated by air or water.

In *hæmorrhages*, cold-bathing, or, more frequently, cold applications, have been employed with the same views; nor, excepting in hæmorrhoids and hæmoptyses, has it been neglected: in the former, as a supposed critical discharge; and in the latter, from apprehension of accumulating the blood in the lungs. Cold drinks have, however, in hæmoptyses supplied their place; and it is doubtful whether the American practice of giving a solution of common salt may not derive part of its advantages from the cold of the water, which common salt however will not increase. The utility of nitre in all

hæmorrhages, is certainly increased by the cold it imparts to water during its solution. Hippocrates remarks, that the cold should be applied '*non supra ipsas partes, sed circa ipsas, unde profluit*.' The hæmorrhage most certainly relieved by cold is mænorragia, and particularly that of pregnant or puerperal women. It may be safely and advantageously carried to a very considerable extent.

In more *general fevers*, cold in every form is useful. In those of our own climate, cool air and cool drinks are perhaps sufficient. In those of warmer regions, however, the cold must be more actively exhibited. It is chiefly confined to such fevers as have considerable internal heat without topical affections; and whether, with Hippocrates, we give water *ὡς ψυχρότατον*; with Lommius and Avicenna, apply cold water or snow to the extremities; with Celsus, apply vine leaves dipped in water to the pit of the stomach; the principle is the same. Paulus Ægineta recommends bathing; and in later periods it has been employed by Dr. Stevenson. But the most striking and satisfactory case is that of Sir J. Chardin in the Gombon fever of the remittent kind, related by himself, in which the coldest drinks and the application of cold water externally were of the greatest service. The Neapolitan physicians, following the ancients, according to the plans detailed by Lommius, give the coldest drinks; and if faint sweats come on, the water is if possible rendered still colder with snow and ice; for Cyrillus adds, that 'a person who sweats while under this course, is in danger of losing his life by faintness.' If cold drinks do not produce this effect, 'the patient is uncovered, exposed to cold air, and continually fanned; and some have gone so far as to sprinkle snow powdered on the skin.' The *plague* is attended with great internal heat, and cold applications have been found useful. Dr. Baynard has detailed many rambling stories of this kind, and we apprehend that they have been of service in our late experience of this disease in Egypt. Dr. Rush used cold applications with advantage in the yellow fever.

In *mania*, cold bathing seems to have attracted the attention of Van Helmont, in consequence of an accident which happened to a carpenter at Antwerp, and he afterwards employed it designedly. The patient was immersed so long as was necessary to repeat, distinctly, the psalm '*Misererè*;' and, though he would be often taken up apparently lifeless, Van Helmont adds that he might be recovered; 'since people do not die from being under water so soon as is imagined.' It is however more to the purpose to remark, that this remedy is spoken of with respect by Boerhaave, and countenanced by Van Swieten.

The repeated action of cold bathing affords numerous opportunities of relieving some of the most troublesome and obstinate diseases to which the human frame is subject. Every complaint arising from debility in its varied forms and numerous consequences often yields to this remedy, when every other has proved ineffectual. *Palsy*, so often benefited by the stimulus of the warm bath, is greatly relieved by the tonic power of the cold; nor is the danger of its being improperly applied so great. It must not be used early in the complaint if the case is hemiplegia, nor until every symptom of congestion is removed. The partial palsies will not require even this precaution; but the cold is more useful if the water is poured from a height, or thrown from a pump, on the part affected.

*Chronic rheumatism*, we have said, is a paralytic affection of over distended vessels, and cold bathing is a singularly useful remedy. Sir John Floyer thinks it more beneficial if the patient is afterwards put between blankets to sweat. In the intervals of *gout*, if the patient is perfectly free from the disease, it is of service in restoring flexibility to the stiffened limbs, giving strength, and perhaps protracting, with safety, the return of the paroxysm. In stiffness of the joints, from old *strains*, or any cause, it is useful; and the sea bathing has been supposed particularly so in *white swellings* of the knee. In other forms of *scrofula*, bathing and drinking salt water alternately are very serviceable.

In the *hæmorrhages* without fever, called by pathologists *passive*, and in the *mucous discharges from relaxation*, the tonic power of the cold bath is useful. In those little fevers, connected with debility or owing to excess, it relieves; though it is doubtful whether it be from its tonic power, or, in the language of Petron, from its exciting new motions. In *chlorosis*, though it does not produce any very rapid benefit, it is often of the greatest service to the general health, and ultimately brings on the expected evacuation.

When *poisons* or *infectious miasmata* have been communicated to the animal body, we often find that they lie dormant, till some exciting and generally debilitating cause gives them activity. This renders cold bathing of use during the progress of an epidemic, and it is a valuable part of the prophylaxis. Bathing has been supposed also to prevent hydrophobia; but as few of the animals supposed to be mad are really so, and of those really bitten by mad animals, few are infected, the advantages from bathing are equivocal. If we look into the old authors, we shall find that bathing was employed with considerable severity, and with every circumstance that could agitate the mind and fix the attention. Tulpus, one of the chief advocates for the utility of this remedy, considers the mode of administration to be a very important part of the process; and it may have been so, for modern practitioners have not found it very successful. When narcotic poisons have been swallowed, and tremors, &c. have been produced, cold bathing has been very beneficial. Bæcius mentions its efficacy against the poison of the juice of the mandrake. The Indians are recovered from the stupefaction occasioned by the *datura*, by moistening the soles of their feet with cold water; dogs stupified by the carbonic acid air of the Grotto del Cani, are recovered by being thrown into the neighbouring lake; and sailors recover their intoxicated comrades by a dip in the sea.

The spasmodic and convulsive diseases are relieved by the tonic powers of the cold bath. In chorea, though often used, it is less successful, for reasons hereafter assigned; and in tetanus there is seldom time for the proper action of this remedy, though it has been employed with advantage. That convulsive diseases, when not produced by any direct irritation on a nerve, originate in debility, we trust to be able to prove in another article. See CONVULSIONS.

Sir John Floyer has remarked, that cold bathing is injurious in palsies when the patient is plethoric and feverish. It probably is so whenever any partial plethora or local obstructions exist in any of the more important viscera. Jaundice may perhaps be an exception

to this opinion. In the passage of a stone through the gall duct it seems to have been of service; but it was probably in cases where the liver was otherwise sound. In some of the western islands, a patient in the jaundice is laid on his belly, and a pail of cold water unexpectedly thrown on his back, (Smith's *Curiosities of Common Water*). It is injurious also when the stomach is full, or when the patient has been previously weakened. A ruptured blood vessel, or an incurable obstruction, may be the result of the former error; and in the latter case the constitution may not have sufficient power to restore the determination to the surface. When the body is heated it is also dangerous to bathe, though the young and strong transgress this rule with impunity.

Bathing IN THE SEA is on the whole preferable, as the heat is more uniform. It is, we think, also, perhaps from the agitation of the water, more refreshing. Other causes of preference have been assigned: one is, the greater pressure of the water impregnated with salt, the other, the stimulus of the salt left on the skin. Each may have some effect, and the latter ground of preference is assuredly more certain than the former. We cannot easily conceive how the momentary increase of pressure can have any considerable effect, except by the increase of momentum; and the stay in the sea is too short to expect much advantage from this source. The river water, heated from the vicinity of the shore, is less active than the sea water, whose heat is uniform in summer, and more so in winter; and the sea water, warmed from 75° to 82°, may be an useful bath for invalids preparatory to immersion in the sea. In these baths of a higher temperature the patient should stay a longer time than in the sea or fresh water. It is an observation of Galen, that a more temperate bath is not less useful than a cold one, if the stay be protracted in it.

The shower bath, a modern invention, in which the water falls through numerous apertures on the body, is a remedy much less pleasing, but probably more useful, than the sea or river bath. The cold is greatly increased from the momentum; and, as the water is usually taken from wells, its heat is uniform, about 51° in this climate, the mean of the earth. In winter the river water is much cooler, but generally superior in heat to the air. Bathing, therefore, through the winter is not a practice so severe as may be supposed, except when it is necessary to break the ice. Even then, however, the water below is higher than the freezing point, as its latent heat cannot escape, and the temperature of the air is often far below it.

The time of bathing should be as soon in the spring as settled weather can be obtained; and, from the long prevalence of easterly winds on the eastern coasts, the southern seem preferable at that time. The most advantageous part of the day is the morning, before breakfast; but, when the weather is not warm, and the patient is much debilitated, it may be proper to begin in the forenoon, after a light and early breakfast. The usual mode of immersion, first plunging the head, is undoubtedly preferable; but if the whole body is *very soon* immersed, this precision is of little importance. The stay in the bath is of more consequence: many come out after the first immersion, and indeed this is the most common, and often the most advantageous, method. It sometimes happens, however, that the glow

is so violent, as to leave in the subsequent part of the day a chilliness; and in such circumstances we have advised a second dipping, which, repressing the too violent determination to the surface, has rendered it more equable and permanent. If any debility arises from staying too long, some *warm* wine and water, *warm* tea, or any similar fluid, drunk frequently while the patient is laid between blankets, will relieve it.

It has been supposed that where the fluids are too much attenuated, bathing will be injurious. We have already said that we have scarcely any evidence of this taking place. We know from frequent experience that no such effect is produced by sea water; and if any of the neutral salt were absorbed independent of the fluid, it might produce the effect. Seamen, however, fishermen, and the sea bathers, who are constantly immersed in salt water, never experience any inconvenience from this cause.

One other form of cold bath has been employed, viz. the *cold air bath*. This consists only in exposing the body for a few minutes to the cold air, partly secured by a loose dressing gown. With prudent precautions this practice may be useful; and even salutary. The effects to be expected must depend on the heat of the atmosphere, and the temperature of the body when exposed to it. *Sponging* the whole body with cold water is of the greatest consequence, particularly in cases of chronic debility, where the cold bath cannot be obtained, or is from circumstances inadmissible. For the more partial use of cold applications, see *COLD*.

**BATHMIS**, (from *βασις*, *fundatus sum*). A seat, basis, or foundation.

Hippocrates and Galen use it to express a cavity of a bone which receives the protuberance of another at the joints, particularly those at the articulation of the humerus and ulna.

**BATHO'NIÆ A'QUÆ**. Called also *solis aquæ*, *badiqua aqua*. BATH WATERS.

Dr. Cheyne accounts for the heat of this water by the following experiment. If filings of iron and the powder of sulphur, made into a paste with water, are put into a cellar under a cock which drops water gradually and slowly, it will ferment, and the water running from it will be of the same heat and virtue with those of Bath, though not equally pleasant. Tournefort observes, "that the filings of iron will grow warm by steeping in common water, but much more so in sea water; and if powdered sulphur is added, the mixture will burn."

Most hot waters seem chiefly to consist of sulphur and iron, and to differ only as the sulphur or the iron predominates; where the sulphur most abounds, they are hotter, more nauseous, and purgative.

According to the Experiments of Dr. Bryan Higgins, a Winchester gallon of Bath water contains,

Of calcareous earth, combined with vitriolic acid, in the form of selenite	-	-	-	0	319 $\frac{1}{10}$
Of calcareous earth, combined with acidulous gas	-	-	-	-	0
Of marine salt of magnesia	-	-	-	-	0
Of sea salt	-	-	-	-	1
Of iron, combined with acidulous gas	-	-	-	-	0

Acidulous gas, besides what is contained in the above earth and iron, twelve ounces measure; and atmospheric air two ounces.

The four principal waters in England that possess any

remarkable heat, are those of Bath, Buxton, Bristol, and Matlock. The first of which raises Fahrenheit's thermometer from about one hundred and eight to one hundred and nineteen; the second to about eighty; the third to seventy-six; and the last to sixty-six or sixty-eight.

Dr. Monro, in speaking of these waters, says the highest degree of heat attributed to them by

Dr. Howard, the king's bath,	113	Dr. Charlton, hot bath	115	Dr. Lucas, cross bath	110	is from the pump of	119	of Fahrenheit's thermometer.
------------------------------	-----	------------------------	-----	-----------------------	-----	---------------------	-----	------------------------------

And that, on evaporation, a gallon has been found to contain of iron  $\frac{3}{7}$  or  $\frac{3}{10}$  parts of a grain; of calcareous earth  $22\frac{1}{2}$  grains; selenites  $31\frac{1}{2}$  grains; Glauber's salt  $25\frac{2}{3}$  grains; sea salt  $51\frac{1}{3}$  grains; which were mixed with an oily matter, but not more so than is common to all waters. From this and other accounts it appears that the Bath waters are acidulous chalybeates, in which iron and earth are kept suspended by means of aerial acid; and that they are impregnated with a small portion of selenites, sea salt, and muriated magnesia. Indeed these waters were for a long time esteemed to be sulphureous; but certainly they have not a title to that name in the least: they do not affect the colour of silver or metallic solutions, or produce any other effect of water impregnated with sulphur.

It has been doubted whether hydrogen or azotic gas is contained in these waters; and there was some probability that the latter was an active ingredient in them, but its existence has never been properly ascertained. Dr. Gibbs has lately added to their impregnations the siliceous earth. But we are still unable to discover in their contents any ingredient sufficiently active to account for their effects, and must resolve the question in the present state of our knowledge to the minute division of the substances dissolved; perhaps to these waters containing the proximate principles of some active compound. They operate powerfully by urine, and promote perspiration: if drunk quickly, and in large draughts, they sometimes purge; but if taken slowly, and in small quantities, they have an opposite effect. These waters are adapted to weak and exhausted constitutions, to atonic gout, to visceral obstructions, nephritic complaints, and dyspepsia. Externally they relieve in all the complaints for which the more active stimulant power of the *balneum* is employed. To the young and plethoric they are frequently injurious; and unless some evacuations are premised, often at first disagree, occasioning headach, heat in the hands, drowsiness, and giddiness. The seasons for drinking Bath waters do not greatly differ. In hot dry summers the waters are strongest, but the spring and autumn are preferred, from fashion probably rather than reason.

More than two pints in a day can never be required, which may be drunk at three or four times, a few hours intervening betwixt each portion; and in such chronic diseases as require preparations of iron, the artificial ones may at the same time be used. See Dr. Cheyne's Account of, and Dr. Falconer's Essay on, the Bath Waters; Monro's Treatise on Medical and Pharmaceutical Chemistry.

**BATHRON**. (Greek). The *seat of support*. It is also the *scamnum Hippocratis*, an instrument invented for the extension of fractured limbs. Oribasius and Scultetus both describe it.

BATHYPI'CRON, (from βαθυ, *exceedingly*, and πικρον, *bitter*). See ABSINTHIUM VULGARE.

BA'THYS. A sort of cheese formerly used in Rome.

BA'TIA. See CORNUMUSA.

BATI'CULA, (a dim. of βας, *a bramble*, from its likeness). See CRITHMUM.

BATI'NON MO'RON, (from βας, *a bramble*). See RUBUS IDÆUS.

BA'TIS, (from the same). See CRITHMUM.

BA'TOS, the BRAMBLE. See RUBUS VULGARIS.

BATRACHIOIDES, (from βατραχος, *a frog*, and εἶδος, *likeness*, from its resemblance to a ranunculus). See GERANIUM.

BA'TRACHIUM. See GERANIUM.

BA'TRACHOS, (from βατραχος, *a frog*). See RANULA.

BATTA'RISMUS, (from Βατλος, a Cyrenæan prince who stammered). See PSELLISMUS.

BATTA'TAS, (Indian). Called also *battata Virginiana*, *solanum tuberosum esculentum*, *kisfia kelengu*, *papas* vel *pappus Americanus*, and *convolvulus Indicus*. The common or VIRGINIAN POTATOE.

They were first brought into Europe by Sir Francis Drake in 1486, when he returned with the famous mathematician Mr. Thomas Herriot, who was sent to Virginia by Sir Walter Raleigh to explore the productions of the country. Herriot gave them to Gerard the botanist; who first planted them in London, and sent them to Clusius in Holland, who also planted them in Burgundy; and he sent them to Italy, as appears from the works of these and several other authors. It was from this introduction into Europe that so many writers say they were natives of Virginia; but it is said that they will not grow there without skilful culture.

Other authors have given a different account, and relate that the first cargo was shipped at Carolina for Ireland, but the vessel was lost near Liverpool. The potatoes that were saved were first planted there. Each may be true; and the former may refer to the first knowledge we acquired of them, the latter to the first importation.

They are of the natural order of *solanaceæ*, and the roots of the *convolvulus batatas* Ljn. Sp. Pl. 220. This is not the only instance where acrimony is inviscated by farina, or prevented from being evolved by keeping from the air. Those which grow near the surface are said to be poisonous. These roots are natives of both parts of the continent of America and of India.

The light mealy ones are the best, and, by proper management, a wholesome nourishing bread is made of them, called by the Peruvians *chunno*. Their use, as at present, is both profitable and salutary. More brandy may be obtained from an acre of potatoes, than from an acre of barley. They also afford much starch. They contain more than half their proportion of water, which renders them of easy solution and digestion in the stomach, and they are less liable to become ascescent and give the heartburn than the fermented cerealia. A cataplasm is made of potatoes, called CATAPLASMA SOLANI TUBEROSI. See AMBUSTA and ALIMENT.

The varieties of potatoes are numerous, and may yet be increased from the seed contained in the apples. But the usual method of increase is from the tuberosc roots. These are cut into pieces, each containing an eye similar to a bud on a branch, with so much of the medullary

substance connected with it as will nourish the young plant till it can draw by the roots.

Potatoes produced from sets, after a number of years, are found to decrease in bearing; for which reason they should be brought back every fourteen years to their original. It is after this period that those produced from the seeds themselves decline.

In Sweden, the leaves of the potatoe plants are manufactured for smoking instead of tobacco.

See on this article many remarks, both curious and profitable, in Hunter's Georgical Essays, Cullen's Mat. Medica.

BATTA'TAS CANADENSIS, also called *flos solis pyramidalis*, *heliotropium Indicum*, *adenes Canadensis*, *corona solis parvo flore*, &c. *helenium Indicum tuberosum*, *chrysanthemum latifolium Brasil*, *Americanum tuberosum*, *aster Peruanus tuberosus*, *Farnesianus solis Flos*. *HELIANTHUS TUBEROSUS* Lin. Sp. Pl. 1277. JERUSALEM ARTICHOKE. See ALIMENT.

BATTA'TAS PEREGRINA, called also *cacamotic flanoquiloni*. The CATHARTIC POTATOE; perhaps a species of *ipomœa*, nearly allied to *convolvulus*: '*cacamotic*' is certainly *quamoclit*, one of the species of *ipomœa*. Many worse blunders occur in the synonyms of the former editions. They grow spontaneously in the warmer parts of America. Their taste is very agreeable; and if about two ounces of them are eaten at bed time, they gently move the belly the next morning. As all the species are in a certain degree cathartic in some of their parts, this quality is less surprising.

BATTITU'RA, (from *batuo*, *to strike*). The squamous scales of metals which fly off whilst under the hammer.

BAU'DA. A vessel for distillation is thus named.

B. P. An abbreviation for *Caspari Bauhini Pinax Theatri Botanici*, sive Index in Theophrasti, Dioscoridis, Plinii, et Botanicorum, qui à Seculo scripserunt Opera.

B. THEAT. An abbreviation of *C. Bauhini Theatrum Botanicum*.

BA'URACH. From the Arabic term *bourach*. See BORAX, ANATRON, and NITRUM.

BAXA'NA. (Indian). A tree in an island near Ormuz, the smallest quantity of whose fruit is said to suffocate the person who tastes it, and the same effect to be the consequence of continuing under its shade; yet its root, leaves, and fruit, are antidotes to poison in other countries. It is also called *rabuxit*, Raii Hist. but not sufficiently described to be referred to its proper place in botanic systems.

BA'ZCHER. A Persian word for antidote. See BEZOAR.

BDELLA, (εδαλλα, *to suck*), BDELLERUM. HORSE LEECH. See also VARIX.

BDELLIUM, (from the Arabic term *bedallah*), called also *madelion bolchon*, *balchus*, and by the Arabians *mokel*, is a gummy resinous juice, produced by a tree in the East Indies, of which we have no satisfactory account. It is brought to Europe both from the East Indies and Arabia in pieces of different sizes and figures, externally of a dark reddish brown, somewhat like myrrh; internally it is clear and not unlike glue. To the taste it is slightly bitterish and pungent; and its odour is very agreeable. If held in the mouth it soon becomes soft and tenacious, sticking to the teeth. Laid on a red hot iron it readily catches flame, and burns

with a crackling noise; and, in proportion to its goodness, it is more or less fragrant.

Near half of its substance dissolves either in water or in spirit of wine; but the tincture made with spirit is somewhat stronger, and by much more agreeable. Vinegar, or verjuice, dissolves it wholly.

The simple gum is a better medicine than any preparation from it. It is one of the weakest of the deobstruent gums, but it is used as a pectoral and an emmenagogue. Applied externally, it is stimulant and promotes suppuration.

BEAN IGNATIUS. See FABA STI. IGNATII.

BEAN MA'ACCIA. See ANACARDIUM ORIENTALE.

BEAR'S FOOT. See HELLEBORUS.

BEAR'S FOOT. See UVA URSI.

BECABUNGA, (from *bach-bungen*, water herb, German, because it grows in rivers,) called also *anagallis aquatica*, *laver* Germanicum, *veronica aquatica*, *cephæa*: WATER PIMPERNEL, and BROOK LIME. The *veronica begabunga* Lin. Sp. Pl. 16.

It possesses in an inconsiderable degree the virtues of the cochlearia and nasturtium. It hath not the volatility of the cochlearia, nor is it pungent to the taste, but rather saltish and bitterish than acrid. It should be eaten plentifully as food, or a large quantity of the juice taken, if benefit is expected from it, as its powers are very inconsiderable.

BE'CHA, (from *βηχ*, a cough). Any medicine designed to relieve a cough, and of the same import as pectoral. The *trochisci bechici albi* of the London college consists of starch and liquorice, with a small proportion of Florentine orris made into lozenges, with the mucilage of gum tragacanth. It is a soft pleasant demulcent.

The *trochisci bechici nigri* consists chiefly of the juice of liquorice with sugar and gum tragacanth.

BE'CHION, BE'CHIUM, (from the same). See TUSSILAGO.

BE'CU'BA NUX. (Brasil). It is as large as a nutmeg, of a brownish colour, with an oily kernel in a woody brittle husk. A balsam is drawn from it, which is held in estimation in rheumatisms.

BEDE'GUAR, (from the Arabic *bedegua*). See CARDUS LACTEUS SYRIACUS, and CYNOSBATUS.

BEDENG'AN. The name of love apples in Avicenna: an esculent fruit of a species of solanum.

BE'GMA, (from *βηχ*, a cough). Hippocrates by this word means a cough and the *sputum* brought up with it.

BE'HEN A'LBUM, (from the Arabic term *behen*, a finger,) called also *jacea orientalis patula*, *raphantoides lutea*, and the true WHITE BEN, or BEHEN of the ancients.

BE'HEN A'LBUM VULG.; called also *lychnis sylvestris*, *lanaria*, *papaver spumeum vulg.* *muscipula frutensis*, *vesicaria*, SPATLING POPPY, BLADDER CAMPION, or WHITE BEN.

BE'HEN RU'BRUM, LIMO'NIUM, or LIMO'NIUM MAJUS.

BE'HEN SEA LAVENDER, or RED BE'HEN.

Two roots, viz. the red and the white ben, are described by the ancients. The white is a long, slender, white root, of an aromatic smell, and sharp taste; it is hard, but does not keep well. It comes from the East, and is the *centaurea behen* Lin. Sp. Pl. 1292. The red

is a thicker root, also brought from the East, and is the *statice limonium* Lin. Sp. Pl. 394. It is cut in slices, and tastes acrid; but the root of the white lychnis is used for one, and the root of the sea lavender for the other. The last grows in salt marshes on some of our sea coasts. It hath a thick root that runs deep in the earth, and is of an astringent quality.

BEIDE'LSAR, and BEIDELLO'PAR. A species of Asclepias, perhaps the *a. gigantea* Lin. Sp. Pl. 312, used in Africa as a remedy for fever and the bites of serpents. The caustic juice which issues from the roots, when wounded, is used by the negroes to destroy venereal and similar swellings. It resembles the apocynum and anemone.

BEJU'IO; called also the *habilla de Carthagena*, BEAN of CARTHAGENA, perhaps from the *Hippocrateu volubilis* Lin. Sp. Pl. 50. It is a kind of bean in South America, and is famed for being an effectual antidote against the poison of all serpents, if a small quantity is eaten immediately. This bean is the peculiar product of the jurisdiction of Carthage.

BELA'E. (Indian). A particular kind of bark of Madagascar, which was first presented by M. Saillant to the college of physicians at Paris. It is thin, of a yellowish colour externally, reddish within, and to the taste slightly bitter and astringent. It is said to be of considerable efficacy in diarrhoeas.

BELEMNOIDES, (from *βελεμνον*, a dart, and *ειδος*, shape). BELOIDES, and BELENOIDES: a name for the *processus styloides*, and of the process at the lower end of the ulna.

BELE'SON. See BALSAMUM.

BE'LI. See COVALAN.

BEL'LIA. (Indian). Called *frutex Indicus baccifer*. An Indian berry bearing shrub, a decoction of which is cooling. Raii Hist. The *mussaenda frondosa* Lin. Sp. Pl. 251.

BELLADO'NNA, (from *bella donna*, handsome lady, Italian). It is so called because the ladies of Italy use it to take away the too florid colour of their complexion. See SOLANUM LETHALE.

BELLEGU, BELLERE'GI, BELNILEG, BELLE'RICÆ. See MYROBALANI BELLERICI.

BELLIDIOIDES, (from *bellis*, the daisy; and *ειδος*, form). See BELLIS MAJOR.

BE'LLIS, (*à bello colore*, from its fair colour). The DAISY.

BE'LLIS MINOR; called also *consolida minima*, *symphythum minimum*, *bellis sylvestris minor*, BRUISEWORT, and COMMON DAISY. *Bellis perennis* Lin. Sp. Pl. 1249. It is too well known to need a description. Its leaves and flowers loosen the belly, are commended in disorders that arise from drinking cold liquor while the body was hot. The leaves are slightly acrid, the roots rather more so. They have a subtle penetrating pungency, that is not hot or fiery, but like the contrayerva. The root preserves this pungent matter when dried, and an extract made with water, or with spirit, retains the greatest part of its virtues. It is said to be an excellent antiscorbutic; but with all these fancied virtues it is wholly neglected.

BELLIS MAJOR, *consolida media* Lobelii, *bellidioides*, *leucanthemum bellidis facie*, *buthalmum majus oculis bovis*, OX EYE, MAUDLIN WORT, or GREAT OX EYE DAISY. It is the *chrysanthemum leucanthemum* Lin. Sp.

Pl. 1251. It is perennial, grows wild in corn fields and in dry pasture grounds; and flowers in May and June.

The leaves have been in esteem as diuretic and anti-asthmatic.

BELLIS LUTEA FOLII PROFUNDIS. See CHRYSANTHEMUM.

BELLIS MONTANA FRUTESCENS ACRIIS. See PYRETHRUM.

BELLO'CLUSUS, quasi BELL-OCULUS, a white gum dedicated to Bel, the Assyrian idol. A sort of precious stone resembling the eye; hence supposed to be good against its disorders.

BELLON. See COLICA.

BELLO'NIO and BELLO'NIS; so called in honour of Petrus Bellonius. See CEDRUS FOLIO CYPRI.

BELLONIUS DE AQUAT. An abbreviation of *Petrus Bellonius de Aquatilibus*.

BELLISTI PILLULÆ, BELOST'S PILLS. R. Hydragryri purificati,  $\frac{3}{4}$  iv. in syr. è spin. cervin.  $\frac{3}{4}$  i. extinct. resin. jalappii et pulv. colocynth.  $\frac{3}{4}$  i. f. massa cujus cap.  $\frac{3}{4}$  ss. 2<sup>do</sup> vel 3<sup>ia</sup> quaq. nocte.

BELLU'TTA TSJA'MPACAM. (Indian). Called also *amelpho* and *amelphodi*. The name of a large tree in Malabar. The root, powdered and taken with ginger, promotes sweat. A decoction of the leaves is a good expectorant, and it is said to be of service against the bites of serpents. Raii Hist.

BELLY. In medical language means the state of the intestines; as a *bound belly*, a *loose belly*.

BELLY of a MUSCLE. The larger fleshy part, in contradistinction to the smaller or tendinous extremities.

BELOE'RE. (Indian). An Indian evergreen plant. The seeds purge moderately, but the leaves roughly. Raii Hist.

BELOIDES, BELONOIDES, (from *βελος*, a dart, and *ειδος*, form). See BELEMNOIDES.

BELT. A bandage applied round the body. Mercury is used externally, by covering the internal part with its calx prepared by trituration; and some other medicines have been employed in the same manner.

BELUGA STONE. A morbid concretion from the beluga fish, *delphinus leucas* of Pennant. The Asiatics near the Volga suppose it useful in many complaints, and think it promotes delivery.

BELU'LCUM, (from *βελος*, an arrow, or dart, and *ἐλκω*, to draw out). An instrument for extracting darts or arrows.

BELUZA'AR. See ANTIDOTUM.

BELZU'AR MINERAL. See BEZOAR FOSSILE.

BEM TA'MARA, (from the Arabic term, *behen-tamara*). The EGYPTIAN BEAN. See FABA ÆGYPTIA.

BEN, (from *behn*, Arabic,) also called *balanus myrephica*, *glans unguentaria*, *nux ben*, *nux unguentaria moris*, *Coatlis*. The OILY ACORN, OILY NUT, or BEN NUT, probably from the *guilandina moringa* Lin. Sp. Pl. 546. Wahl and Willdenow have formed a new genus for this species with the appellation of *hyperanthera*. Loureiro styles it *anonia moranga*.

It is a whitish nut, of the size of a small filbert, roundish, triangular, with a kernel covered with a white skin. It grows spontaneously in the East Indies and America; and is brought also from Arabia.

These kernels have a nauseous bitter, oily taste, are

purgative, occasion a nausea and colic: on expression they yield one-fourth of their weight of a yellow oil, called *oleum myrephicum*; *balaninum oleum*, almost insipid and flavourless; for the nauseous bitter remains behind. This oil does not grow rancid by long keeping, as is common with expressed oils, on account of which it is used as the basis of odoriferous unguents and perfumes, and would be highly valuable for ointments were it easily procured. It is impregnated with the odour of jasmine, and other flowers, by stratifying them with cotton dipped in the oil, and repeating the process with fresh flowers until the oil becomes sufficiently odorous, after which it is squeezed out from the cotton in a press. This is also a name of the *behen*.

It is generally supposed that the *lignum nephriticum* is the wood of the tree which bears these nuts: q. v.

There is another species of ben much larger than the above. Monardus calls it *ben magnum*, seu *avellana purgatrix*, the GREAT BEN or PURGING FILBERT. It purges and vomits violently.

BEN'NATH. The Arabic name for small pustules which arise in the night after sweating.

BENEDI'CTA AQUA. A former appellation of the *aqua calcis simplex*; the name of a water distilled from serpyllum; and in Schroeder of an emetic.

BENEDI'CTA AQUA COMPOSITA; i. e. Aq. CALCIS. COMPOSITA. See CALX.

BENEDI'CTA HERBA. The HERB BENNET. See CARYOPHYLLATA.

BENEDI'CTA LAXATIVA. A compound of turbeth, scammony, and sparges, with some warm aromatics.

BENEDI'CTUM LIGNUM. See GUAIAECUM.

BENEDI'CTUM OLEUM. See LATERITIMUM OLEUM.

BENEDI'CTUM VINUM. See ANTIMONIALE VINUM.

BENEDI'CTUM LAXATIVUM. RHUBARB, and sometimes the LENITIVE ELECTUARY.

BENEDI'CTUS LA'PIS. See ADAMUS.

BENEDI'CTUS, (from *benedico*, to bless). A specific term affixed to many herbs and compositions, on account of their good qualities.

BENGA'LE INDORUM. From Bengal, its native place. See CASSUMUNAR.

BENINGA'NIO. A fruit which grows in the bay of St. Augustine: it is of the size of a lemon, red without, and grateful to the stomach. Raii Hist.

BENI'VI ARBOR, BENIVI'FERA, BENJAMIN, BEN'NJUI, BENZO'E, BENZO'IFERA, and BENZOIN. See BENZOINUM.

BENZOINUM, (from the Arabic term *benzoah*), called also *assa dulcis*, *assa odorata*, *liquor syreniacus*, or, *cyreniacus balzoinum*, GUM BENJAMIN. It is a concrete resinous juice, obtained from a middle sized tree, with leaves like the bay leaves, but not ribbed, and falling off in winter, bearing flattish nuts, the size of nutmegs, whose fleshy covering is externally rough and hairy. It is a native of the East Indies and of North America, particularly of Virginia and Carolina; but only brought from the East Indies: it grows in open ground with vigour in England. Mr. Dryander has fully ascertained this tree to be a styrax; hence it is called *styrax benzoin* Lin. Sp. Pl. Willdenow, vol. ii. 623, nat. order *bicornes*. It is the *STYRAX FOLIIIS oblongatis acuminatis subtus tomentosis, racemis compositis longitudine foliorum* Dryander. Philosophical Transactions, vol. 77, p. 308. The leaves

and the bark smell like the gum; and to rectified spirit of wine they give out a resin like the benjamin, but no resin naturally flows from it: the resin is obtained by incisions made in its trunk, about the origin of the first branches; as it runs out it is white, but soon becomes yellowish, reddish, or brownish. It is brought into Europe in brittle masses, composed partly of white, and partly of yellowish or light brown pieces. The white pieces are called *benzoes amygdaloides*, and are reckoned the best; they are hard, solid, shining, transparent, and possess a very fragrant smell: this gum resin hath but little taste, impressing the palate with a slight sweetishness; its smell is very fragrant if rubbed or heated, and it is less heating than most of the other balsams. Its specific gravity is 1.092; and though enumerated among the resins, it is in reality a balsam, uniting an oil with an acid: 100 parts contain 9 of acid,  $5\frac{1}{2}$  of acidulated water, 60 of thick empyreumatic oil, 22 of brittle coal, and  $5\frac{1}{2}$  of carbonated hydrogen and carbonic acid gas. If the oil is examined, 5 grains more of acid may be discovered. Brande Ap. Nicholson's Journal.

If pure it totally dissolves in rectified spirit of wine. By digestion it imparts to water much of its fragrance and pungency: the filtered liquor, gently exhaled, leaves a crystalline matter of a seemingly saline nature, amounting to an eighth part of the whole.

The FLOWERS of BENJAMIN, which is the gum sublimed, and purified, if yellow, by repeating the operation, partake of the fragrance of the resin: they dissolve in spirit of wine, and, with the assistance of heat, in water; from which they are prevented from separating, if as much sugar is added as will give the consistence of syrup to the water.

The *essential oil* of benjamin rises after the flowers, mixed with a little acid, and tainted with a slight empyreuma. It is purified by re-distilling it from water: the *tincture* is made by digesting four ounces of benjamin with a pint of rectified spirit; the *compound tincture*, dignified by the names of commander's and traumatic balsam, drops of life and Persian balsam, by digesting three ounces of benjamin, two of strained storax, one of balsam of Tolu, and half an ounce of socotorine aloes in a quart of rectified spirit. The *lac virginialis* consists of the tincture of benjamin in water, which becomes milky, and the gum deposited is the *magistery of benzoin*, and is chiefly the resinous without the saline part of the gum. In the original receipt of the commander's balsam, called also jesuit's drops, balsam of Berne, and friar's balsam, the ingredients were much more numerous, and the composition seems to have been warmer and more fragrant.

Of GUM BENJAMIN, the principal use is in perfumes, and as a cosmetic. It resembles in virtues and fragrance the storax and balsam Tolu, and may be useful in asthmias and other disorders of the breast, promoting expectoration: the flowers are also a powerful errhine. The flowers may be given from ten to fifteen grains, and the tincture in doses from eighty to one hundred and twenty drops, but is chiefly used to clear the skin and give a scent to wash balls. The *lac virginialis* must be used when a roughness or blotches render the skin unsightly: it may be rubbed on gently every day with a soft rag.

The flowers of benjamin are manifestly a saline sub-

stance of the acid kind, of some acrimony, and stimulant power. They have been recommended as a peccatorial; but Dr. Cullen has employed them in some asthmatic cases without effect: half a drachm appeared to be heating and hurtful. This is the benzoic acid of the chemists, which claims a share of our attention from its so often occurring in animal substances, though, as a medicine, it is almost, if not wholly, useless. About fourteen drachms of concrete acid may be obtained from a pound of benzoin, by Scheele's process, which is preferable to any other. Its specific gravity is 0.667. It is white; with difficulty reduced to powder; its taste sharp and pungent, subliming by heat, but not volatile in an ordinary temperature. Cold water dissolves  $\frac{1}{100}$  part of its weight, and boiling water  $\frac{1}{20}$ . Benzoat of lime is found in the calculi of herbivorous animals, and in some human concretions. The benzoats have not, however, been employed as medicines. From Hermsstaedt's experiments, Journal de Physique, vol. 34, it appears to contain some prussic acid. It has been reckoned among the correctors of opium; and, to prevent the latter checking expectoration, has been added to the old elixir paregoric, though without any particular advantage. It is also an ingredient in the balsamum traumaticum; and in fumigations has been employed as a corrector of foul air.

BE'RBARIS, BE'RBERIS, (from the Arabic term *berberi*, wild). Called also *oxyacantha* Galeni, *spina acida*, *crespinus*, *crispinus*; PIPERIDGE or PIPERAGE BUSH, and BARBERRY. The *berberis vulgaris* Lin. Sp. Pl. 471. Nat. order *trihilatæ*.

It is a large prickly bush, with brittle branches, covered with an ash coloured bark, under which lies another of a deep yellow colour. Some of the individuals have no seeds in their berries; and sometimes berries with and without seeds are found on one bush. It grows wild on chalky hills, flowers in May, and its fruit ripens in September.

The fruit is a mild restringent acid, useful in hot bilious disorders, and colliquative putrescent state of the fluids. The leaves have the same virtues as the berries, but in less degree. The inner yellow bark is austere and bitterish, gently purgative, and supposed to be useful in the jaundice. The bark of the root is mildly astringent. These barks do not keep long, and are best used by infusing one ounce of bark in a pint of water.

Simon Paulli recommends an essential salt of barberries under the appellation of *tartar of barberries*. Two ounces of lemon juice are added to two pints of the juice of barberries: they are digested, the liquor evaporated, and the salt suffered to crystallize. A *jelly of barberries* is made in the usual way. The vicinity of the barberry tree has been accused of communicating the fungus, on which what is called the *rust* depends, to wheat; and it was long since observed that the ears of corn in its neighbourhood were barren.

BERDIRA'MON. See BISTORTA.

BERE'DRIAS. The name of an ointment mentioned in Ætius.

BEREN'CE, (from the city of Berenice, from whence it was brought). See SUCCINUM.

BERE'NS SE'CUM. See ARTEMISIA.

BER'GAMOTE, or BER'GAMOT, (French). It is a species of citron, produced at first casually by an

Italian's grafting a citron on the stock of a bergamot pear tree, whence the fruit produced by the union participated both of the citron tree and the pear tree, and the plant is a variety of the *citrus medica* Lin. The fruit hath a fine taste and smell, and its essential oil is in high esteem as a perfume.

The essence of bergamot is also called *essentia de cedra*. It is extracted from the yellow rind of the fruit by first cutting it in small pieces, then immediately squeezing the oil into a glass vessel. This fluid is an ethereal oil.

A water is distilled from the peel by adding the outer rind of three bergamots to a gallon of pure proof spirit, and four pints of pure water: a gallon may be drawn off in a balneum mariæ, and as much of the best white sugar as will be agreeable must be added. It may be prepared also by distilling off three pints from the essence of bergamot three drachms and a half, rectified spirit of wine three pints, ammonia prepared a drachm.

**BERIBE'RI, BERIBE'RIA.** In the East Indies, the terms mean, in a medical sense, a species of palsy, in which, according to Bontius, patients seem to imitate sheep in lifting their legs when they walk. This palsy consists in a partial deprivation of the motion and sensation of the hands and feet, and sometimes of the body. Sauvages defines it under the order of *clonic spasms*: 'In walking, a retraction of the knee, with tremor; a sense of crawling, or tingling, and hoarseness, common in the Indies.' Linnæus describes it as 'a tremor of the parts, contracture of the knees, i. e. continual chronic agitation of the parts without a sensation of coldness, stupor, and hoarseness.' Sagar adds to the definition of Sauvages, 'painful stupor of the limbs.' He once saw some sheep, observing a wolf, seized with this spasmodic affection; and that they, whether standing still or walking, momentarily retracted their knees, which immediately returned to their natural situation. Dr. Aitkin makes it synonymous with *contracture*, which see. The cause is generally thought to be exposure to the cold vapours of the night too soon after exercise.

The cause of this disease is whatever weakens the moving powers, and relaxes the ligaments. Generally its approach is gradual; but sometimes it seizes suddenly.

The symptoms are, an universal lassitude, a faulty motion of the hands and feet, and the same throbbing titillation is felt in them as is felt in the fingers and toes in a cold country in the winter season, only the pain is not so great: sometimes the voice is so obstructed as to render articulation difficult. The disease is not mortal, except by seizing the muscles of the breast, so as to obstruct respiration and the voice.

In the cure, moderate exercise and frictions are useful: the Indians use a semicupium made of water, in which is boiled an aromatic herb called *lagondi*, or, in want of it, camomile and melilot. The affected parts are rubbed well with a mixture of the oils of mace and roses. Bleeding is not required; but, on the contrary, warm nervous strengthening restoratives are to be used, with an occasional gentle purge. Decoctions of sarsaparilla and guaiacum are also of service. See Bontius De Medicinâ Indorum.

**BERICO'CCA.** A corruption of the Tuscan language from *PRÆCOCCA*, which see; and also *ARMENIACA MALA*.

**BERMUDE'NSES, BA'CCÆ,** (from *Bermudas*). See *SAPONARIÆ NUCULÆ*.

**BE'RNAVI.** An electuary mentioned by Prosper Alpinus in his work *De Medicinâ Ægyptiorum*. It is prepared in India; its composition is unknown; but very extraordinary effects are attributed to it.

**BERNHA'RDII TESTI'CLUS.** See *ASPHODELUS LUTEUS*.

**BERNHA'RDII EREMI'TA.** See *CANCELLUS*.

**BERRIO'NIS.** See *COLOPHONIA* and *JUNIPERIGUM*.

**BERS.** A sort of electuary used by the Egyptians to promote gaiety; it contains opium, and creates a temporary delirium.

**BE'RULA.** See *BECABUNGA*.

**BE'RULA GA'LLICA.** See *SIMUM ANGUSTIFOLIUM*.

**BERY'TION,** from Berytus, its inventor. The name of a collyrium described by Galen as good against an ophthalmia; and of a pastil against the dysentery.

**BES.** See *CYATHUS*.

**BE'SACHER.** See *FUNGUS* and *SPONGIA*.

**BE'SASA.** See *RUTA*.

**BESL. FA'SCIC.** An abbreviation of *Basilii Besleri Fasciculus rariorum*.

**BESL. GAZOPHYL.** An abbreviation of *Gazophylacium Rerum Naturalium Michaëlis Ruperti Besleri*.

**BESL. HORT. Ezs.** An abbreviation of *Besleri Hortus Eystetensis*.

**BESO'NNA.** Rulandus explains it by *muscarum fungus*. Probably he means a *sponge*.

**BESSA'NNEN.** An Arabian term. In Avicenna it is a redness of the external parts, resembling that which precedes the leprosy: it occupies the face and extremities. Dr. James thinks it is what we call chilblains, but is more probably erysipelas. See *PERNIO*.

**BE'STO.** See *SAXIFRAGA*.

**BE'TA.** So called from the river Bætis in Spain, where it grows naturally; or from the Greek letter β, *beta*, which when turgid with seed it is said to resemble. **BEET.** It grows on some of the sea coasts of England and Holland. There are numerous varieties of the *beta vulgaris et maritima* Lin. Sp. Pl. 322, distinguished rather from their colour than their properties; and a wild sort called by Dioscorides *limonium*. The parent of all is probably the *b. maritima* Lin. The mangel wurtzel, with whose wonderful virtues the world was some years since so much amused, is a variety of the *b. cicla* Lin. From the *b. vulgaris* M. Achard has attempted to extract sugar, hitherto with little success. By a miserable pun, both have been said to be *baits* for popularity.

*Beets*, used as food, are difficult of digestion, and afford but little nourishment. If freely eaten they are laxative and emollient. The red ones give out their colour to spirit of wine; and on expression the colour accompanies their juice.

The juice of both kinds has been considered as a powerful errhine, occasioning a copious discharge, without sneezing; but Dr. Cullen observes, in the trials he made, the juice snuffed up the nose gave no large or durable evacuation. The dried red beet roots yield one-twentieth part their weight of sugar, and the dried white beet roots one-tenth.

**BETLA.** (Indian.) Called also *betre*, *betele*, *bethle*, *betelle*, *BETLE*, and *bulatwacla*.

It is a scandent plant, growing in different parts of the East Indies, bearing a fruit which resembles a lizard's tail; its taste is agreeable; and the ancient botanists confound its leaf with the malabathrum. It is, however, a species of piper, viz. *p. betele* Lin. Sp. Pl. 40. Another species growing in Java is the *p. scriboa* P. 41.

Mixed with other things, as fancy directs, the Indians chew it almost continually. It is gratefully cordial, but seems to injure their teeth.

**BETO'NICA**, corrupted from *vetonica*, perhaps from Vetones, a people of Lusitania. Called also *vetonica cordi*, *cestrum*, *drosiobetanon*, COMMON or WOODY BETONY. The *betonica officinalis* Lin. Sp. Pl. 810. Nat. order *verticillatæ* or *labiatæ*.

The leaves and tops are somewhat disagreeably scented, but the odour soon flies off from the dry herb: to the taste they are warm, rough, and bitterish; if powdered, they make a good errhine.

An infusion of the leaves in boiling water contains all the virtue of the herb, and is its best preparation. From large quantities a small portion of essential oil is obtained by distillation. The roots are said to be nauseous and emetic; and, as a medicine, very similar to the helleborus albus. Scopoli thinks it a cephalic and a tonic. It is an ingredient in Rowley's British herb snuff.

**BETO'NICA AQUATICA.** See SCROPHULARIA AQUATICA.

**BETO'NICA PAU'LL.** See VERONICA.

**BETO'NICA CORONA'RIA.** See CARYOPHILLUS RUFER.

**BE'TRE.** - See BETLA.

**BETTO'NICA.** See BARDANA MAJOR.

**BETULA**, (from *batuq*, to beat, because rods are made of its twigs). The BIRCH TREE. The *betula alba* Lin. Sp. Pl. 1393. Nat. order *amentaceæ*.

If this tree is wounded in the spring pretty deeply into its trunk, there gradually issues a large quantity of a limpid sweetish juice. It is best when drawn from the upper part of the tree: soon after the leaves have begun to appear, the juice loses its sweetness. This juice hath been drunk as an antiscorbutic; it sensibly promotes urine, and, freely taken, proves laxative. It has been used in diseases of the skin, and against worms. By fermentation it becomes a vinous liquor; and, inspissated to the consistence of a syrup, it yields in cool places a brownish concrete like manna.

The leaves and bark are antiseptic. The former are applied to erysipelatous inflammations, and the latter is burnt to correct bad air; and for this purpose it is the next in goodness to juniper. The oil is sweet, but not particularly employed: that of the epidermis is black.

**BEUTU'A.** See PAREIRA BRAVA.

**BEX**, (from *βρυα*, to cough). See TUSSIS.

**BEXU'GO.** The root of the *clematis Peruviana* of C. B.; one drachm of which is enough for a purge.

**BEXUGU'ILLO.** The PERUVIAN IPECACUANHA. See IPECACUANHA.

**BE'ZOAR**, so called because it is found in the stomach of the sort of goat named *bezoar*. This is originally a Persian word, viz. BADZCHER, or LAZCHER, or PHAHAZAR, which signifies an *antidote*. Avenzoar is

the first who mentions it as a medicine, or who gives its history.

Bezoar stones are preternatural or morbid concretions formed in the bodies of many animals; they are composed of several strata, or layers, like an onion. In the Hist. de l'Acad. an. 1703, it is asserted, that all bezoar stones are bilious concretions of the respective animals which afford them.

Bezoars may be divided into: 1. The true oriental and occidental. 2. Animal concretions which resemble bezoar; as those from apes, and even the various species of pearls and crabs' eyes. 3. The several species of fossil bezoars. 4. Those which have only the shape, without the virtues of bezoar, as the calculi in the human bladder, kidneys, and gall bladder; or in the same parts of oxen. 5. The *ægragropila*, balls of matted hair, and bezoar Germanicum, see CAPRA ALPINA.

**BE'ZOAR ORIENTA'LIS**, called also *lapis bezoar*, *hircus bezoarticus*, and the ORIENTAL BEZOAR STONE, from the East Indies. It is supposed to be produced in the cavity at the bottom of the fourth stomach of a species of goat in Persia called *parau*. *Antelope gazella* Lin. though not peculiar to this species, as it occurs also in the *antelope cervicapra* and the *capra ægagrus* Lin. It is only found in the old ones, and exclusively in those which feed on particular mountains.

This stone, finely powdered and levigated with spirit of wine, was formerly made into balls, which were called GASCOIGNE BALLS, from Gascoign their inventor. What are at present sold under that name by the trading chemists, if any remain, are a sophisticated medicine without bezoar.

**BE'ZOAR OCCIDENTA'LIS**, called also *lapis bezoar*, *Peruvianus*, the AMERICAN or OCCIDENTAL BEZOAR, from the West Indies.

It is found in the stomach of an animal of the stag kind, called *animale bezoarticum occidentale*, a native of Peru, and other parts in the Spanish West Indies; and in the stomach of the yzard of the Alps, *antelope rupicapra* and *capra ibex* Lin.

**BE'ZOAR HYSTRI'CIS**, (from *ὕστρος*, the hedge hog, because its spots resemble the bristles of an hedge hog,) *pila hystricis*, *bezoar porci*, *lapis porcinus*, *petro del porco*, *lapis Malacensis*, the PORCUPINE BEZOAR, or GALL STONE. It is found in the gall bladder of an Indian porcupine, particularly in the province of Malacca, of a roundish figure, and of a pale or purplish colour, or between a green and white; it is soft, smooth, and slippery to the touch; to the taste intensely bitter, and the water in which it is steeped soon becomes bitter also. It does not appear to differ from the biliary concretions of an ox or any other animal. It is carried in the pocket as an amulet, and hired in Portugal at about a shilling a day.

**BE'ZOAR SI'MIÆ**, or **LA'PIS SI'MIÆ**, the BEZOAR of the MONKEY. Stones of this kind are found in the stomach of certain monkeys in Brasil and the East Indies, though they rarely produce them. They are about the size of hazel nuts, harder than the oriental bezoar, of a dark green colour, almost black. The scarcity renders them costly, and they are seldom to be met with. Bezoars are also taken from the stomachs of

crocodiles, dogs, mules, and the *camelus vicugna* Lin. All the true bezoars, when rubbed, exhale a perfume; and, when cut through, are found to contain a nucleus of vegetable matter, successively covered by laminæ of an ammoniacal magnesian phosphat, mixed with a coloured extractive vegetable matter, and animal fluids of a bilious kind. These give the green colour and the smell of musk. On the molares of ruminant animals there is a brown golden coloured coat, like that on the surface of their bezoars. Fourcroy has analysed the oriental bezoars with some care, (*Annales du Muséum d'Histoire Naturelle*, vol. i. p. 111). He considers them as an animal resin different from every concretion. They are softened by heat, easily penetrated by a hot needle, exhaling an aromatic and musky odour; they burn and inflame with a thick smoke, impart a colour to boiling water, and wholly dissolve in alcohol, which they colour. They are dissolved by caustic alkalis, differing in this from vegetable resins.

The false bezoars are prepared with powdered oyster shells made into small balls with gum water, and perfumed with ambergris. They effervesce with acids, and, when cut, have no concentric laminæ; nor, when broken, any crystalline striæ; nor, when rubbed on paper previously covered with chalk, do they leave an olive coloured mark. The *Goa* and *Malacca stones* are of this kind.

BEZOAR FOSSILE. FOSSILE BEZOAR is a small hollow body from Italy, found in sand and clay pits, of a purple colour, with a rough surface, the size of a walnut, and light. When broke, it is found to consist of an iron crust, containing in its hollow a fine greenish white earth resembling pale bezoar. The earth is used, and not the shells. It seems to be of the nature of bole armoniac, or rather calcareous; and is also called *bezoar minerale*, *terra sicula et noceriana*, *lapis bezahan*, *siculus albus*, *bezuar minor*. SICILIANA, MINERAL BEZOAR, and SICILIAN EARTH.

Notwithstanding all the boasted virtues of these bezoars, viz. the power of destroying poisons and reanimating the vital powers, it is certain that they are absolutely indigestible in the stomachs of the animals in which they are found; and they are equally so in the human, except when accompanied with an acid; so that no more can be expected from them than from any of the testacea that are soluble in acids; but they are inferior to them, as far less absorbent, and more difficultly acted on by any acid.

BEZOAR MICROCOSMICUM, called also *calculus humanus*, the calculus of the human bladder.

It is various in its degrees of hardness, as well as in its size and figure. It has been used in the place of the more costly sorts.

BEZOAR ANIMAL'LE. ANIMAL BEZOAR. Take the whitest calcined hartshorn levigated to the greatest subtilty, pour on it, drop by drop, the spirit of vitriol, to form it into a paste to be made into balls.

A powder of liver and heart of vipers is called *animal bezoar*.

BEZOAR BOVINUS, called also *alcheron lapis*. The Portuguese call it *MESANG DE VACA*. It is a stone found in the gall bladder of a bull.

BEZOAR MINERAL. See BEZOAR FOSSILE.

BEZOAR'DICA RA'DIX. See CONTRAYERVA.  
BEZOAR'DICUM JOVIA'LE. BEZOAR with TIN.  
See ANTIMONY.

This differs very little from the anti-hecticum Poterii, and might as well be prepared by simple deflagration with nitre, since it is a mere calx.

BEZOAR'DICUS PULVIS. See BEZOAR ORIENTALIS.

BEZOARTICUM, BEZOARTIE; such was the opinion of the ancients respecting the virtues of bezoar, that physicians held it as a medicine highly efficacious in a vast variety of cases, particularly as a counter poison or alexipharmic, and placed a very great dependence on its powers; therefore, all medicines supposed to possess similar virtues, were termed bezoartica.

BEZOARTIEUM MINERALE. The common calx of antimony generally supplies its place, for, like that calx, it is absolutely inert.

BIA'NCA ALEXANDRI'NA. See ALBUM HISPANICUM.

BIBITO'RIOUS MU'SCULUS, (from *bibo*, to drink). See ABDUCTOR OCULI.

BI'BULUS LAPIS, (from *bibo*, to drink, so called from its drinking or absorbing power). See PUMEX.

BICAUDA'LIS MUSCULA'RIS, vel INTRICATUS MU'SCULUS, (from *bis*, twice, and *cauda*, a tail, so called from having two tails). See ABDUCTOR AURIS, N° 1.

BI'CEPS MU'SCULUS, (from *bis*, and *caput*). A DOUBLE HEADED MUSCLE.

BI'CEPS HU'MERI, called also *biceps internus humeri*: Dr. Hunter calls it *biceps flexor*. It rises by two heads; one of them, which is a slender tendon, from the uppermost part of the glenoid cavity; it runs across, within the cavity of the joint, under the ligament of the articulation, passes in the groove between the two tubercles, and, going down, grows fleshy. The second head rises from the extremity of the coracoid process, runs down the axilla, and joins the first, forming a tendon, which sinks between the interstices of the muscles, to be inserted into the tubercle on the inside of the radius. This muscle, besides being a flexor, acts as a rotator of the radius, when the hand is prone. This muscle sends off an aponeurosis towards the inside of the arm, which is the part wounded when the tendon is said to be pricked by bleeding. This aponeurosis was first noticed by Cowper.

BI'CEPS EXTE'NSOR. This muscle rises by two heads; the longer, taking its origin from near the neck of the os humeri, runs between the *teres major* and *minor*, down the back part of the arm, and joins the short head which rises on the outside of the deltoid, and is inserted into the olecranon.

BI'CEPS FE'MORIS. This muscle hath two heads; the longer rises in one mass with the *semitendinosus*, but, having advanced a little way, they part: they arise from the protuberance of the ischium on its back part; as the biceps advances it becomes fleshy. Between the biceps and the *semitendinosus*, the vessels lie in the ham. The short head rises from the *linea aspera*, between the insertion of the biceps and the origin of the *vastus externus*. The two heads join, and are inserted into the superior epiphysis, or outer part of the fibula.

It bends the tibia, and partly rotates the leg by turning the foot outwards. Cowper.

BI'CHOS, (from *bicho*, *fort*). A Portuguese name for the worms found under the toes in the Indies, and which are destroyed by the oil of the cashew nut.

BI'CION, (from *βίκος*, a *fitcher*, from the shape of its pod). See Vicia.

BICO'RNE OS, (from *bis*, *double*, and *cornu*, *horn-ed*). See HYOIDIS OS.

BICO'RNIS, (from the same). A muscle is so called when it hath two terminations; also a name of the *flexor carpi radialis*, and of the *extensor carpi radialis*.

BICU'SPIDES, (from *bis*, *twice*, and *cuspis*, a *point*). DOUBLE POINTED. See MOLARES.

BI'DENS, (from *bis*, *twice*, and *dens*, a *tooth*,) so called from its being deeply serrated or indented: called also *verbesina*, *cannabina aquatica*, *hepatorium aquatile*, *eupatorium Arabum*, *ceratocephalus*, AGRIMONY, and WATER HEMP. *Bidens tripartita* Lin. Sp. Pl. 1165. Nat. order *discoideæ*.

The leaves have a light agreeable smell, and pungent bitter taste; are supposed to be aperient, corroborant, and of some efficacy in icteric complaints, scurvy, and œdematous swellings of the feet. An infusion in boiling water, drunk freely, is the best method of using them. The juice of the fresh herb may be taken in doses from one to two ounces: larger doses operate by vomit and stool, and the root purges actively.

BI'DENS ZEYLA'NICA, BI'DENS URTICA. See ACH-MELLA.

BIE'NNIALIS, (from *bis*, *twice*, and *annus*, a *year*). BIENNIAL. Herbs are said to be *biennial* when their roots continue two years.

BI'FIDUS, (from *bis*, *twice*, and *findo*, to *cleave*). BIFID, cloven; called also *dicaeus*.

BIFO'LIUM, (from *bis*, *twice*, and *folium*, a *leaf*,) because it sends up two leaves upon one stalk: also called *ophris*, *ophris major*, *orchis bifolia*, *didyme*, ordinary WOOD BIFOL, and COMMON TWAYBLADE. *Ophrys ovata* Lin. Sp. Pl. 1340. It is found in woods and other shady places, flowers in June, and ranked among the agglutinant astringents. Miller's Bot. Off.

BIGA'STER, (from *bis*, *twice*, and *γαστήρ*, *belly*). A name given to muscles that have two bellies.

BIGNO'NIA CATA'LPA, Lin. The leaves, as Thunberg informs us, are applied with success to limbs affected with rheumatic pains by the Japanese.

BILA'DEN. See FERRUM.

BILIA'RIA ARTE'RIA, (from *bilis*, *appertaining to bile*). The BILIARY ARTERY. When the hepatic artery hath advanced as far as the vesicula fellis it gives out the *biliaria*, which accompanies the two cystic branches in the gall bladder, and then is lost in the great lobe of the liver. See HEPATICA ARTERIA.

BILI'MBI. (Indian). A tree of about eight or ten feet high, which Bontius calls *billing bing*; and by the Europeans it is named *malus Indica*, *fructu pentagono*. *Averhoa bilimbi* Lin. Sp. Pl. 613. Nat. order *terebinthinaceæ*.

It is cultivated in the gardens in Malabar, bears flowers and fruit all the year. The juice of the root is cooling; that expressed from the fruit cures the itch, and several other diseases, if applied by laying on linen cloths that have been dipped in it. Inwardly taken, it

abates the gripes and a diarrhœa. The ripe fruit is eaten as a delicacy, the unripe made into a pickle for the use of the table.

There is another species called *neli foli*, or *bilimbi altera minor*, *averhoa acida* Lin. The male species of the *nebihouli* is called *alahouli*. Râii Hist.

BILIO'SA FE'BRIS, (from *bilis*, *bile*). The BILIOUS FEVER; called also the MARSH, REMITTENT, AUTUMNAL REMITTING, and CAMP FEVER. *Febris flava*, *febris maligna Barbadosensis*, *icterodes*.

When a fever is accompanied with bilious discharges by vomit or stool, whether it be continual, intermittent, or remittent, it is called *bilious*. It is the second species of typhus in Dr. Cullen's Nosology, named *icterodes*, defined a typhus with yellowness of the skin. In his First Lines, vol. i. he observes that the typhus is a genus that comprehends several species; that these, however, are not well ascertained by observation; many of the different cases do not imply any specific difference, and seem to be merely varieties, arising from a different degree of power in the cause, from different circumstances of the climate or season in which they happen, or from different circumstances in the constitution of the persons affected. One effect, arising from these circumstances in the constitution of the persons affected, is an unusual quantity of bile appearing in the course of the disease, which is almost a distinguishing character of intermittent fevers; but if it should appear with a continued fever, it could only be considered in such a case as a coincidence owing to the state of the season, producing no different species or fundamental distinction, but merely a variety of the disease.

In Britain it generally prevails in the first cold that succeeds hot weather; in hot countries it is most frequent in damp marshy places, and after great rains that are followed by great heats. In both situations, those who are exposed to damps, and to the night air, are most subject to it.

Besides the causes in general of fevers, it is occasioned by a copious secretion of the bilious fluid poured into the duodenum and stomach, whence the symptoms proper to this fever arise.

Besides the usual symptoms of fever, there are an extraordinary inquietude and anguish, a burning heat, cardialgia, nausea, vomiting, and purging; and, in consequence, a copious discharge of bile. The thirst is excessive, and the dejection of spirits equally so; the pulse is small but quick; sometimes it remits very sensibly, at others the remissions are more obscure; and at last an inflammation of the bowels comes on. If the evacuations are cadaverous, death is approaching; and an involuntary discharge of the excrements is usually fatal.

If the pulse is full and hard, bleeding may be admitted in the beginning; a repetition is rarely, if ever, required; and in hot countries it is best to omit this evacuation. In all cases a grain or two of antimonium tartarisatum, as an emetic, is necessary.

If saline medicines are given, the citrated potash is the most proper; but each dose should be administered in the act of effervescence.

As soon as an intermission is perceived, the bark, which is the chief dependence, must be given. But if the disease be very violent, or the disease occur in a

hot climate, the bark must be given before the intermission, for on its early use depends the cure; a drachm may be given every hour in wine and water, or what the patient uses for his common drink. If the bark, in substance, is not agreeable, a cold infusion of it may be substituted, which may be acidulated with the acidum vitrioli dilutum, and the patient may take it as freely and frequently as his stomach will bear. If it excites stools or vomiting, a few drops of the tinct. opii will prevent the inconvenience.

In colder climates and less urgent circumstances, the pulv. rad. columbo, gr. xv. ad xx. with the kali vitriolat. ℞ i. ad ℞ ii. given every four, five, or six hours, produce both speedy and beneficial effects. The neutral salts, Dr. Percival observes, abate the febrile heat, allay thirst, and bring on a gentle salutary diarrhœa; whilst the columbo supports the patient's strength, obviates the sickness, and checks the septic ferment in the primæ viæ. Dr. Haygarth adds, that after the primæ viæ are cleared from their bilious contents, the columbo root allays the nausea so constantly attendant on this disorder: and that in this fever, though the remissions are very evident, and the accession marked with chills and other symptoms of an intermittent, yet the bark is not always so successful in this climate as to encourage its use. The columbo, he observes, answers our warmest wishes, by correcting the bile, restoring the proper tone of the stomach, and of the whole habit; it also prevents relapses, to which, in this fever, the patient is peculiarly disposed.

*BILIO'SA A'RDENS FE'BRIS.* The BURNING BILIOUS, called also the YELLOW, FEVER, the West Indian fever. It is a variety of the *typhus icterodes* of Cullen, and has no connection with the *biliosa febris* just noticed, except in the bilious discharges, and the colour of the skin. This, as just observed, is a typhus of a very rapid and dangerous kind, as nervous debility, torpor, and mortification, soon come on. It is the fever which has made such considerable devastation on the North American continent, and, with a little variety, in Spain and Gibraltar. It has proved a more general and fatal epidemic than any other, the plague excepted, to which it bears no inconsiderable relation. This subject we must however soon again return to.

It attacks with a transient chillness and shivering, which are soon succeeded by a burning heat all over the body, but more particularly about the præcordia: the pulse is high and quick, but not hard; the eyes are heavy, the face flushed, a violent headach comes on, with beating in the temporal arteries, and a thick laborious respiration; a nausea soon follows, and what is discharged upwards is black and highly bilious. Anxiety is very great; a shooting pain is complained of in the back and loins, and an uneasy lassitude in the limbs. In about twelve hours after the first invasion of this disease, the tongue is very dry, rough, and discoloured; thirst is excessive, vomiting incessant, anxiety increased, a soreness is felt all over the body, and a delirium comes on. In the last stage, which soon arrives, the patient labours under a coma, manifests a great oppression about the præcordia, the respiration is very difficult, the face swollen and darkly yellow, and at length the tendons tremble; cold sweats and convulsions usher in death. Blood taken the first day is florid but thin, and the crassamentum scarcely coheres: on the second or

third day it is still more loose, and the serum is more yellow. When the patient recovers, the crisis usually happens in the fourth day after the attack, and generally discovers itself by a brighter suffusion of the bile all over the body. The yellow tinge sometimes appears in the eyes twelve hours after the symptoms of this fever come on; the sooner it appears the more favourable is said to be the prognostic. This however is not correct, for the bilious suffusion is only salutary when the disease is protracted. If the skin continues dry and rough the patient rarely recovers, however good his pulse may be. Incessant vomiting, and the discharges growing darker coloured, with dark spots on the skin, are fatal signs; and if a dry skin accompany an inflamed redness of the eyes, death may be expected in a few hours.

The violence and fatality of this disease have directed very powerfully the attention of physicians to its nature, and particularly of those who have been engaged in the conduct of such epidemics. As it obviously occurred at the period when autumnal remittents were common on the American continent and in the southern parts of Europe, it was highly probable that this was only the usually returning epidemic, from accidental circumstances rendered more violent and fatal. Yet when its nature was more closely examined, this idea was entertained with greater hesitation. It was obviously bilious, but less clearly remittent; its rapid progress did not keep pace with that of the true bilious fever, and symptoms of peculiar debility came on in a very early stage. In short, it was highly probable that it was a typhus, attended with bilious symptoms, rather than a remittent of a peculiarly malignant kind. Some little remission may be observed in the earliest stage, but it is transient, and perhaps not more than by careful attention may generally be observed in typhus.

When the violence and malignity of the disease were ascertained, no country was willing to claim the destructive visitant. It was supposed to be an importation, and probably was so. At Martinique it was the fever from Siam: in America, from Bulam. The discussion would be too long; but, from a careful examination of all the facts, it appears probable that some contagion, uniting with the epidemic tendency of the bilious autumnal remittent of the country, has produced the destructive monster. The observations in Philadelphia seem to trace it to some foreign importation. At Martinico, at Grenada, and Jamaica, there appears always to have been a concurring cause. It is doubtful, however, whether this is constantly contagion. The putrefaction of vegetable and animal substances, which in any situation may occasion typhus, in concurrence with the autumnal remittent, may produce the yellow fever.

These views will discriminate it from the *causus*, from the gaol and hospital, as well as from the common bilious fever. In the gaol fever there are little accumulation and discharge of bile: in the others, little of the asthenic and putrefactive state. When we consider fever more generally, we shall distinguish these states, and point out in what cases putrefaction may produce debility, and where debility occasions putrefaction. The yellow fever and the plague are, we think, referable to the latter; and the distinction is not an object of curiosity and refinement only, for it assists in directing the cure, particularly the exhibition of the Peruvian

bark. Much idle—it is an improper word—many highly pernicious disquisitions have been indulged, whether this fever is contagious. The existence of a doubt shows that it may not be highly so. Yet it has in so many instances been communicated from an infected person, that the utmost caution is requisite. It has been even doubted whether the plague is contagious; but those who have suggested and disseminated the doubts, are answerable for the lives of thousands, and in some instances have paid the forfeit with their own.

On dissection, the contents of the brain and thorax were uninjured; but the blood is fluid like that of persons who have been destroyed by electricity. The stomach and duodenum were generally inflamed; sometimes a little extravasation; sometimes pus and a black fluid, black, generally from containing flakes, and evidently a depraved secretion of bile, were observed. On the surface of the other viscera some distended veins were seen, but the liver was generally sound. Negroes and mulattoes escaped better than the white inhabitants, and those were less frequently and violently affected than strangers. In America, however, the inhabitants and strangers were equally susceptible of the disease.

The American physicians have differed greatly in opinion, whether this fever was an inflammatory or a putrid one. The difference has, we fear, led each party to an injurious plan of treatment: which, as usual, has been pursued with more pertinacity, because it was their own system. We see in this disease, as we have said, an asthenic fever, joined with biliary accumulations; a fever hastening rapidly to a fatal termination, while we do not possess a power of supporting the strength without previously exciting proper discharges; or of producing the necessary evacuations without inducing a fatal debility. The great debility, the anxiety, the sighing, the distended veins, prove the existence of a highly asthenic state. The absence of internal mortification shows, that if the disease becomes putrid, it is when long protracted.

In the cure, Dr. Rush, adopting the idea of its being inflammatory, bled largely and repeatedly; he adds with success. But were his success so conspicuous, his brethren would not probably have so strenuously urged an opposite plan; nor would the relations of the patients screamed with terror when the bleeding was proposed. This he tells us has often happened. Though we consider Dr. Rush, however, as the slave of prejudice and system, we believe him to speak what he thinks; and we can easily suppose that early bleeding in the manner described may have been useful. We know that Sydenham bled in the plague, and Dover in putrid fevers; we know, too, that other practitioners in the West Indies have bled in the yellow fever with advantage. The bleedings must however be large, and confined to the first twenty-four, or at most thirty-six hours. Dr. Rush at first extended the period in which this remedy might be proper, but in the following epidemics was more cautious. It is not necessary to assign a reason for the utility of bleeding, though we can perceive some foundation for the practice. When in asthenic cases the blood is determined to the larger vessels, if these are not excited to action by the distention, they become still more torpid. Lessening actively the

general mass relieves the over distended torpid vessels in a greater degree than the loss of blood weakens the whole system: their action commences, and the salutary discharges are induced.

To fulfil the other indications may appear an easy task; the stomach and bowels are to be emptied, the bark and wine given, and the whole is at an end. Such is the easy track of the theorist. In practice, however, we find the stomach so highly irritated that we dare scarcely add to the irritation. To assist the vomiting with mild, diluent, nutritious fluids, as mutton and chicken broth; or, if the urgings are violent and ineffectual, to aid them with a small dose of ipecacuanha, or tartarised antimony, is all that can be allowed. We have already remarked, that all neutral salts possess an anti-emetic power, and a dilute solution of these with manna and tamarinds may be drunk frequently to evacuate the bowels. Some physicians have added a small proportion of tartarised antimony; and this medicine, in the dose of one-sixth or one-eighth of a grain, will sit easily on the stomach, and tend rather to produce a discharge downward than to vomit. In some instances where the vomiting and diarrhoea are dangerously violent, a slight opiate may be given to regulate rather than repress them.

When a sufficient discharge is procured where necessary, or regulated when excessive, warm cordials may be safely employed to support the strength; and wine cautiously given, observing its effects, and from these directing its repetition or omission. The discharge by stool must be kept up according to the symptoms and the nature of the evacuations. Respecting the cordials and tonics practitioners have differed: the bark irritates the stomach and bowels, and can seldom be retained. When it is so the effects have not often been salutary. The contrayerva and serpentaria have been employed; but the disease treated by Hillary and Lining seems scarcely to have been the violent fever, which has so lately forced itself on our attention, and animated our exertions. The columbo root may be useful in correcting putrid bile, but it has a very inconsiderable effect as a tonic. The quassia is by far more serviceable, and the cascarrilla has been employed with advantage.

Practitioners have greatly differed respecting the propriety of applying blisters. The discharge from these is thin, acrid, and yellow; nor have they been seemingly of any utility. Indeed they are not apparently indicated in any stage of the fever, except from the affection of the head, which is rather a mark of debility than of fulness. Theoretical views have occasioned the discussion rather than observation of their effects; and their power of attenuating the blood, of which there is not the slightest evidence, has been the chief subject of dispute. Acrid cataplasms to the feet have not been more useful; and the warm bath, though often employed, seems to have done little service. The whole plan of cure consists in evacuating the stomach and bowels with the least irritation, and supporting the force of the circulation.

Two other plans have engaged the attention of practitioners. The followers of Brown, with the rashness and indiscriminate violence of sectaries, urge their tonic plan of cure, and give at once the warmest stimulants:

If the view we have given of the disease be correct, we need not say with what success over distended vessels are thus excited to transitory and ineffectual action. In fact they have been very unsuccessful.

The second plan is that, we believe, now generally followed, viz. the mercurial. Calomel unites the different objects, since it not only evacuates the alimentary canal, but effectually stimulates the vessels of the biliary system, and supports the action of the smaller vessels. When the bowels are so irritable as not to bear its being given internally, frictions of mercurial ointment will supply its place. This practice is not yet unquestionably established, but it is rapidly gaining ground, and promises to be highly useful. The mercury must be introduced as usual into the system, until some sign of its action on the minuter vessels is observed.

The late fever in Spain and Gibraltar showed the same marks of asthenic venous accumulation, with a similar affection of the biliary system. We cannot perceive, from the very accurate description in one of the last volumes of Dr. Duncan's Annals, that it had any very peculiar or discriminating marks to distinguish it from the yellow fever of America. Nor have we found a single improvement in the conduct which requires a detail.

See Bisset on the Bilious Fever of the West Indies. London Med. Obs. and Inq. vol. iv. p. 156. Blicke on the Bilious Fever of Jamaica. Sir John Pringle, Drs. Chalmers, Lind, Towne, Warren, Cleghorn, and Rouppe. Of the more modern authors Dr. Rush, Dr. Chisholme, Drs. Mosely and Grant, merit the most considerable attention.

BILIS. In Ainsworth it is derived from *φαιλος*, scil. *succus, juice*; and also *fel, bile*, or *gall*; and we know no better etymology.

It is a bitter viscid juice, secreted from the blood in the liver, and collected in the receptacle known by the name of gall bladder. The blood collected from the adjacent abdominal viscera is thrown into the *vena portæ* in the liver, from whence it is secreted. When formed, it is carried to the beginnings of the biliary ducts, called *fori*, or more properly *tubæ bilariæ*, and by them is conveyed into the ductus hepaticus. This duct, passing on a little way, enters into the ductus communis chole-dochus, whence the *bile* is partly discharged into the duodenum, partly regurgitates into the ductus cysticus, and falls into the gall bladder. By lodging there some time its thinner parts transude, or are reabsorbed, and the rest becomes thicker and more acid; increases in bitterness, and the depth of its colour.

The hepatic *bile* before it is mixed with the cystic is subalkaline and rather oily; it continually passes into the duodenum, but the cystic only when required.

The *bile* is formed from the blood in the secretory vessels of the liver. It is of a yellow colour, varying to green; has a bitter taste, with something like sweetness; the mucilage which it contains is decomposed, not coagulated by acids, and some of their compounds; the acids precipitating only a part which is resinous. It is soluble in alcohol, but incompletely. It has a peculiar smell of the species of animal in which it is produced, and is a powerful antiputrescent. Dr. Saunders, from some experiments, draws the following conclusions respecting the elements forming the bile, and says it con-

sists, 1st, Of water impregnated with the odorous principle. 2dly, A mucilaginous substance, resembling the albumen ovi. 3dly, A resinous substance, containing the colouring principle and bitter taste. 4thly, A mild mineral alkali. With respect to their combination, it seems that what has been styled the saponaceous matter consists of the bitter resin in union with the alkali; this admits of a ready union with a mucilage, and with this again the aqueous matter very easily combines, so that the whole forms an apparently homogeneous mass. The soap, or the saponaceous matter of the bile, is equally soluble in water and alcohol.

It is the least putrescent of any fluid in the body; its apparent use is to mix the chyle, to support the peristaltic motion of the intestines, and to assist in completing the assimilation of the food. When the stomach is full, the cystic *bile* is more copiously discharged into the duodenum; when it is empty, the hepatic more freely into the gall bladder.

The odour of the bile is nauseous, though when evaporated or spontaneously decomposed resembling that of musk, an odour which at times the perspirable matter, if confined, will also exhale. Its specific gravity to that of water is 1.0246 to 1.0000. It is perfectly soluble in water. Acids separate the soda and the coagulated albumen; and the bitter inflammable matter, styled the resin, is left in the filter. The sulphuric acid gives the bile a deep green colour; concentrated nitric, a brilliant yellow; and the muriatic, a beautiful clear green; oxygenated muriatic acid destroys the colour of the bile, and coagulates its albumen, which it precipitates, furnishing the albumen seemingly with oxygen. The colourless bile, however, still contains an oil, though changed by the oxygen, so as to be soluble in water. This oil is precipitated by an acid, and consequently the fluid still seems to retain a portion of soda. Bile contains also a white crystalline matter, which sometimes contributes to the formation of biliary calculi, but it differs greatly from the white oil, since it is more soluble in alcohol, and not precipitated in laminæ. The oil also is as fusible as fat, but the laminæ require a heat exceeding that of boiling water.

When putrified in a considerable heat, its odour is more nauseous; its colour changes; white mucilaginous flocks are precipitated; and it becomes more fluid. When putrefaction was further advanced, the smell became more pleasant, resembling that of ambergris. From inspissated bile kept a long time without decomposition, the musky odour may be obtained by distillation, combined with the water. The coal remaining after distillation contains carbonat of soda, phosphat of lime, and a small proportion of oxid of iron. Fourcroy adds a small proportion of prussic acid, to which probably the bile owes its bitterness; but this part of the subject we shall soon again notice. The saponaceous nature of the bile has occasioned many disquisitions and disputes. It is, undoubtedly, not a soap in the strict chemical sense of the term, though approaching a saponaceous nature; but, as on this point no physiological question hinges, we need not enlarge on it.

Various authors have supposed that bile exists already formed in the blood. Mr. Higgins, in his Comparative View of the Merits of the Phlogistic and Anti-

phlogistic systems, describes some experiments on the blood, in which a yellow matter not unlike bile was separated: and Fourcroy, by a more complicated process, has changed the blood into a fluid resembling bile. Yet, in the economy of the animal system, in all its subordinate gradations, there is no organ more constant than the liver, no apparatus of secretion more complicated than that for preparing bile. In the human body, the blood designed for this purpose, has already circulated, without being again exposed to the atmospheric air, so that it is deoxygenated; but the fluid itself resists rather than promotes putrefaction, nor do we find it on experiment highly azotic. The bile, it is said, neutralises acids; and, as in children it is thin and watery, authors have supposed that it performs its office imperfectly, and that for this reason acids abound in their stomachs. Bile, however, never passes naturally into the stomach, and when there produces considerable inconvenience: on the other hand, though acid may be prevalent in the stomach, it does not appear beyond the duodenum, where the contents of the stomach meet with the bile. One of its use is, therefore, very probably to correct acidity.

Its saponaceous nature was said to assist the union of the oil and water in the formation of chyle; but this idea is effectually destroyed by the experiment of Dr. G. Fordyce, who tied the ductus choledochus communis, and still found the lacteals filled with a chylous fluid.

The ancients supposed the liver to be the organ by which the nourishment was prepared; and Fourcroy has lately endeavoured to revive the opinion, supposing that the long protracted circulation was destined to unite more intimately the molecules of the blood with the new nourishment, with the air taken in by the lungs, and that formed during the circulation. When we reflect on the general importance of the liver, and that its place cannot be supplied by any other organ; when the emaciation which follows its diseases, and the immense size to which inactivity with highly nutritious food enlarges it, this idea will appear to have greater force. Yet we think it acts only, in this respect, a secondary part. We shall find, in our enquiries into the process of digestion, a very great change produced by it on the food taken in; an immense distance between, for instance, the herbage of the field and the muscular fibres of the sheep and ox: we shall, of course, perceive the necessity of a powerful agent for the production of this change. A fluid highly animalised, is necessary to join the vegetable matter before it is permitted to mix with the general mass; for the mildest chyle immediately injected into the vessels is fatal: and this matter must be very distant from a putrescent fluid, since this process, already going on in the sanguiferous system, requires a check rather than a ferment. It is then a fluid necessary for perfecting the assimilation of the aliment, and giving to the chyle some principle which enables it to join the general mass with impunity. We consequently see it formed from blood which has undergone a languid circulation, but not from those parts where it might meet with a putrid fomes; for the hæmorrhoidal veins do not form a portion of the vena portarum. This blood is said by some authors to be peculiarly fluid; it probably contains a larger portion of soda, with hydrogen and carbone. The two latter, in consequence of the languid circulation uniting with

the remaining oxygen, form with the fibrin of the blood the oil, which is rather a spermaceti than a truly oleaginous fluid. In those animals whose respiratory organs are small, the liver is unusually large; and we find birds, whose livers are naturally small, when pent up in a close coop, have this gland considerably increased in bulk. When this oil abounds and the fluid no longer holds it in solution, a crystallization takes place, and biliary calculi are formed, of which we shall afterwards treat. See CALCULUS BILIARIS.

It is observed, in general, that the gall of small animals is stronger and more acrid than those of larger kinds; that the gall of carnivorous animals is more active than those of herbivorous. Instances are those of the hawk, serpent, eel, and pike, but in general all their secreted fluids are more acrimonious.

Physiologists have warmly contended, whether the bile was derived from the hepatic artery or the vena portæ. But, as the former artery is small, as its ramifications are not peculiar, and as the circulation in the latter is singularly complicated, and has no apparent object but the preparation of a very important fluid, it is generally supposed that the hepatic artery only nourishes the viscus, while the secretion is exclusively from the contents of the vena portæ.

The changes of the bile from disease are not numerous, but merit particular notice. We have introduced the appearances which putrefaction really occasions, to show that this state of the bile is often accused, when in reality it does not exist. The dark acrimonious bile is often a depraved secretion; and the dark flakes in bile are equally produced by a derangement in the functions of this organ. These are generally the result of too great indulgence in spirituous liquors. Bile will sometimes assume so dark a hue as to be mistaken for blood. Dilution destroys the error; for the diluted fluid has a yellow tinge; and the flakes, to which this dark colour is often owing, are then obvious. With acids the bile assumes a greenish colour; and, as bile when in the circulating system is soon carried to the kidneys, we once saw it convey this green hue to the urine. The cause was evident, since an alkali destroyed it. Another disease of the bile is an oiliness; in other words, the adipocire becomes a more perfect oil, which the soda does not unite to the watery part of the fluid. It is often vomited in this state, and is the strongest proof of a considerable injury experienced in the process of digestion. The defect of bile is known from the white colour of the stools; but more certainly from the appearance of bile in the urine and under the skin. We see occasionally the kidneys torpid from a paralysis of the renal vessels, but we recollect no instance of a want of bile from the same cause. Fernelius, in his Pathology, speaks of a defect of bile as producing different diseases; but he means rather an obstruction, and that kind which is owing to a scirrhus liver.

In fevers the bilious discharges are often copious and troublesome; and the liver is the organ generally affected when the fluids are not propelled to the surface, since its vessels chiefly contain the blood from the venous system. Yet copious discharges of bile are peculiar to remittents and intermittents, though in continued fevers of every kind the liver is unusually filled—

in medical language infarcted—and peculiar attention to the discharge of its contents is required.

According to the supposed uses of the bile has it been employed as a medicine. It is a saponaceous aperient, a stomachic, a laxative, or a tonic, if the opinion of the author is in favour of either system. When the bile is deficient, it has been supplied with that of the ox; the practitioner forgetting that bile in the stomach was the source of numerous inconveniences, particularly sickness, faintness, and cold sweats. It has, however, been fortunately given in pills, and escaped the stomach without greatly disordering it. That bile is a stimulus to the action of the intestines is more probable; yet in jaundice we have not found costiveness peculiarly prevalent, and it seems to have been marked as a symptom rather from theory than observation. Inspissated bile of oxen has been given to children in a dose of one grain, and to adults in three or four, three or four times a day, to relieve visceral obstructions, to promote urine, and the menses; or half a drachm has been administered in clysters. If this has not succeeded, Boerhaave recommends the gall of the eel or pike; and remarks that the hard bellies of rickety children have been relieved by these remedies. We cannot doubt the utility of such an acrid fluid; but the small proportion of an ox's bile above recommended can have very little effect. If it has any, we cannot think that it would be a salutary one. In jaundice it has been given to supply the defect of bile; but modern practice disregards it, and we cannot speak of it from experience. On recurring to those authors who have recommended it, we find those vague and general praises which in similar circumstances we have had so much reason to distrust.

As putrid, acrimonious, and copious discharges of bile from the intestines are so often accused as causes of disease, when in reality they are only effects or symptoms, so in the stomach it is often supposed to be injurious, when brought by the medicines intended to discharge it. When bile is suspected of producing inconvenience in the stomach, and an emetic is given to discharge it, we often find no bile evacuated, but the next food or medicine brings it up; in fact the fluid, which the emetic, by inverting the action of the duodenum, had brought into the stomach.

A too copious secretion of bile sometimes occasions inconvenience, and in this case the alternation of laxatives and opiates removes the cause of complaint. We have thought that opiates really check the secretion of bile; but as any stimulus on the mouth of the opening of the ductus communis will increase the discharge, opium may act only by diminishing its too great sensibility and irritability. We may just add, that, in judging of the pains occasioned by accumulations or obstructions of bile, we must recollect that the under edge of the gall bladder, and the entrance of the biliary duct, are nearly at the pit of the stomach; the pain is felt there when a stone enters the duct, and a fulness is perceived in that part when there is an accumulation of bile. The course of the duct is then backward; and when the stone is near the extremity of the duct which opens into the duodenum, the pain is felt on the opposite side at the back.

Essays. The Appendix to Sir John Pringle's Diseases of the Army. Maclurg on the Human Bile. Coe on Biliary Concretions. Saunders on the Structure, Economy, &c. of the Liver; and Fordyce on Digestion. Fourcroy Système de Connoissances Chimiques. Cadet Experiences Chimiques.

BI'LIS A'TRA. See ATRABILIS.

BI'LLING-BING. See BILIMBI.

BINA'RIOUS, (from *binus*, double). Among the Romans it is the number two. But the Spagiric philosophers affix other ideas to it. See Théât. Chim. vol. i.

BINGA'LLI. See CASSUMUNAR.

BINO'CULUS, (from *binus*, double, and *oculus*, the eye). A bandage for retaining the dressings on both eyes. It is either a single or a double headed roller, is twelve feet long, and two or three fingers in breadth. Its application will be easily understood by referring to MONOCULUS.

BI'NSICA. A Rabbinical term signifying *mental sickness*, or a *disordered imagination*. By the addition of MORS to this term, it is a BINSICAL DEATH; the death which follows the disorders of the mind, such as are produced by the bite of a mad dog.

BINTA'MBARU ZEYLANE'NSIBUS. (Indian). *Convolvulus maritimus Zeylanicus*; *pes capræ Lusitaniae*; the *convolvulus pes capræ* Lin. Sp. Pl. 226. A plant growing in Malabar and Ceylon; it abounds with an acrid milky juice. A drachm of the resin of the root purges. Raii Hist.

BIOLY'CHNIUM, (from *βίος*, life, and *λυχνιον*, a candle or lamp). The LAMP OF LIFE. Vital heat, vital flame, or natural heat. See CALIDUM INNATUM. It is also the name of a secret remedy prepared from human blood by Beguinus.

BI'OS. (Greek). Life and its course. But sometimes it only means victuals.

BIO'TE, (from *βίος*, life). LIFE. In an affected sense it signifies the time of a continuance of aliment in the body; thus weak food hath a short life annexed.

BIO'TH'A'NATI, (from *βίαι*, violent, and *θανάτος*, death). A term applied to those who die a violent and sudden death; it is sometimes applied to suicides.

BIPIN'ELLA, and BIPEMULLA. See PLANTAGO MINOR, and PIMPINELLA.

BIPULA. A worm mentioned by Aristotle.

BI'RA. See ALLA.

BIRA'O. See AMOMUM.

BIRD'S NEST. The nest of the *hirundo esculenta*. See ALIMENT.

BIRE'THUS, (from *βίβλος*, a priest's hood, from its resemblance). See CUCUPHA.

BI'RSEN. An Arabian or Persian word, signifying an inflammation or imposthume in the breast.

BIRTH. A term in midwifery. It is styled *natural*, when the head presents; *premature*, when at too early a period; *preternatural*, when any part but the head presents; and *laborious*, when from obstacles or weakness it is protracted. See LABOURS.

BIRTH WORT. See ARISTOLOCHIA.

BISCO'CTUS, (from *bis*, twice, and *coquo*, to boil). TWICE DRESSED. This word is chiefly applied to bread twice baked, or that is much baked; i. e. BISCUIT.

BISCUIT, SEA. This is doubly baked; but its excellence consists in its not being fermented, and consequently not easily becoming acid in the stomach. It

is on this account more fit for children, and those troubled with acid in the stomach. These biscuits may be long kept; and the rusks, which are also twice baked, have the same advantage, but are not equally useful with the unleavened biscuit in diseases. See BREAD.

BISEMATUM. See PLUMBUM.

BISLINGUA, (from *bis*, twice and *lingua*, a tongue,) so called from its appearance of being double tongued, or of having upon each leaf a less leaf. See LAURUS ALEXANDRINA.

BISMALVA. Supposed to be a corruption of the word *vismalva*, quasi *viscum malva*, from its superior viscosity. V and B were convertible letters, and hence this line of Scaliger:

‘Felices populi quibus vivere est bibere.’

See ALTHEA.

BISMUTHUM, (from *bismut*, German). BISMUTH; also called *wismuthum*, *marcasita*, *Galena inanis*, *plumbum cinereum Agricolaë*, *blende Germanis*, MARCASITE OF SILVER, and TIN GLASS.

It seems not to have been known to the Arabians, for their *marcasita* was the lapis pyrites; and the first traces of it occur in Basil Valentine. It is a brittle metal of a silvery whiteness; of the specific gravity 9.8217, melting at 460° of heat, smoking, and in a more intense fire rising in fumes. If calcined in close vessels the calx is in part volatile: if agitated it grows yellow, next red, and soon becomes a glass, vitrifying with it some of the less perfect metals. It may be easily powdered. The nitrous acid dissolves it, from which it is precipitated in the form of a bright white powder by dilution with water. The marine acid does not readily affect it, and the vitriolic scarcely at all. It impregnates the vegetable acid with a nauseous taste, and from all the acids may be separated by water alone in the form of a milky calx. By zinc and iron it may be precipitated in a metallic form. The chief of it brought into England is from Saxony. Dr. Alston denies that the ores of bismuth contain any arsenic; it is true that the bismuth, when brought to us, is without such particles.

It mixes easily with several metals, but destroys their ductility. It promotes the fusion of other metallic bodies. Mixed with lead and tin it forms a compound that melts with a very small heat; the following proportion is so fusible that it hath been proposed for anatomical injections, two parts of lead, three of tin, and five of *bismuth*. If *bismuth* is mixed with lead, a larger portion of the latter can be combined with quicksilver than without this method; and the quicksilver cannot be by the common methods.

The magistry of bismuth is a precipitation of the calx from nitrous acid by means of water, and with the addition of powdered pearls. It is styled *pearl white*, and chiefly used as a cosmetic. Internally, it has been said to occasion great anxiety. Dr. Odier has, however, recommended it in hysteric colics, diarrhœas, and all diseases owing to too great irritability, particularly in the violent pains arising from a scirrhus of the pylorus. Carminati of Pavia, and Bonnat in France, have also experienced its good effects in similar diseases. Dr. Odier found it serviceable in the toothach. The dose is one or two grains suspended by mucilage, gradually increased to six, and by Odier to twelve, four or five times in a day.

The SPANISH WHITE is a magistry of *bismuth*, made by dissolving it in spirit of nitre, and precipitating it with salt and water. The calx further calcined has been commended by Jacobi, but not employed by any of his successors for more than a hundred years.

BISTA'CIIUM. See PISTACIA.

BISTORTA. BISTORT: quasi *bis torta*; twice twisted, or wreathed. So called from the contortion of its roots. Called also the GREATER BISTORT, or SNAKE-WEED; *colubrina*, *beadiramon*. It is the *poligonum bistorta* Lin. Sp. Pl. 516. Nat. order *oleraceæ*.

It is perennial, a native of Britain, grows wild in moist meadows about Battersea, and by the side of Bishop's Wood near Hampstead, and flowers in May and June.

The root is bent vernicularly, and jointed at each bending. It is commonly about the thickness of a finger, surrounded with bushy fibres, of a blackish brown colour on the outside, and reddish within. It is distinguished from the other *bistort* roots by being less bent; that of the officinal species having only one or two bendings, and those of the other three or more.

This root is powerfully astringent, and as such antiseptic. It is of a singular efficacy in hæmorrhage, obstinate fluxes, looseness of the teeth, spongy gums, and soreness in the mouth. It is said to be refrigerant; but this is from its being antacid, whence all astringents are cooling. The dose is from gr. x. to ʒ i. Water totally dissolves its astringent matter. Extracts made with water, or with spirit, retain all the styptic qualities. All the parts of this plant possess the same qualities as the root, but in a less degree. If the roots are boiled in vinegar, an excellent antiseptic gargle is obtained. Dr. Cullen says it seems to be one of the strongest of our vegetable astringents, and justly commended for every virtue that has been ascribed to any other: he has frequently employed it in intermittents, and has given it both by itself and with gentian to the quantity of three drachms in one day. Cullen's *Materia Medica*.

The tormentil root is so similar in its efficacy, that it may always be substituted for it.

BISTOURY. In surgery is a small knife, either straight or crooked, single or double edged, round pointed or probe pointed. Its form must be regulated by the purpose for which it is employed. Sometimes a director or a grooved canula is employed, along which the knife passes; and at others the instrument is concealed in a kind of sheath, which supplies the place of a director, and raised at the moment it is to be employed.

BISUL. An abbreviation of BISULCIS, (from *bis*, twice, and *sulcus*, a furrow,) cloven footed.

BITHINOS. The name of a plaster described by Galen.

BITHNIMALCA. A word coined by Dolæus to signify a peculiar acting principle residing in the stomach, and presiding over the functions of digestion and chylication; called also *gasteranax*.

BITHYNICI TONSQ'RIS EMPLA'STRUM. The BITHNIAN BARBER'S PLASTER for splenetic people. See *Ætius* Tetrabib. iii. serm. ii. cap. xxii.

BI'TI. (Indian.) A tall evergreen tree in Malabar, and other parts of the East Indies. An oil is prepared from its root to cure the alopecia.

BI'TTERN. The oily fluid left after the crystallization of salt, styled the mother water, *eau mère*, since

no other salt will crystallize in consequence of the viscosity of the fluid, arising from the oily matter, occasioned by the decaying fish molluscæ and alga. It consists chiefly of vitriolated magnesia, and from it the Epsom salt is now prepared.

BITTERS. See AMARA.

BITTER ALMONDS. See AMYGDYLA.

BITTER GOURD, or APPL. See COLOCYNTHUS.

BITTER PURGING SALT. See SAL CATHARTICUM AMARUM.

BITTER SWEET. See SOLANUM.

BITU'MEN, *πίττωμα*, (from *πίττω*, *pitch*; or *πίττωμα*, from *πίττω*, a *pine*, because it flows from the pine tree,) called also *asphaltos*, *pisasphaltus*, *asphaltum*, *bitumen Judaicum*, *carabe funerum*, *gummi funerum*, *mumia*, CARABE OF SODON, FOSSILE PITCH, and JEWS' PITCH.

It is a solid mineral substance, of a dusky colour on the outside, and a deep shining black within; having but little taste or smell, except it is heated, in which case it emits a strong pitchy odour. It is not soluble in oils, nor in vinous spirits; it melts but imperfectly in the fire. On burning it a large quantity of ashes remain. It is found in the earth in many parts of Egypt, and floating on the surface of the Dead Sea. At first it is soft, but grows hard by keeping.

Though we have spoken of bitumen as a single substance, we are, from the labours of Mr. Hatchet and Mr. Kirwan enabled now to be more correct and discriminate. Bitumens are either fluid or solid. Of the former we have the pure naphtha and petroleum: of the latter, the mineral tar and pitch, and asphaltum. The first by exposure to the air gradually becomes darker, till from naphtha it is changed to a true asphaltum, the substance to which the synonyms at the head of the article apply. The amber is a bituminous substance also, though from a different source.

Bitumens, like oils, are composed of hydrogen, carbon, and azote, modified in some measure by oxygen. To carry on the analogy with the substances of the vegetable kingdom which they resemble, we may suppose the two extremities of the scale, naphtha and asphaltum, to be the ethereal oils and resins. It is indeed highly probable that all bitumens are of vegetable origin (Hatchet, Phil. Transactions, for 1805, part ii. and Nicholson's Journal, vol. ii.). *Naphtha*, the purest of the bitumens, is lighter than water, viz. 0.788: the smell highly penetrating, though not disagreeable, like oil of amber. It resists the cold of 0 of Fahrenheit. The petroleum is less fluid, transparent, and agreeable, specific gravity 0.878. *Mineral tar*, dark coloured, viscid, and of an unpleasing smell; scarcely if at all heavier than water. *Mineral pitch*, brittle in cold weather, dark and opaque; gravity nearly that of water. *Asphaltum*, very brittle and shining, fusible and inflammable, specific gravity often 1.165.

These seemingly differ only in their proportion of oxygen. In medicine, the first kind has been employed as a stimulant and an antispasmodic, but is now disused. It is employed externally only in chilblains and paralytic affections: and what is styled British oil is drawn from stone coal. Naphtha has been employed in hecetics, but is too stimulating, and produces considerable inconvenience. It is found very pure, near the Caspian Sea, at Backu. See PETROLEUM and SUCCINUM.

BITU'MEN BARBADENSE. See PISSELEUM.

BITU'MEN LIQIDUM. See PETROLEUM.

BIVE'NTER. Thus muscles are named that have two bellies, from *bis* and *venter*; also *digastricus*.

BIVE'NTER MU'SCULUS. It arises from the processus mastoideus. Its tendon frequently joins the stylohyoideus and the membranous ring fixed to the os hyoideus, and is then attached to the inner part of the chin. It depresses the jaw, and thus opens the mouth. It is fleshy at both its extremities, and tendinous in the middle. The middle tendon passing through the aponeurotic ligament as the lateral part, and the root of the cornua of the os hyoides, is what renders it capable of performing its office. The ancients called it *graphoides*.

BIXA OVIEDI. See ACHIOTL.

BIXA ORELLANA. See ORLEANA.

BLACCIE. See MORBILLI.

BLACK VO'MIT. The discharge from the stomach in the last stage of the yellow fever. See BILE.

BLA'DDER. See VESICA URINARIA.

BLÆ'SITAS, (from *blasus*). See PSELLISMUS RINGENS.

BLÆ'SUS, *βλαιστός*, (from *βλαπτω*, to injure). The same as *valgus*, BANDY LEGGED, or one whose legs are bent outward, called also *cyllos*, *devalgatus*: one whose back bone is bent either forward or backward; also a paralytic person, and one who hath an impediment in his speech. Blancard.

BLA'NCA, (from *blanc*, French, *white*). See PLUMBUM. Also the name of a purging medicine in the Antidotarium of Nicolaus.

BLANC TA'RBE. See COBALTUM.

BLA'NCNON. See FILIX.

BLAS'A. An Indian name of a tree, the fruit of which, when powdered, is given to destroy worms. Raii Hist.

BLAST. A vulgar term for inflammation; quasi *blasted*, *burnt*, as trees from the influence of lightning.

BLASTE'MA, (from *βλαστειναι*, to germinate). Also called *germen*. A BUD, OFFSET, or SHOOT of a plant: but Hippocrates expresses by it a cutaneous eruption or pimple.

BLATTA, (from *βλαπτω*, to hurt; so called from its injuring books or clothes,) or BLATTA FÆTIDA. The SLOW-LEGGED BEETLE, or BOOK WORM. It is that species of beetle which is so common in bake houses. If they are boiled and bruised in oil, then dropped into the ear, they are said to relieve pains in that part.

BLATTA'RIA LUTE'A, (from *blatta*; so called because it engenders that reptile). YELLOW MOTH MULEIN. It is said to possess the same virtues as the *verbascum*, but merits no particular notice.

BLA'TTI, *sonneratia acida* Lin. Supplem. 252. Willdenow, vol. ii. 999. The seeds are surrounded by an acid juice, and the fruits are dressed as alimentary substances. The leaves are applied to the head to relieve vertigos, and their juice is supposed useful in aphthæ.

BLEEDING. See PHLEBOTOMIA.

BLE'NDE. A German name for BISMUTH. See BISMUTHUM; ZINCUM.

BLE'NNA, or BLE'NA, (Greek, *mucus*). A thick phlegm descending from the brain through the nostrils.

BLE'NORRHAGIA, and BLE'NORRHŒA, (from *βλεννος*, *mucus*, and *ρεω*, *fluo*). A newly formed genus of disease, to supersede the probably too general use of catarrhus. It is intended to include the mucous

discharges, but it should have been confined to those from the genital and urinary systems.

We shall divide them into discharges from venereal, from miscellaneous acrimony, and from relaxation. For the first, see GONORRŒA. The acrimony we have styled *miscellaneous*, may be any internal irritation, the stimulus of cantharides, or some other poison; gouty irritation, calculus, and cancer. See STRANGURY and CANCER.

The blenorrhœa is attended with very slight, if any, inflammation; though this may be occasionally excited by free living, riding on horseback, excess of venery, or either of the former acrimonies. But, except from the venereal poison, this superadded inflammation is transitory. The discharge may occur from any part of the urinary or genital organs. See GONORRŒA BENIGNA, LEUCORRŒA, CATARRHUS VESICÆ.

BLEPHARA; quasi, *βλεπουσ φαρος*, as being the cover or defence of the sight. See PALPEBRÆ.

BLEPHARIDES, (from *βλεφαρον*, an eye lid). The hairs on the edges of the eye lids; also that part of the eye lids themselves on which the hairs grow.

BLEPHAROPTO'SIS, (from *βλεφαρον*, *palpebra*, eye lid, and *πτωσις*, *casus*, descent,) called also *ptosis*. A dislocation, or displacing of either, or BOTH EYE LIDS, by elongation, retraction, turning inwards or outwards, with different symptoms in different species. But the true blepharoptosis, or preternatural descent of the eye lid, arises from a wound of the frontal muscles of the temple, or the superior levator of the eye lid, or from any large tumour dragging down the eye lid; from inflammatory or cold defluxions elongating the palpebra; from mere relaxations of the eye lids, or from a palsy of the palpebra, which is sometimes constant, sometimes periodical. See PTOSIS.

The varieties of this species are obvious. With respect to the first it must be remarked, that the cheek of the same side, the lower jaw, the tongue, eyes, and other parts, are affected. The second and third varieties are cured by conquering the primary disease to which they owe their origin; to the fourth, corroborating spirituous fomentations are useful; to the fifth anti-paralytic remedies administered externally and internally. If these remedies do not properly succeed in the two last, a cure must be sought for from a surgical operation, performed on the prolapsed palpebra, or on the skin of the forehead. Internal remedies are scarcely useful; but such as will draw off the superabundant serous fluids, which are chiefly purgative and diuretic remedies, particularly jalap, and sal diureticus, may be employed. Amongst the remedies for any paralytic affection, electricity may be mentioned as occasioning the increased action of any particular muscle. In that variety said to proceed from relaxation, the use of alum with an infusion of oak bark is recommended for an external application; but if it does not succeed, the relaxed skin must be cut away, and the edges of the wounds confined together by sutures, and healed in that situation. There are several other species of this disease. See ECTROPIUM, TRICHIA.

BLEPHARO'TIS, (from *βλεφαρον*, the eye lid). INFLAMMATION of the EYE LIDS. See OPHTHALMIA.

BLEPHARO'XYISIS, (from *βλεφαρον* and *ξεω*, to *scrape off*). See OPHTHALMOXYSTRUM.

BLEPHARO'XYSTON, the RASP-LIKE PROBE. So

Paulus Ægineta, in lib iii. cap. xxii. calls the *specillum asperatum*, from *βλεφαρον*, an eye lid, and *ξεω*, to *scrape off*.

BLESTRI'SMUS (from *βαλλω*, to throw about). A restless tossing of the body, as in a phrensy.

BLE'TA, WHITE. An epithet for milky urine, proceeding from diseased kidneys.

BLETI, STRUCK. Those who were suddenly seized with a suffocation, or difficulty of breathing. Hippocrates applies the term to a livid spot on the chest, as if the person had been struck. It sometimes is observed in pleurisy.

BLINDNESS. This very comprehensive term includes a variety of very different diseases; and we must here consider not only imperfect or depraved vision, but the causes of the total loss of sight. Imperfect vision proceeds from many sources. We have noticed, in different parts of the work, that which arises from the rays of light converging before they reach the retina, or beyond it; the species occasioned by diseases of the lids, and obtusions or ulcers on the cornea; those which arise from opacity of the lens, and from a palsy of the optic nerve. Little therefore remains but to notice partial transitory obstructions, or imaginary appearances. In nervous diseases the sight is sometimes for a time lost; and though this deprivation occurs without danger, and is temporary only, yet we ought to reflect that it is often the forerunner of a fatal apoplexy or a palsy. The *muscæ volitantes*, as they are called, motes floating before the eye, and for a time obscuring the sight, are equally signs of an approaching cataract. Yet, after a strong light, or from transitory debility, they occur with little danger or permanence. There is another imperfection of vision from fulness of blood; and in this case the sight is obscured by lines, with apparent intersections. An author, whose name has escaped us, mentions it as an impression on the retina, from the passage of the blood through vessels not usually conveying the red globules. We remember the disease occurring in a man who could represent his sensations by a pencil. He drew the figures that appeared to him, and they formed an exact representation of the circulation of the blood, as seen through a microscope. Bleeding and low diet completely removed this complaint.

There are many imaginary appearances in the eyes, not only from fulness, but from nervous affections. Double vision is not uncommon: to see objects inverted is an occurrence not indicative of any considerable disease. False representations are generally morbid: to see angels round the bed, wild beasts with open mouths ready to devour, flames curling round and scorching, are the effects of fever, or an imagination greatly disturbed. The organ is not affected; but the impression on the sensorium is not consonant to that on the nervous extremities, or the associated idea is stronger than that from the impression.

Blindness is seldom complete. Strong lights are often perceived; the forms of objects not uncommonly: but the colour, the shade, and the minuter forms, are in many instances imperceptible. In this case every sense is alive to supply the imperfection. Spalanzani has shown, that a blinded bat can avoid objects in its way; and we know, from the blind people who can describe their feelings, that they can distinguish a

crowded from an empty room; one furnished from another unfurnished; windows opening to the country or a street; tall from short persons; and even in a theatre, an able and judicious actor from a pretender to the art. The feelings, the breathing, the hearing, in short, a combination of all the senses, almost a new sense, contribute to their information. It has been supposed that the blind can distinguish colours by feeling, but this is not true. We remember Dr. Moyes observing, that an old blind man was brought to him who professed to distinguish colours. He had been a dyer; but in his determinations he was often wrong, and when correct, was assisted by the smell. Dr. Reid, in his 'Geometry of Visibles,' endeavours to show what ideas a blind man would entertain of different objects, though with little success. People blind from infancy have been restored to sight; and we might suppose that from their observations much might be collected. We have, however, only two well authenticated instances of persons restored to sight, who never remember to have seen. One, the case so often quoted from Mr. Cheselden; the other, more lately, in the Philosophical Transactions by Mr. Ware. They unfortunately differ in many respects; but we must be allowed to hint our suspicions, that Mr. Ware's patient must have remembered seeing, for he knew a cloth on the table to be green. This indeed he might have heard, but he ascertained the distance: this a blind man could not have done. Had he in any instance been able to distinguish objects either from their brilliancy or their shape, this faculty might have been acquired, but in no other way. We remember seeing an account of the feelings of another person who never had seen, restored to sight by the extraction of a cataract, in the papers of an old surgeon. He could not distinguish distances; and when carried near a river, was eager to walk on that beautiful plain. The various resources for the amusement of blind persons, and their mode of assisting their acquisition of the different abstract sciences, are scarcely a part of our subject. Perhaps we have already strayed from it; but literally, in our situation, *nihil humani nobis est alienum*.

**BLISTERS.** The operation of this most useful remedy has occasioned numerous disquisitions and eager controversies. It is fortunate that the calm attentive practitioner has steadily pursued his path, and contributed to relieve or save his patient, without being influenced by the surrounding contests. As the principal application by which we excite blisters is the Spanish fly, the nature of this insect has contributed to keep alive the controversy, or to add to the difficulties. It will, however, make no part of our enquiry, and we must consequently refer to that article for some account of its peculiar qualities. See **CANTHARIDES**.

Blisters, when applied to the skin, first produce a tingling heat, a redness, and afterwards the cuticle is elevated, and a portion of fluid resembling the serum of the blood is inclosed, as in a bladder. When this is evacuated, a redness continues, the serum gradually thickens, at last becomes a whitish curdly substance, under which the new skin is again formed, or assumes a truly purulent appearance, and the blistered part contracts until the whole wound is healed.

From this very simple and confined operation, it is not, *à priori*, probable that extensive benefit should be

produced. The first effects are pain and irritation; and it was once supposed that blisters were only useful by their stimulant power. The evacuation followed; and others then thought that from this source only they were beneficial, and that their first effects were injurious. They were then antispasmodics from some unknown influence; they coagulated or thinned the blood according to the fancy of the pathologist; but the manner in which they really operate is still uncertain, notwithstanding the labours of Tralles in his closely printed quarto, entitled, *Usus Vesicantium*.

The first effect of blisters is undoubtedly stimulant; yet this stimulus is local, and seldom communicated to the whole system. In irritable skins, however, when the pain is considerable, when restlessness and want of sleep are the consequence, they are certainly for a time injurious from their stimulant power, but in general they relieve more pain than they give; they lessen previous irritation or uneasiness, and dispose to sleep. These are their effects in fevers and inflammations, where we might chiefly dread their stimulant power. It may be asked if they are never used as stimulants? Undoubtedly, but chiefly as local ones, and where we come near the affected nerve; and, indeed, from the moment of their application, they must be considered as such, though the external stimulus, relieving the internal, renders the former an object of little comparative importance. The great difficulty arises from considering the benefits derived from so small an external inflammation, when the internal, which it relieves, is so extensive and violent. Various have been the modes of resolving the question, and numerous the discussions which the various solutions have occasioned. The effects are undoubtedly disproportioned to the cause, but it is probable that the smallest relief given to the internal over distended vessels, gives nature an opportunity of exerting her powers, and the turgid arteries of propelling more effectually their contents. We shall not encumber this comprehensive account with the various theories of INFLAMMATION, or the different explanations of DERIVATION, but refer to these articles, q. v.

The stimulus of a blister seems also of service in lessening the excessive action of the nervous power. We well know that the tone and the sensibility of the nerves, and the consequent irritability of the muscles which they supply, are intimately connected with the state of the circulation in their extremities. We can easily see, therefore, the means by which this excessive action may be mitigated. In some peculiar circumstances, however, we have thought that diseases more purely nervous have been relieved by this remedy, and have suspected that there may be a balance between the excitement of the internal and external nervous power, as there more evidently is of the circulation. We need not enlarge on the subject, but leave this hint to suggest future enquiry. We may, however, add, that if blisters ever act as antispasmodics, it must be from this or a similar effect.

The discharge, in many instances, gives a greater permanence to the benefits derived from blisters, and in some cases seems to be the chief source of their advantages, particularly in dropsies, in humoral asthmas, the more decidedly serous apoplexies, and a few other diseases. It is continued, however, with some difficulty, as in many constitutions the blister rapidly heals, what-

ever be the application. The sabine ointment now generally supplies the place of the blister ointment, which is inconvenient by its effects on the neck of the bladder.

Though, as we have said, the inflammation is confined and slight, and the discharge inconsiderable, yet it probably has more effect on the constitution than we might suspect from the absolute quantity; for in many constitutions the continued discharge from blisters produces considerable debility: in some they can scarcely be borne for even the period of two or three days. We might attribute this to the quality of the discharge; but M. Margueron, who has analysed it (*Annales de Chimie*, vol. xiv.), found that it very nearly resembled the serum of the blood, containing only a little less of the albuminous portion. It is seemingly darker coloured from the tinge of the plaster, whose peculiar smell it retains. He found it the same when the blister was applied in putrid fevers, as when the person was in health.

Blisters have on many constitutions a cordial and exhilarating effect, generally on those of full habits, and probably of languid circulation, by relieving the over distended vessels. A gentleman, once highly distinguished at the bar, and of brilliant convivial powers, always applied a blister when he wished to shine in either sphere, and the effect was produced as soon as the warmth in the part began. We have heard also many, who even felt the pain of blisters acutely, declare that the relief of the languor they previously experienced, counterbalanced all their sufferings.

In our enumeration of the diseases benefited by blisters, we shall be guided by their effects, and shall consider them as altering the determination of the fluids from parts overloaded; influencing the determination of the nervous power; as stimulants, evacuates, and cordials.

In *fevers*, we generally find the equilibrium of the circulation greatly disturbed; and, in general, the two organs which chiefly suffer from over distention, are the brain and the liver. We have a more ready access to the latter by more easy remedies. The distention of the vessels of the brain is chiefly relieved by blisters. In some *inflammatory fevers* the load in the head is considerable; and in cases not truly phrenitic, the delirium is of that wild and violent kind which approaches very nearly to phrensy. When bleeding is admissible, it must be premised; and, in other cases, the stomach and bowels must be freely emptied. Blisters will then greatly relieve, but they should be applied very near the head, and in general immediately below the hair on the back part of the head. Near the head we have still the temples, as well as the parts behind the ears, for a succession of blisters, if necessary; since the first effects of this remedy are those most beneficial, and it is unnecessary to continue the discharge from one part more than thirty-six or forty-eight hours. We must still however look forward to the possibility of a continued determination; and should the fever not terminate in fourteen or sixteen days, shave the vertex, that cold applications may be employed, or any accidental scratch be healed, before it be necessary to apply a blister to that part. These frequent repetitions of blisters are however seldom necessary.

In the *typhus* there is also a determination to the head, though less violent, and with inflammation less active. In these our chief reliance is on blisters, for bleeding is improper, and active purging sometimes inadmissible. The inexperienced practitioner has been alarmed by the debilitating powers of this remedy; but these are observed in very few constitutions, nor have we ever found them permanently injurious in fevers of this kind. In the worst kind of asthenic fevers they are less proper; and in highly putrid fevers, they have been considered as rather injurious than useful.

The greatest advantages of blisters are experienced in *inflammations*. In *phrenitic cases* their administration does not greatly differ from that we have described, when speaking of inflammatory fevers. In *sore throats* we have mentioned them as highly useful, and they should extend from behind the ear under the lower jaw to the trachea. In every inflammation of the face they should be applied in the same way, and are highly useful. The *tic dolooureux*, in Dr. Fothergill's language, the *dolor faciei crucians*, is an exception to this rule, and indeed can scarcely be called an inflammation. In *inflammatory affections of the chest*, blisters are our chief dependance; and in every disease of this kind, except perhaps the putrid pneumonia, they are of service: in this, however, they are certainly not injurious, and, as we have said, they are not so in angina maligna. We spoke with less confidence of their effects in highly putrid fevers, as these have not very often occurred to us. In *inflammatory coughs* they are useful; and in many of these, especially if not attended with expectation, they seem to be more beneficial when applied to the bone of the neck, than to any part of the chest. In general, however, if there is any *fixed pain* in any part, to it they must be directed. To this subject, however, we must return in the articles of *PNEUMONIA* and *HECTIC FEVERS*. In *croup* we have said they are used, but, like most other remedies, with little advantage: and in *hooping cough* they rather guard against any inflammatory accumulation in the chest, than shorten or materially mitigate the disease.

In *inflammations of the abdomen* they are highly useful, with the exception only of those of the bladder; but even in the latter, when the inflammation is confined to its neck, a short application of a blister to the perinæum has been of service. In all *local pains* of the abdomen blisters will relieve, and we think they even facilitate the passage of a gall-stone through the duct. They are certainly useful in preventing inflammation of that part from the distention. In *gastrodynia*, whatever be the cause, they seem to relieve.

In all *inflammations of the joints* blisters are useful: even the paroxysms of *gout* they shorten and mitigate, though we have had reason to fear with disadvantage to the constitution. The *white swelling* is a peculiar disorder, which we cannot at present enlarge on. It consists however in its commencement of a rigidity of the ligaments, and in its progress of deep seated inflammation. In the early state, there is perhaps no more certain remedy than blisters repeatedly applied: their first action seems to be the most useful. Modern practitioners have substituted the stimulus of emetic tartar in these and some other swellings, particularly the bronchocele, it is said with success. In our hands,

however, it has appeared less useful; and the peculiar deep irritable little sores which it occasions soon prevent the use of this and every other external application.

In the *exanthemata*, we find blisters chiefly useful in *small pox* and *measles*. In the former, when the head and breast are greatly loaded previous to the eruption, they are often useful, and occasion a more mild and distinct kind. When repelled, also, they assist in their reproduction, and often prevent the inconveniences which arise from their disappearance. In *measles* they are more useful, on account of the violent catarrhal inflammation which often becomes pneumonic.

*Active hæmorrhages* are greatly relieved by blisters. The *sanguine effusions* in the brain producing *apoplexies* require their immediate application, without waiting for the effect of evacuations. *Bleedings from the nose and the lungs* are equally relieved by them. It has not been usual to apply them in discharges of blood from the bowels, chiefly perhaps because these are seldom of the active kind; and as it is not easy to ascertain the part, particularly affected, with accuracy. *Discharges of blood from the kidneys and bladder* also are not relieved by blisters. In *diarrhæas* from the *measles* they are supposed serviceable; and indeed this must be considered as an inflammatory complaint. In *dysentery* they are said to relieve pain, but are seldom employed.

Blisters are employed also to alter the determination of the nervous power. This is certainly a vague indication; but they are useful in *spasmodic pains of the intestines* when there is no inflammation; they relieve the paroxysms of *angina pectoris*, of *spasmodic asthma*, as well as *epilepsies* not connected with local *plethora* and *extravasation*; they remove pains in the stomach arising wholly from the irregular action of that organ; and coughs that are nervous and independent of inflammation. These are certainly facts, though the mode of their operation may be doubted.

Though the stimulus of blisters be transitory and local, yet they are certainly useful as stimulants. On the back part of the neck they stimulate the nerves sent to the throat, and relieve *aphonia*, and *deglutition* impeded from palsy. On the internal humerus they relieve *paralytic affections* of the hands and fingers; on the internal part of the thigh they are equally useful in weakness of the legs. They are certainly employed as stimulants in *palsy* and *apoplexy*, yet their power as such is doubtful. It is too much the custom to accumulate stimulants and evacuates in these emergencies till we know not to what the relief is to be attributed, and unfortunately to what our failure is owing, for the little remaining excitability is often thus destroyed. A gentle breath will re-illumine the flame, which a violent wind will irrecoverably extinguish. In *asphyxy*, in *carus*, in *cataplexy*, and in *hysteric affections*, which for a time apparently destroy life, they have been employed as stimulants; yet we doubt if with any good effect, except in the species *simulata*.

As evacuates we have already mentioned the good effects of blisters in *anasarca*, in *humoral asthma*, and in *serous apoplexies*; nor does our recollection at present supply any other disease to which from this power they are applied. In *tumours*, and *collections* of a doubtful nature, *setons* and *issues* are preferred. Where

the fluid to be discharged lies deeply imbedded, the two last are more useful.

We have mentioned the foundation of their employment as cordials. This rests, as we have seen, on a loose equivocal foundation; nor do we find them used by practitioners with this view, except in some cases of low nervous fever, in which their utility may perhaps be explained more satisfactorily by their power of altering the determination.

The inconveniences arising from *cantharides* have induced physicians to employ other stimulants with a view of exciting blisters. The flour of mustard, garlic, arum root, emetic tartar, and the vitriolic acid, have been used for this purpose. They produce, however, a very inadequate discharge, and we shall return to them under the title of *RUBEFACTANTS*. The only substance which may probably with advantage be substituted, is the inner bark of the *daphne mesereum* or *laureola*. The small branches are cut into portions of the required length, and macerated in warm water or vinegar till the bark can be loosened. This must be applied to the part previously rubbed with vinegar.

BLITUM FÆ'TIDUM. See *ATRIPLEX FÆTIDA*.

BLOOD. This is the fluid contained in the arteries and veins of the human body, and is generally red; but in some smaller vessels which will not admit the red particles, a fluid apparently similar in every other respect is contained, which should also retain the name. In the vessels of insects also a white fluid circulates, which, from the uniformity of nature, we may suppose to consist of similar component parts, but it is not styled blood; and such insects are generally denominated *exsanguineous*. Though we sometimes employ the distinguishing epithet *red blood*, yet this alone deserves the appellation, and to this we shall confine our observations.

From the period when philosophy began to investigate, with particular attention, the nature of the animal fluids, the blood has been a principal object. It has been tortured with all the violence of fire; but only since chemistry enabled us to examine satisfactorily the component parts of bodies, has its real nature been understood. The experiments of *MM. Parmentier* and *Deyeux* have illustrated the properties of this mysterious fluid more satisfactorily than those of all their predecessors.

The appearance of blood is well known. When drawn it has a peculiar faintish smell, which adheres more tenaciously to the coagulum than the serum. Like the aroma of vegetables its nature is little known. Its specific gravity is about 1090. It unites with cold, but is coagulated by boiling water, and by concentrated acids both vegetable and mineral, which change it to a dark brown. Mild alkalis, neutrals, and lime water, render it more fluid, and of a brighter colour. Vitriolated iron and copper coagulate it. Exposed to oxygen gas its colour is heightened, but the brilliant hue soon disappears, and the blood becomes black: after this change the oxygen has no effect. Exposed to unrespirable gas it becomes black. *Vasali* has informed us that the electricity of the circulating blood is positive; that of the excrementitious fluids negative. Blood at rest spontaneously separates into two parts, a red coagulum,

and a yellowish serum; unrespirable gas impedes, and oxygen accelerates, the coagulation. It coagulates more quickly when it flows slowly; and the coagulation is long protracted when the air is excluded. The blood of the catamenia seems never to coagulate. During the coagulation heat is extricated, seemingly from the coagulated part, as the increased temperature is not found in the serum. The coagulation is prevented by agitation; and when suffered to cool during the agitation, neither alkalis nor acids will afterwards coagulate it. In that state, alkalis greatly heighten its colour. In a day or two, at the heat of 50° of Fahrenheit, it becomes putrid, the coagulum softens, and soon disappears. It assumes the appearance of a dark coloured serum, with a few remains of coagula only; and the smell of ammonia is obvious.

Blood, when distilled, affords a large proportion of hydrogen, with carbonic acid gas and azote. The prussic acid also comes over, with insipid phlegm, empyreumatic oil, and an ammoniacal salt. The coal affords carbonat and muriat of soda, phosphat of lime, and oxid of iron.

When by less violence the different parts into which the blood spontaneously separates are examined, the *serum*, whose specific gravity is 1.0287, is found to be coagulated by the heat of 160°, into a tender tremulous clot, from which a glutinous fluid may be squeezed, styled the *serosity*. In fact, the serum appears to be a watery fluid containing albumen; and, when this is coagulated, the remaining water is squeezed out, with a small proportion of animal mucilage or gelatine. That gelatine was contained in the blood was generally doubted till ascertained by Fourcroy, and afterwards by Parmentier and Deyeux. It is confined, however, to the serum. Besides these substances, the serum contains carbonat and muriat of soda, phosphat of soda and of lime. The fixed alkali renders the albumen more soluble, and is apparently combined with it, as oil is in soap. The other salts are dissolved in the aqueous fluid.

There is one substance discovered in the serum, apparently peculiar to it, that we must notice particularly; we mean *sulphur*. We shall find it of considerable importance in the pathology of the animal fluids, and it is a principle whose source and existence are still obscure. If the albumen, perfectly dry, be heated in a silver vessel to a high temperature, it will be blackened; or, if triturated in a glass mortar with a fully saturated solution of silver, then digested, and afterwards diluted with water, some greyish threads will be deposited, from which sulphur, in the usual way, may be extracted. Again, if fixed alkali be boiled with the albumen and water, by adding distilled vinegar, a substance, whose smell is hepatic, and which discolours silver, will be deposited. Sulphur appears too in the white of an egg; it is found in the substance of the brain; but whether formally existing, or whether produced in the operation from its proximate principles, we cannot yet discover. We must rest, however, on the fact, that sulphur, in one of these ways, exists in the animal fluids. When in a larger proportion, or more copiously evolved, it will be found to press on our notice.

The existence of *gelatine*, as we have said, has been lately ascertained. On coagulating the serum, and suffering it to remain in the bath, a substance collects on

its surface, which was found by every chemical test to be jelly. Some portion of jelly is also, with great reason, supposed to remain combined with a part of the soda. The gelatine is, however, confined to the serum; and we have no reason to suppose that it varies in proportion or consistence in any known difference of the state of the constitution.

The *coagulum* is the next object of our attention, and it is in every view a very important one. The coagulation has been attributed to cold, to rest, and to the density of the liquor, but it is the effect of neither; and the chief, we believe the only, means of retarding it, is the addition of neutral salts. Various authors have mentioned the effects of Glauber's salts and muriat of soda; and we remember finding the same effects result by letting the blood flow into a solution of nitre without the slightest agitation. This experiment was made under the direction, and under the eye, of Dr. Cullen.

The coagulum does not soon lose its form or colour; but in a warm temperature is quickly deprived of both. If removed from the serum and placed in a water bath, its consistence is increased, and serum drops from it: if put in warm water, the fluid assumes a milky hue, and a scum arises on the top, both owing to the serum either dissolved or coagulated. In short, a portion of this substance accompanied the albumen with its attendant soda. The albumen, we must add, was found to be the portion most affected by disease. It separated sooner, and was less firm, but in no determined ratio to the violence or the nature of the complaint.

We have observed, that, in various experiments, some remaining thready substance, some unconquerable coagula, remained. In fact, dilution will prevent the coagulation of the albumen, but not of the portion we are next to speak of, the *fibrin* of the blood. It is thus styled because it concretes in fibres, and is found to be the most animalised portion of the vital fluid; that is, it contains the largest proportion of azote, and is even found to contract on the Galvanic stimulus. In short, when it has assumed the solid form, it resembles in every thing but in colour the muscular fibres; and it is a singular phenomenon to remark this intermediate step between a fluid and a solid, between matter in its common form and an organised body. This subject we must in future consider.

The fibrin is separated by inclosing the coagulum in a bag, by agitating and rubbing it between the hands in a vessel of water; thus separating all the soluble parts. It is obtained also by agitating the blood with the hands, or any instrument, when first drawn from the veins. In this way it adheres to either that is employed. Authors have supposed, that in the agitation of the circulation the fibrin is deposited, and forms the muscular fibres. This, however, is a refinement which will not bear examination. The juxta position of nutritive matter is carried on in the minutest elements; and, as in crystallization, we see only the effects of an infinite number of added molecules. Besides, we shall find reason to think that the embryo contains every organic part of the perfect man; and that the difference consists in the addition of matter not organised, interposed between the truly original organs. We have no instance of a muscle being reproduced. The ends are united by a firm ligamentous substance, and the motion of an injured part is thus preserved. But to return:

The coagulation is supposed to depend on the life of the blood, an opinion which we shall afterwards consider, or, in other words, on the irritability of the fibrin depending on *its* life. This idea of Mr. Hunter is, however, unnecessary; for the aroma of the blood may have, and very probably has, the power of hindering its coagulation in the body; a power, however, which is occasionally lost, since the albuminous and fibrous portions coagulate in many diseases. The basis of the crassamentum, which is the fibrin, appears to be a white solid elastic substance, more heavy than the serum. It is insoluble in water and alcohol; and contains a larger proportion of azote than any other portion of our fluids.

The colouring matter is that portion of the blood which, on the first employment of microscopes, excited the attention of observers. They found that it depended on red particles; but respecting their shape philosophers differed. Lewenhoeck described them as circular; and remarked, that, in passing into a vessel of a somewhat less diameter, they assumed an elliptical form; and that when brought to the orifice of an artery still smaller, they passed it, leaving the transparent fluids only to circulate through it. Haller does not greatly differ from this account. Mr. Hewson, probably misled by an optical illusion, considers them as flat, having a vesicle in the middle, containing a solid central particle. We have no reason to suppose this portion of the blood, from any office it can perform in the animal economy, would require a structure so complicated and almost organised. Dr. Wells, however, in the Philosophical Transactions for 1797, from a difficulty of explaining some of the chemical affinities of the red part of the blood, is inclined to adopt Mr. Hewson's idea; and the microscopical observations of father Torre seem to support it, though other observers confirm Lewenhoeck's description.

Mr. Cavallo, repeating father Torre's observations with similar lenses, saw the same appearances; but, following in his reasoning the laws of optics, drew a different conclusion. On the whole, he finds them spherical, or nearly so, consisting of double spheres; the light thrown on the internal having seemingly misled Mr. Hewson. Water, he found, dissolved them, though it loses this property if impregnated with common salt or nitre, or by the addition of a small proportion of vitriolic acid. Diluted marine acid did not dissolve them, but deprived them of their colour. Vinegar was a solvent, though inferior to water; and serum or urine would dissolve them after some days. When once dried or dissolved, they never recovered their shape; and when much blood had been lost, these globules were not soon again supplied. The red colour of the blood was long supposed to depend on iron; and M. Parmentier, with his associate, having found that iron, oxygenated by any means to a certain point, was capable of being dissolved by a fixed alkali, and imparting a red colour to a fluid, concluded with great reason that the redness of the blood was owing to this metal. Two scruples of iron were found in a pound of blood; and, if twenty-five pounds of this fluid be allowed to a man of a middle age and size, the whole amount of the iron will amount to nearly three ounces. The quantity of red blood is probably underrated; and, at least, one half must be added, so as to make the quantity of iron more than four ounces. Dr. Wells' objec-

tions to the colour being derived from iron, in the volume just mentioned, are strong and almost convincing; yet the arguments taken from chemical phenomena, in fluids less complicated than those of the blood, cannot be allowed to have the same weight as they would have in simpler fluids. They are too long either for an abstract, or for our consideration in this place; but when we reflect that the red colour is confined to portions found on inspection to be distinct, that we cannot examine these except when in a great measure broken down and mixed with fluids of very different qualities, we should be very cautious of deciding on their nature, from the result of experiments on solutions so essentially different. The red globules, for instance, are said not to be oily because they unite with water; but are we certain that the soda they contain may not occasion their solubility? or, on the other hand, who can say that we have yet ascertained all the aërial contents of this fluid, or the effects of those which it does contain? We mean not to urge either idea; but these suggestions are sufficient to apologise for our present scepticism, and for our considering the problem as yet requiring further investigation. We omitted to observe, that Abilgaard (Annales de Chimie, N<sup>o</sup> 106) found a larger proportion of carbone in the venous than in the arterial blood, and that the carbone of the arterial was lighter than that of the venous.

As the immediate causes of the coagulation of the blood were so obscure, Mr. John Hunter supposed it to possess life, and styled it, with Harvey, the '*primum vivens et ultimum moriens*.' Since his era, the discovery of the irritability of the fibrin has been adduced as additional evidence of this opinion. We know, however, that this fluid is continually changing, and that by nutriment primarily derived from the vegetable kingdom, it is regularly renewed. We may then ask, whether these fluids possess originally the living principle? Do the carbone and hydrogen which form the nutritious vegetable productions possess life? Do they assume this distinction only in the grass, or when they form a part of the system of the sheep or ox? In short, if they do not possess life originally, there is no period in which they can obtain this distinction, consistent with our present knowledge, unless we adopt the system of the Buffonian molecules organiques. Should this opinion be again assumed, we shall find it difficult to escape from the idea of life as connected with organisation; and of an organised fluid we have no example. One of Mr. Hunter's arguments is drawn from the white and the yolk of the egg, which, by possessing a principle of life, do not putrify during incubation. No profound knowledge is, however, required at this time to show, that in this instance there is a living organised body, and that the yolk is a part of the future chick; at least surrounded with its vessels, and drawn into its abdomen as its first nourishment. Another argument is, the production of vessels in coagulated extravasated blood. But, if the idea was correct, we should find no end to protuberances of this kind, and an ecchymosis must, in time, equal or exceed the bulk of the man; for as the blood is continually adding to the mass, and fresh vessels produced without limitation, this new living excrescence may equal that from which it was primarily drawn. Indeed the determined form of every part, the limits set to extraordinary devia-

tions in bulk or shape, show that some fixed principle regulates our form; and the various facts concur in proving the opinion lately hinted, which will be afterwards more fully explained, that the additions in the progressive stages, from infancy to age, are of inorganised matter only, and that the primordial stamina are unaltered in bulk or length.

Some other arguments adduced by this celebrated physiologist are, that persons killed by lightning, who have died in consequence of violent fatigue or by blows on the stomach; in short, in every instance where the irritability of the vessels is destroyed, the blood no longer coagulates. This, however, proves only that some circumstances will destroy the irritability of both; and we know an agent which will effect this completely, viz. hydrogen gas. We have employed the term irritability indiscriminately, because it will not be now contended that it is the exclusive property of *animal* life. Another argument is, that vegetable bitters, mixed with blood, did not hinder the coagulation, but that a solution of opium prevented it. This argument is peculiarly weak; for, if we can distinguish any appropriate power in the vegetable bitter, it is that of destroying irritability. The effect of opium in preventing the coagulation of the blood has been repeatedly denied; and some experiments adduced by an anonymous author, whose accuracy and judgment are so generally conspicuous as to demand our concurrence, have shown, that infusions, not only of opium, but of tobacco and *bella donna*, have not prevented the coagulation. In short, though this system is, on the whole, plausible, it will not admit of a fair examination; and, indeed, the reasoning of Mr. Hunter on almost every point of physiology is so vague and inconclusive, as to leave some doubt whether he has not in this walk more than counterbalanced the advantages which medical science has derived from his dissections and experiments.

Such are the properties of the blood in its natural state. In diseases it admits of little change, though the humoral pathologists copiously declaim on its viscosity and tenuity, its alkaline or acid acrimony. Blood drawn in inflammatory diseases, is at first streaked with purplish lines, and soon a yellow viscid coat covers the red globules; the sides of which often rise around, giving the coagulum the form of a cup. This coat, styled from its colour the *buff*, is so very dense as to justify, in some measure, the idea of the disease arising from lensor. Mr. Hewson, by an obvious, though a new, remark, taught us, that blood, in these circumstances, was not *more* but *less* viscid than usual; and that this crust was owing to the slow coagulation of the blood, by which means the red particles subsided, and left the albumen and fibrin colourless. In confirmation of this opinion, if we find the upper strata of the clot more, the lower are less dense than in the natural state. It is singular that this idea had not more early occurred, and we might then have found the tenuity of the circulating mass accused, for in the blood it was supposed the causes of disease *must be*. We think it admits of little doubt that the extraordinary agitation, and of course the more intimate mixture, of its component parts, occasion its slow coagulation, and the buffy coat. It does not, however, follow, that this is the only cause of the same appearance. Whatever occasions an increased

tenuity of the blood may have a similar effect. We thus find it in scorbutic cases, and in some species of typhus, as Dr. Lind, and MM. Parmentier and Deyeux have shown. In these instances the tenuity of the blood is not occasioned by agitation, but, in the first, by a probable increase of the proportion of neutral salts, with a deficiency of oxygen; and, in the latter, by a diminution of the proportion of fibrin or albumen: a change, however it may be explained, which is the constant consequence of debility.

A putrid state of the blood is frequently spoken of by pathologists, and may be very reasonably expected in the most putrid fevers. MM. Parmentier and Deyeux examined repeatedly that drawn from patients in fevers of the worst form. It did not yield volatile alkali by distillation, nor did it become putrid sooner than blood from the most healthy person. Yet, in various diseases, the albumen seemed affected; its union with the serum was less complete, and its concretion less perfect than in health. By analysis, the buff when present was similar to that from inflammatory diseases, and the coagulum below was tender: it was soluble in water; the solution was coagulated by heat, alcohol, and concentrated acids, while fixed and volatile alkalis rendered the colour more vivid, and prevented the coagulation.

In hectic the red globules have a more brilliant red, and the blood is generally buffy. The latter can be accounted for from increased action, and the former has been lately explained from the more rapid respiration, and consequently from the blood being more frequently exposed to the oxygen of the atmosphere. It is not, however, considered, that, in the greater number of hectic, the extent of the surface of the lungs is destroyed, in a greater proportion than is compensated by the repetition of breathing. When we contrast this appearance with the pale colour of chlorotic blood, we think it will be admitted that the cause lies deeper, and has not yet been discovered. If a deficiency or redundancy of the iron be allowed to occasion the diminished or increased colour, we must still examine from whence either proceeds.

It was once proposed to relieve diseases of the blood by a bold but singular experiment, viz. the transfusion of the blood of a young healthy animal into the veins of an aged or diseased person, while *his* blood was at the same time discharged from a distant orifice. The experiment was simple, and consisted of inserting each leg of a syphon into the aperture of an artery of the animal, and the vein of the patient. In the ardour which usually attends a new invention, it was supposed capable of prolonging life to an indefinite period; of correcting not only diseased states of the fluids, but even of correcting the disposition and temper. By a singular fatality, this project having been often employed, it is said with advantage, certainly without injury, was at once abandoned, in consequence of the death of a person, in which the operation could not be blamed. We can now see how little was to be expected from it, unless we could substitute the life of a calf or a lamb for that of the human body: but, the most zealous follower of Mr. Hunter would not willingly abridge *his* life to their period by transfusion. Numerous instances of the effects of this practice occur in the early volumes of the Philosophical Trans-

actions; and the outlines are given with great precision in their abridgment, by Dr. Shaw and his associates.

Another method of relieving diseases supposed to reside in the blood, was by injection of medicinal substances into the vessels; thus the medicine, taking the shorter way, was supposed to be more speedy and certain in its effects. But, the mildest fluids injected into the circulating system, were soon found to produce very disagreeable symptoms, and the plan is now wholly abandoned.

A singular mode of prolonging life was suggested by Lord Bacon, on the supposition that the heat of the blood exhausted the strength. He proposed cooling it by nitre; and thought that life might be in this way indefinitely prolonged. The experiment was never, we believe, tried: had it been so, little spirit of prophecy is required to foretell the event.

See, on this subject, Haller's *Elementa Physiologiæ*, vol. ii.; Plenck's *Hydrology*; Hewson's *Enquiries into the Properties of the Blood*, (*Philosophical Transactions*, vol. lx.) afterwards published separately; Fourcroy's *Système des Connoissances Chimiques*; Wells' *Observations and Experiments on the Colour of the Blood*, *Philosophical Transactions* for 1797; *Mémoire de MM. Parmentier and Deyeux*, *Journal de Physique*, vol. xlv.; Cavallo on the Medical Properties of Factitious Airs, 1798.

BLOOD, *discharges of*. See HÆMORRHAGES.

BLOOD, *medicines to check the discharges of*. See STYPTICS.

BLOOD, *dragon's*. See SANGUIS DRACONIS.

BLOW. The meaning of the term in general is sufficiently understood. The *blind* blow means that attended with no wound or ecchymosis.

BLUSHING, a suffusion of the cheeks, from a sense of shame or sudden surprise. It is supposed by Dr. Whytt to arise from the increased action of the smaller arteries; and, by Dr. Derham, from the near connexion of the fifth pair of nerves distributed on the cheeks with the brain. In fact, however, though the suffusion is chiefly observable on the cheeks, the glow is felt over the whole body. To the distribution of the fifth pair of nerves on the lips, Dr. Willis attributes the pleasure of kissing.

BO'A, a SERPENT, the etymology of whose appellation is unknown, which is met with in Calabria. Also a symptomatic kind of miliary fever, in which the eruptions are of the size of millet seeds, watery, without redness or pain, called *sudamina*, caused by inordinate sweating; called also *hydroa*. See PLYETIS.

BOA'NTHEMON, (from *βους*, an ox, and *ανθεμον*, a flower, so called from its likeness to the ox's eye). See BUPHTHALMUM.

BOBE'RRI. See BORRIBORRI.

BOCHE'TUM. A secondary decoction of lignum-vitæ, and of similar woods.

BO'CIA. See CUCURBITA.

BO'CIUM. See BRONCHOCELE.

BOD. à STAPEL. An abbreviation of *Johannes Bodæus à Stapel*, in Theophrasti *Historia Plantarum*.

BOERHAAVIAN SYSTEM. In a work of this kind, it would have been desirable to have given a

short account of the lives, and an abstract of the opinions, of the most eminent physicians. It was for a long time a favourite object of the editors to have thus interwoven the history of the progress of medicine; but the extent to which it might proceed, forbade the attempt. While, however, a short history of MEDICINE and its different branches will be found under that title, many reasons induced them to offer, in separate articles, a short account of the most distinguished systems. They need not conceal that the strongest of these was, that the early occurrence in the alphabet of the more important ones would enable them to give more fully the opinions on which the practical remarks in this work are founded. With these views, we shall in their place mention the BOERHAAVIAN, the BRUNONIAN, the CULLENIAN, and the STAHLIAN, systems, enlarging chiefly on the second and third, as they now principally influence the practice of medicine.

Few physicians enjoyed, for so long a period, such unbounded, such unalloyed, reputation as Boerhaave. He was represented, for we are old enough to have conversed with his favourite pupils, as equally amiable in private life, and respectable in science: he first gave chemistry a philosophical systematic form, and reduced medicine to a science at least plausible, neat, and perspicuous. At his era, the chemical reveries of Van Helmont were yielding to the more abstract sciences; and, from unreal fancies, the change to the necessity of demonstration was so rapid, as to leave scarcely the vestige of an intermediate step. Calm, penetrating, and reflecting, Boerhaave could distinguish between the visionary theorist and the attentive observer; and, equally judicious, could appreciate the merits of each. We have no reason to think that he expected to be the founder of a sect; yet he proceeded with the caution of a veteran, and culled from each the flower which was to adorn his own parterre. Though Paracelsus had burnt the writings of Hippocrates and Galen in solemn state, yet they were not forgotten; and the wise observations of the Grecian sages formed the ground work of his system. The Galenic doctrine of humours he assimilated with wonderful address to his chemical doctrines, and gave them a specific character, founded on their chemical relations. The mechanical philosophy, then attracting universal attention, added to the fabric: the vessels were cones or cylinders; the fluids, consisting of various particles, adapted only to given apertures, were at times forcibly impelled and impacted in vessels to which they were not fitted, and consequently produced numerous complaints.

The whole of this doctrine was combined with so much precision, with such scientific skill, as highly to prepossess even the experienced observer. Each found his own opinions placed in a respectable view, illustrated by language elegant and perspicuous, and supported by collateral doctrines, which, in another situation, he would have rejected. The Galenist could not object to the elegant illustration of the various humours; the chemist saw, with surprise, that the works which his master had burnt, illustrated his favourite system; and the mechanical philosopher, probably, never suspected the very extensive application of doctrines which he had cherished exclusively for their own

sake. In fact, Boerhaave's system was a selected one; and he has, of course, been styled an *Eclectic*.

We have engaged in this short comprehensive view, partly to account for the enthusiasm with which this system was received; for it must not be concealed, that, in treating of the properties and functions of a living body, he overlooked the principle of life, and the laws of a living organised machine. He seems to have seen his error, and in his later works he speaks, but still in the language of a sectary, of the 'inertia liquidi nervosi.' The first decisive step in opposition to this mechanical pathology was taken by his own nephew; and this heresy is followed, apparently, with some reluctance, by Gaubius, the pupil of Boerhaave.

Yet though we have spoken thus freely of his doctrines, we mean neither to depreciate the man nor his talents. He was far above the common race of mortals; and, with Newton almost alone, might be shown by angels as imitating their superior powers, and emulating their brighter intellectual acquisitions. When in different parts of this work also we speak disrespectfully of saponaceous aperients, of attenuants, and the other scions of the humoral pathology; or of the more rigorous demonstration of qualities and powers which refuse the trammels of mathematics, we must still profess an admiration of the talents of Boerhaave. Those who have contemplated the state of medicine, previous to his time, will see order rise from confusion, precision from vague analogy; in a word, science from doubtful unconnected facts.

The practitioners of the Boerhaavian school have, in general, been distinguished for patient attention and acute observation. They have not perhaps extended the bounds of medicine, but been contented to imitate their master, and his preceptors, Hippocrates and his successors. This was perhaps an error, and it resulted from the unbounded admiration they felt for Boerhaave. It was a very advantageous trait of Dr. Cullen's character, that he wished to raise his pupils into critics on himself. The writer of this article can add, that he received the most cordial assistance from the latter in a work, the leading principle of which was in opposition to one of Dr. Cullen's favourite doctrines.

BOETHE'MA, (from *βοηθω*, to assist). See REMEDIUM.

BOETHEMA'TICA SEMEI'A, (from the same, and *σημειον*, signum). Auxiliary signs in diseases, such as give notice of a cure observable in them.

BO'GIA GUM. See ESULA INDICA.

BOICIN'NGUA, BOICININ'NGUA. The RATTLE SNAKE, and *Dominicum serpentum*. *Crotalus horridus* Lin. It is said, that this serpent cannot approach a piece of a root which in Virginia is known by the name of *SENECA*, RATTLE SNAKE ROOT; but the blood root is the most frequent remedy against their bite, which, when bruised, is applied to the wound, and a decoction of it is drunk.

Troches are made with the gall of rattle snakes, which are caught in spring mixed with chalk or meal; these are called *trochisci Connecticutiani*, from the Connecticut colony. They are anodyne; three or four grains are taken after great fatigue, but may be given to fourteen grains or more.

When a person is bit by a rattle snake, purple spots, and a difficulty of breathing, soon attend. Many me-

dicines are used by the Americans as an antidote to the poison of this animal; (see *SENEGA*). Those in most esteem have a quick, warm, pungent taste, though mild and volatile on the tongue; but the most noted remedy is the following, which was discovered by a negro. Take of the roots of plantain and horehound, in summer the whole herb, a sufficient quantity; bruise them and squeeze out the juice, and give immediately a large spoonful. If the patient be swelled, pour it down his throat. If it does not relieve in one hour give a second spoonful, which never fails. If the roots are dried, moisten them with a little water. Modern practice has substituted volatile alkali and eau de luce.

It is said that rattle snakes have a power of charming birds, and other small animals, so as to make them their easy prey. This has been denied, and the appearances with greater probability referred to a restless anxiety for the safety of their young.

BOIL. See FURUNCULUS.

BOITI'APO. A serpent of Brasil, which the Portuguese call *cobus de cipo*. Its bite is venomous.

BOJO'BI. A serpent in Brasil, which the Portuguese call *cobre verde*. Its bite is venomous. The cure is the root of the *caa-apia*, which the patient is to swallow in a little water.

BOLBI'DION. A small fish, mentioned by Hippocrates.

BO'LBITON. BOLYNTHON. Cow's DUNG.

BO'LBCHON. See BDELLIUM.

BOLE'SIS. See CORALLIUM.

BOLE'SON. See BALSAMUM.

BOLE'TUS, (from *βαλος*, a mass). SPUNK. A genus of the fungi. It is an horizontal fungus; and porous underneath. The *BOLETUS IGNIARIUS* is commonly called *AGARIC* of the *OAK*.

BOLE'TUS CERVII. See AMANITA.

BOLE'TUS P'NI LA'RICIS. See *AGARICUS*.

Since the article on *agaricus* was printed, we have received a very laboured and interesting analysis of the white *agaric*, and *agaric* of the *oak*, from M. Bouillon La Grange, in the 151st number of the *Annales de Chimie*, of which we shall here give a short abstract.

He found the *white agaric* to contain an uncombined acid. Water dissolved a small quantity of extractive matter, as well as sulphates of potash and of lime, some muriat of potash, and an animal matter. When distilled in close vessels, acetat and carbonat of ammonia were formed. When burnt, he discovered, in the cinders, carbonats of potash and of lime, muriat of potash, sulphat of lime, phosphat of lime, and some iron.

With the assistance of nitric acid, the malic and oxalic acids were formed with a spermaceti, mixed with resin; alcohol extracted a large proportion of *acid resin*, which was the benzoic acid. Caustic alkalis separated a considerable quantity of ammonia.

From the *agaric* of the *oak* water took up an extractive matter, with sulphat of lime, and muriat of potash. In the cinders, when burnt, were found phosphats of lime and magnesia, with some iron.

With the nitric acid, the malic and oxalic acids were alone discovered. Alcohol dissolved only a small proportion of resin, and caustic alkalis disengaged a much less proportion of animal matter than from the *white agaric*.

BOLI'SMUS. See BOULIMOS.

**BOLSTER.** A soft pillow, to be laid under a broken limb, or a gouty joint.

**BOLUS,** (from βολος, *a mass*, from the Hebrew term *balah*, *to agglutinate*). A **BOLE** or **BOLUS**. Boluses differ not from electuaries, only they are made of a firmer consistence, in single doses, and therefore more proper where accuracy is required in the administration, and where evaporation would injure the medicine. The light and ponderous powders may more conveniently be mixed with mucilage, for so they are the least bulky. The quantity of each is as much as can be conveniently swallowed at once. The more disagreeable powders should be given in another form, and the more bulky doses mixed in draughts. This form is, however, now little employed, and the powders are usually mixed in draughts. Where swallowing is difficult, boluses are often improper. Yet we once saw ʒss. of valerian ordered in a bolus for a man in an apoplexy, by a fashionable physician.

**BOLUS, BOLE.** Boles are argillaceous earths, which readily fall down into a loose mass in water; smooth, and rather unctuous to the touch. It is the argilla bolus of mineralogists; and, like other reputed argillaceous earths, contains the largest proportion of flint. Boles were once highly prized; and the Armenian and Lemnian boles were dug and sealed with numerous ceremonies. They were accounted cordial, alexipharmic, and sudorific; and, in imitation of these, other argillaceous and calcareous earths were sold under the title of *terre sigillatæ*, because they had, like the two former boles, the impression of a seal. They are all now neglected; yet, were we to interpose against authority, we would whisper some defence of the former, *pulvis è bolo cum opio*, now the *pulv. è creta compositus cum opio*.

**BOLUS GA'LLICUS, FRENCH BOLE,** is a friable earthy substance of the argillaceous kind, intimately blended with a slight portion of ferrugineous calx, and siliceous earth. It is of a pale red colour, variegated with irregular specks, and veins of a whitish yellow. It is said to imbibe sharp acrid humours, and has been recommended in alvine fluxes and cardialgia, in doses of from ten to sixty grains. Pipe clay, coloured with red chalk, is its very innocent substitute. Its sudorific and alexipharmic powers have no foundation.

There are various other species that are not allowed to possess any medical virtues. The London college have consequently exchanged two compositions under the titles of *pulvis è bolo compositus, sine opio et cum opio*, for the *pulvis è creta compositus*, without and with opium. In the former, half a pound of prepared chalk is added to four ounces of cinnamon, three ounces of tormentil root, and as much gum arabic. In the latter, eight ounces of this powder are mixed with a drachm and half of powdered opium. Thus, about two scruples of the powder contain a grain of opium.

**BOLY'NTHON.** See **BOLBITON**.

**BO'MBATS,** (from *bombyx*). Salt formed by the union of the bombic acid with different bases.

**BO'MBAX.** **COTTON.** Called also *xylon*, *gossipium*, *cotonium*, *moulelavou*. *Bombax pentandrum* Lin. Sp. Pl. 959. There are three sorts of cotton trees: one creeps on the earth like a vine, the second is thick like a bushy dwarf tree, the third is tall as an oak. All the three, after producing beautiful flowers, are loaded

with a fruit as large as a walnut, whose outward coat is black. When this fruit is ripe, it opens and discovers the cotton; the seeds are separated by a mill from the cotton. This tree grows in many places in the Levant, East and West Indies, especially in the Antilles. The fruit is oval. The cotton of the first sort, which creeps on the ground, is the best: that brought from the East Indies is supposed to be the *byssus* of the ancients. That produced near Smyrna is greater in quantity than any where else. They sow the seeds, which are like little beans, in June; gather the cotton in October; and the soil there produces three crops in a year.

The skin of the seed is mucilaginous, the kernel is sweet like an almond, and of virtues similar to the althea. If cotton is applied to wounds, it excites inflammation; and, when worn next the skin it checks perspiration. That called *MOULELAVOU* is also denominated *arbor lanigera spinosa*; *gossipium arboreum caule spinoso*, *bombax ceiba* Lin. Sp. Pl. 959. A tall cotton bearing tree, of the bark of whose root an emetic is prepared.

**BO'MBICUM A'CIDUM.** **BOMBIC ACID.** Acid of silk worms. Silk worms contain, in every state, an acid liquor, in a reservoir placed near the anus; but at the more advanced periods of their growth it is mixed with a gummy matter. It is obtained by expressing their juice in a cloth, and precipitating the mucilage by spirit of wine, or by infusing the chrysalides in that liquor. This acid is very penetrating, of a yellow amber colour; but its nature and combinations are yet not well known. It has never yet been employed in medicine.

**BO'MBUS,** (from βομβεω, *to sound like a drum*). A **RESOUNDING NOISE**, from flatulencies rolling in different cavities. If a sound of this sort, or a ringing, is perceived in the ears in acute diseases, it is a dangerous symptom. It also means a noise in the bowels from flatus.

**BO'MBYX,** (from βομβεω, *to resound*). So called from the noise it makes in spinning its web. The **SILK WORM**. They are of no medical use; but it is said that if their bags are burnt they yield a larger quantity of volatile salt than any other animal substance, and consequently may be superior to burnt sponge.

**BOMPO'URNICKEL.** See **COLIPHUM**.

**BON ARBO'R.** See **COFFEA**.

**BO'NA.** The **KIDNEY BEAN.** See **PHASEOLUS**.

**BO'NDUCH INDORUM.** (Indian.) Called also *bonduch cinerea*, *bonduch pianta Indiano*, *arbor spinosa Indica muricatis siliquis*, *lobus echinatus*, *acacia gloriosa marsus*. *Guilandina bonduc* Lin. Sp. Pl. Wildenow, 534. **MOLUCCA NUTS,** and **BEZOAR NUTS.**

The plant runs up to five or six feet in height; it is a native of both the Indies. The round beans only are of use, which are of an ash colour on the outside, and white within. They are warm, bitter, and carminative.

Ray mentions another species, which he calls *bonduch*, *Indorum siliqua minime spinosa*.

**BON. SEP.** An abbreviation of *Bonetus Sepulchretum*.

**BONE.** Its Latin term, *os*, is supposed to be derived from the Hebrew word *ozam*, *strength*. The bones of animals constitute their firm, solid support; and their varied articulations give the animal that flexibility, those minute and complicated motions, on which our numerous functions depend. There appears to be no bone in the human body that does not possess every move-

ment required, except such as would be inconsistent with its more general and useful purposes. The solidity of bones depends on an earthy deposition, in a manner to be afterwards described; a deposition which some have styled a secretion, though with little propriety, as a bony substance is sometimes deposited by all the exhalant arteries: we have even seen ossifications in the corpora cavernosa penis. The bones are said by minute anatomists to be 304 in number.

Bones consist of fibres crossing each other in different directions. In the middle of the long bones these fibres are closely united, so as to form an almost solid substance. At their extremities the fibres are more distant, forming a distinct reticulated texture. As the long bones are solid, so they are hollow, to give resistance in a greater proportion than weight: the extremities are enlarged in bulk, to afford a more advantageous attachment to the muscles; but their cavities are divided into cells, and in these there is no part free from this reticulated substance. In this way, we believe, the weight of a given length at the extremity or the middle is not very different.

The substance of bones is now known to be a calcareous phosphat, which is deposited by exhalant arteries; and this substance is constantly renovated, while an equal portion is carried off by absorption. The part absorbed is carried off by urine; and we find in the disease styled mollities ossium the urine containing a large portion of this calcareous neutral. Lime is found in a great variety of our aliment; but the acid is the production of the animal economy, or rather perhaps a modification of some common acid, (probably the muriatic,) by means yet unknown to us. This calcareous salt is deposited in fibres in the long bones, and these fibres placed longitudinally are in the middle of these closely compacted, but diverge and separate towards the joints, leaving a space connected by cross threads of bone to form the net work. We find by proper preparation, not only this fibrous but a laminated structure also; that is, the fibres are disposed even in the hardest bones in strata, connected by crossing threads of a bony matter. The flat bones have no cavities; but, when they rise in protuberances, the same reticulated structure is observed in their substance: so cautious, apparently, is nature to give every advantage to the muscular power, without adding inconveniently to the weight.

The form which bones ultimately assume, is in a great degree owing to the action of the muscles and of the arterial system. In the youngest fetus indeed the general shape is observable; but the extremities are larger, and the cavities of the long bones still retain the reticulated bony structure. When the action of the strong muscles of the extremities condense the bony substance, these last cancelli disappear as no longer useful; but the tendons which possess no contractile power, cannot have the same effect on the ends of the bones, though these are in some measure condensed; for, by increasing age, their bulk becomes less, and their density greater. In old age the contrary change takes place. The bones indeed retain their form, but the proportion of the calcareous phosphat is lessened, and their specific gravity greatly diminished.

The process of the formation of bone was for a long time overlooked or mistaken; and even so late as the

era of Duhamel, it was generally thought that bony layers were deposited from the periosteum, as the woody layers of trees are from their bark. Traces indeed of more philosophical and correct views appear in earlier authors, but they were disregarded; and it was singular that it should not have occurred to Duhamel and his followers, that, if their system were true, man must yearly increase in bulk like a tree. Another error long prevailed, that bone was only a hardened cartilage. Were this the case, we should find the one gradually changing to the other: they are united indeed by bony protuberances in appearance, shooting into the cartilage, but it is at once obvious where bone ends, and cartilage begins.

In the fœtus, at its earlier stages, we find the future bone a gelatinous substance, covered with a membrane, the future periosteum. It gradually becomes firmer and whiter; but even at birth the bony system is flexible, so as to admit of considerable motion in all its parts, to adapt itself to the passage in birth. For a time a considerable proportion of the extremities of the bones is cartilaginous, which has occasioned the idea just mentioned; but when the change is carefully observed, new blood vessels are perceived to penetrate the cartilage, and the osseous matter is deposited from them in the body of the latter, which enlarges till it extends to the bone. This additional portion is for a long time easily separable from the rest of the bone, as united only by a layer of cartilage, and called an *epiphysis*; and when the union is more complete, this additional portion is called an *apophysis*. The object of this mechanism is easily explained. Bones are formed from the osseous matter deposited in points, which are either added to longitudinally, or in rays, as from a centre. Where great strength is required, the former structure is observable; but a continuation of the longitudinal fibres would weaken the bone, and a different direction is necessary; besides, as from bony centres, a substance is more quickly produced, when the child begins to walk, his strength will thus increase with a rapidity proportioned to his increase of bulk. We know that bones are nourished by arteries, since in young animals they are reddened by an injection thrown into the general arterial system; and in more advanced age, are coloured by feeding an animal with madder. The experiment so often tried and quoted to support many different systems, was not understood till lately examined by Dr. Rutherford. He found it to arise from an affinity between the colouring matter and earth, forming what the painters call a lake. If to a solution of madder in distilled water with muriat of lime phosphat of soda is added, a double decomposition takes place: the muriated soda continues in solution, and the colouring part of the madder is precipitated in union with the phosphat of lime. It is thus attracted in the blood vessels by the calcareous phosphat, and deposited with it.

Bones, if they have arteries, must have accompanying veins, and they have also absorbents; for a diseased bony part is absorbed as well as other parts of the body: and the cavities of the round bones bear the same proportion to the whole bulk of the bone in the fœtus and the adult. The earth when out of the circulation has no longer any peculiar quality; and when dissolved by spirit of salt, the vessels and membranes remain unchanged, displaying the same laminated arrangement as the bony

parts. The earth of bone is however valued as a material for cupells in the nice assays of silver, and styled *virgin earth*; but its properties are owing to a portion of the phosphoric acid. The circulation in the bones is peculiar. The vessels run in the direction of the fibres in the long bones longitudinally, occasionally dipping perpendicularly; in the flat bones they are radiated, diminishing towards the centre. The bones are full of pores for the admission of vessels: in the middle they are large and few; at the extremities smaller and more numerous. In every long bone, there is about the middle a hole for the passage of an artery and vein: the artery passes slantingly through the bone, branches on the internal periosteum, and externally *again* through the bone. These branches freely anastomose, and thus form an uninterrupted circulation between the internal and external parts. In the flat bones, the vessels anastomose in the medullium or diploe.

In their external form bones greatly vary. Besides the epiphesis, they rise, we have said, in various protuberances, named processes, and they are sometimes depressed in cavities. These if deep, with large brims, are called *cotylæ*; if shallow, *glenæ* or *glenoid*. Anatomists have employed other appropriate terms. Thus, *pits* are small roundish cavities; *furrows*, long narrow canals; *niches*, small breaches; *sinuosities*, broad superficial depressions without brims; *sinuses*, large cavities within the bones, opening by a small aperture; *foramina*, holes that pierce through the bone. Bones are usually divided into, 1st. *spherical*, which are spongy, except a thin plate on the surface: 2dly, *cylindrical*, which are compact in their middle, and spongy at their extremities; 3dly, the *flat*, which are compact on both sides, but spongy in the middle; 4thly, the *irregular*, which when thick are like the round, and when thin like the flat bones. It will be sufficiently obvious that these terms are not mathematically accurate.

Bones, we have said, owe their solidity to phosphorated lime. They contain also gelatine, and the proportion of each differs in different animals, and at different periods. The bones of an adult contain the greatest proportion of earth; those of a fœtus, of gelatine. Fish bones, from Mr. Accum's experiments, contain one-sixth part more of phosphoric acid than the bones of quadrupeds. Carbonated alkalis decompose the phosphate of lime in bones. They contain also a small proportion of selenite, carbonate of lime, and, according to Proust, of mineral alkali. Mr. Hatchett's late experiments in the Philosophical Transactions, greatly illustrate the chemical analysis of bone, horn, zoophytes, &c. but as less applicable to human bones, they fall not within our immediate province. See HAIR and HORN.

Bones are covered with a strong, firm, fibrous substance, styled *periosteum*, which is acutely sensible when inflamed, as indeed all the denser membranes are. Its chief use is to defend the bone, and perhaps to prevent its irregular growth. Bones themselves when inflamed are also highly sensible.

The internal parts of bones and the minutest cells are filled with marrow; a fluid fat contained in membranes, forming, in the language of some authors, the internal periosteum. The marrow does not differ in its analysis from suet and fat, or perhaps it has not been minutely examined. The marrow of herbaceous animals hardens when cold; that of carnivorous remains

fluid; and in young animals a little blood is occasionally deposited. We suspect that the harder fats are distinguished by their containing a larger proportion of oxygen, and the softer by a greater proportion of hydrogen or carbon. Marrow is contained in follicles not communicating with each other: at the heads of the bones these follicles are supported by the cancelli, but in the middle they have no such support, though the marrow is still confined by follicles, which lessen its weight on the lower parts of the bone, where the cancelli again lend their assistance. The bone is apparently always full. It has been supposed that the larger arteries which penetrate the middle of the bone, are exclusively appropriated to the nutrition of the marrow. The facts however lately noticed of the mutual anastomoses of the internal and external vessels, oppose this opinion, which, we believe, is not supported by any well authenticated observation. The use of the marrow is not known: it is a part of the adipose system, and perhaps intended for occasional support, and to correct the acrimony produced by inanition. Animals that remain torpid during the winter repair to their retreats with considerable coverings of fat, and leave them in a most impoverished state. We suspect also that the fat may be a reservoir of oxygen; for when this principle is exhausted little fat remains. In the last stage of phthisis some fat is found in the adipose membrane, and in this disease the oxygen is not deficient: but in dropsy it is quite exhausted; and in this complaint the retention of the excrementitious urine would be soon injurious, were not its acrimony blunted by either an oleaginous or an oxygenated fluid.

The products of bones employed in medicine are the empyreumatic oil, styled Dippel's animal oil, highly rectified. When distilled they afford ammonia; and from these the spiritus cornu cervi is now exclusively prepared. Bones calcined in open vessels are styled cornu cervi calcinatum, now seldom employed. The oil remaining after distillation burnt with the earth produces lamp black; the finest kinds of which are furnished by the more compact bones, and the horns of animals, thence called ivory black. Bones rasped and macerated in hot water, or exposed to considerable heats in Papin's digester, furnish a nutritious soup; and in a more condensed state a valuable glue. Six pounds of dry bone shavings produced fifteen ounces of clear glue; and fifty pounds of ivory shavings yielded nine pounds and a half of transparent glue. The exact proportion of gelatine in bones has not however been ascertained, since the driest glue contains some water. These preparations were made by boiling only; but the soluble parts are more perfectly extracted in Papin's digester, though the fat acquires an unpleasant empyreumatic flavour. Proust informs us, that the enlarged extremities of the bones, boiled for a quarter of an hour in water, yield one-fourth of their weight in fat, and the haunch bones one-eighth. The hard bones must be powdered, reduced to a fine paste by trituration with water, and boiled for a longer time. See Proust's 'Memoir for Meliorating the Condition of a Soldier,' published at Madrid 1791; an abstract of which may be found in the 53d volume of the Journal de Physique.

The diseases of the bones, independent of FRACTURES and DISLOCATIONS, are WOUNDS, NECROSIS,

CARIES, EXOSTOSIS, OSTEO SARCOMA; including SPINA VENTOSA and PEDARTHROCAE, RICKETS, FRAGILITY of the bones; injury from RUPTURED LIGAMENTS, DROPSY in, and WOUNDS of, the JOINTS, WHITE SWELLING of the joints, ANCHYLOSIS, DISTORTION, MOLLITIES, SCROFULA.

See Haver's Osteography, Monro on the Bones, Cheselden's Osteology, Memoires de Pelletier, vol. ii. Proust (Journal de Physique, l. c.), Hatchet, Phil. Trans. 1799, 1800.

BONIFA' CIA, (from *bonum*, good, and *facio*, to do,) from its utility to the human frame. See LAURUS ALEXANDRIA and HIPPOGLOSSUM.

BONONIE'NSIS L'APIS. The BONONIAN STONE. Called also *phosphorus Bononiensis*, *spongia solis*, *lucidus lapis*, *illumina bilis lapis*, *phosphorus Kircheri*; the LIGHT CARRIER and BONONIAN PHOSPHORUS.

It is a small, grey, soft, glossy, fibrous, sulphureous stone, about the size of a walnut. When broken, a kind of crystal, or starry talc, is found in it. This stone is met with in the neighbourhood of Bologna, in Italy; and, when duly prepared, makes a species of phosphorus.

This phosphorus gradually emits light for six or eight hours after being exposed to it. As a medicine, the stone is caustic and emetic; and the phosphorus itself has been highly injurious, when used as a medicine.

BONT. An abbreviation for *Jacobius Bontius*, a writer of good credit.

BO'NUS HENRI'CUS. See MERCURIALIS.

BOO'NA. See PHASEOLUS.

BORA'SSUS. The tender medullary substance which grows at the top of the great palm tree.

BO'RAX, (from the Arabic term *borac*). Called also *chrysocolla*, *capistrum auri*, *ancinar*, *boraxtrion*, *anucar*, *atincar*, *tincal*, *amphitane*, *baurach*, *nitrum facitium*, *santerna*, and *nitrum nativum*. Borac signifies nitre, but it was corrupted into borax, and applied to the chrysocolla. It is not much unlike alum, and if genuine, hath a sweet taste at the first, but afterwards an unctuous one. Its pure crystals are hexaedral prisms, terminated by three sided summits finely cut; it dissolves with difficulty in cold, but easily in boiling water; requiring of the former more than twelve times its weight. It is soluble in alcohol, swells and bubbles in the fire, and soon becomes a glass, which dissolves again in water; but if mixed with flint or sand, it becomes a durable glass, hard enough to cut common glass. It is an excellent flux for metals, and for their ores; changes the colour of blue flowers to green; precipitates earthy and metallic bodies dissolved in acids; and renders vegetable and animal oils miscible with water. A solution of borax made in a menstruum of vegetable acid, when inspissated by evaporation, is a tenacious substance that will not crystallize, but will dissolve in the air. Borax was originally brought from Thibet, where it was found on the shores of a lake, seemingly the crater of an old volcano. We receive it inviscated in a greasy substance, and in an impure state, then called *tincal*. It has been since found more pure in the mines of Ritiniquipa and Escapa, and still more pure in China. In Europe it has been discovered in a mineral lake in Tuscany. It is purified by long boiling and repeated crystallization; but when most pure, white, and transparent, it has a somewhat greasy fracture. We now know it to be a compound salt, with an ex-

cess of alkali; containing thirty-nine parts of boric acid, seventeen of soda, and forty-four of water. It is decomposed by barytes, magnesia, and lime.

Its acid, the sedative salt, is of a white, scaly, glittering appearance, has a cooling saline taste, and reddens the blue vegetable infusions. A pint of boiling water dissolves 183 grains, but it dissolves more easily in alcohol. Its solution in spirit is green, and burns with a green flame. If dry, it is fixed in the fire.

The borax of the shops is sometimes adulterated with alum: but then it is not so light nor clear, nor does it swell so much when put on burning coal.

Borax itself is used for soldering gold, whence its name *chrysocolla*. It is also a solder for other metals; and a powerful flux for fusing minerals of all kinds. It is used to give a gloss to silks.

As a medicine it seems to possess inconsiderable virtues, or these have not been sufficiently examined. It has been, however, styled a deobstruent, diuretic, and emmenagogue, in doses of half a drachm, or two scruples. A mixture of it with honey—viz. borax one drachm, honey one ounce—is efficacious in removing aphthous crusts from the mouth and fauces, but a solution in water is considered to possess superior power. Externally it is a far better cosmetic than bismuth. If given in powder it is said to be emetic, but, mixed with aromatics, this quality is checked, and in the fluor albus it is supposed highly useful.

A dose of borax is from gr. v. to ʒiiss.

BORBONE'NSIS, or BORBO'NICA. A patronymic epithet for the Bourbon water. See AQUE SULPHUREE.

BORBORO'DES, (from *βορβορος*, filth). FECULENT, MUDDY, DIRTY, EARTHY.

BORBORY'GMUS, (from *βορβορυζω*, to make a noise). A rumbling noise, excited by wind in the bowels.

BO'REAS. The NORTH EAST WIND. The northern winds are cold, but, unless in the east, not unwholesome. They resist putrid diseases, but often occasion those that depend on an inflammatory state.

BO'RI. (Greek). GREAT EATERS.

BORI'DIA, (from *βορρ*, food). Salted fish eaten raw. Oribasius.

BORO'ZAIL. The ZAIL of the Ethiopians. It is a disease epidemic about the river Senegal, principally infecting the pudenda, but different from the lues venerea, though owing to immoderate venery. In the men it is called *asab*, in the women *ossa batus*.

BORRA'GO, vel BORAGO, formerly written CORAGO, the C being now changed into B, (from *cor*, the heart, because it was supposed to comfort the heart and spirits). BORRAGE. Also called *buglossum verum*, *buglossum latifolium*, *borago officinalis* Lin. Sp. Pl. 197. Nat. order *asperifoliae*; *boragineae* of Jussieu.

The leaves are succulent; their medical qualities are not discernible until the juice is separated by pressure, and are then inconsiderable. A decoction of them affords a small quantity of the nitrous and muriatic salts. The leaves are ranked among coolers, and the flowers among cordials. See also BUGLOSSUM.

A syrup is prepared from the leaves in France, and used in pleurisies and inflammatory fevers. It is sometimes put into negus, forming what is called a cold tankard.

BO'RRI-BO'RRI. BOBERRI. (Indian). See CUR-M m

CUMA. It is also a name in the East Indies of an ointment in which are the roots of turmeric.

BOS, (from *βωω*, to bellow). The BULL, COW, OX, HEIFER, or any other of the neat kind. See ALIMENT.

As a medicinal article, we may reckon BEEF TEA, which is thus made: Cut a pound of the leanest part of a buttock of beef into thin slices, add to it two pints of boiling water; keep the water just below the boiling state, and let it infuse for near an hour, having previously added about twenty or thirty pepper corns and a little mace. By infusing only, it retains the lightest parts of the nutritious lymph, which boiling dissipates, and seems more agreeable to stomachs greatly debilitated. It may be salted when drunk.

BO'SA. An Egyptian word for a mass which is made of the meal of darnel, hemp seed, and water. It is inebriating.

BOSCAS, (from *βοσκαω*, to feed). A sort of dry pitch, which is tenacious like bird lime. Also the mallard.

BOS INDIA'NA. See BUBALUS.

BO'TANUM. See PLUMBUM.

BO'TANY, (from the Greek word *βοτανη*, a plant). In its strict meaning it is the science of plants; but in such a very extensive view it cannot be treated of in this place. Botany is divided into the classification and nomenclature of plants; an account of their virtues in medicine; in dietetics, and the various arts; their physiology, and their diseases. Botany, though plants must have been from the earliest ages observed and employed, is not a science of high antiquity. In the ruder periods, a few culinary and medicinal plants were probably discovered; their forms were pointed out by fathers to their children, and their virtues were equally handed down by tradition. Knowledge of this kind is soon corrupted or lost. If a name be given, it is applied by another to a plant which resembles it, whose virtues may be different or contradictory; and if the family emigrates, the experience of ages is lost, should the same plant not be discovered in their new habitations. Our earliest records, the sacred writings, speak of few plants, though of several vegetable productions which are now ascertained with sufficient accuracy: but we cannot judge of the botanical science of Solomon, who is said to have been acquainted with all plants, from the cedar of Lebanon to the hyssop that groweth on the wall. The plants mentioned by Homer are not numerous, but an interesting and amusing work might be still written on those which occur in his poems. Hippocrates, our great object, speaks of the virtues of about two hundred and thirty plants, which were described by Cratævas his cotemporary: but the first great luminary in this science was Theophrastus, to whom we are indebted for some very accurate descriptions of plants; and he was followed by Dioscorides, who describes about four hundred and ten species, and mentions, by name, about one hundred and ninety others.

Even in that state botany became an unwieldy mass, from its bulk and want of arrangement. The descriptions of Theophrastus are vague and imperfect; though, as the scholar of Aristotle, we may expect to find in him all the science of the Stagirite, whose work on plants is evidently the forgery of a later age. His arrangement is taken from their size or their virtues, and little calculated to assist the tyro in the investigation. The de-

scriptions of Dioscorides and Pliny deserve not a higher character; and had it not been for the labours of the Bauhines, whom we shall afterwards mention, we should have attained but little knowledge from the accumulated acquisitions of fifteen centuries.

Gesner, who flourished about the middle of the 16th century, was the first author who saw the necessity of arrangement, and the advantages to be derived from dividing plants into classes, orders, genera, and species; but it was only after fifty years that Cæsalpinus began the attempt; and more than one hundred, before Morison and Ray produced the outline of a plan which approached perfection.

In this interval some works appeared which are more important, as more nearly connected with our subject. Dr. William Turner, the father of English botany, since he gave names to many English plants, published his Herbal, with the plates which belonged to the botanical work of Fuschius. The different parts appeared at different places, from the year 1551, the date of the first, to 1564, that of the last part. His arrangement is, however, an alphabetical one of the Latin names. About the same period, viz. from 1552 to 1583, Dodœus collected his works into one system, called *Stirpium Historiæ sex Pemptades*, the foundation of Gerard's, and every subsequent herbal in our language. In Gerard we perceive the first traces of a natural arrangement; for his first book contains the grasses, grain, rushes, reeds, flags, and bulbous rooted plants. This author's idea of the union arose, however, from the simplicity of the leaves. His second and third parts offer no very remarkable traces of arrangement. In the third, however, he has grouped the heaths, the mosses, mushrooms, and sea plants. These herbals are more to our purpose, as they unite botanical descriptions with medical virtues; but the system adopted is that of Galen, and with a profusion of virtues which each plant is supposed to possess, we are constantly told in what degree it is hot or cold.

Before, however, we approach the luminous period of classification, we must notice a work, whose peculiar merit and utility, in a medical view, have been greatly overlooked; we mean the Pinax of Casper Bauhine. Of the elder Bauhine (John) we need say little, but his three folio volumes, containing a general history of plants, are a work of great labour and utility; though, from the want of arrangement, it is of much less advantage than we might expect. The Pinax of the younger Bauhine contains the names of six thousand plants, to be found in the writings of Hippocrates, Galen, and the other ancient physicians; of Theophrastus, Dioscorides, and the elder botanists. In this work some traces of arrangement appear, which the following quaint verses will explain:

*Gramen adest, bulbusque, olus atque umbella, venenum;  
Atque corona, odor et flos est vescumque legumen;  
Carduus in spinis, frutex succedit et arbor.*

In this order, though not formally pointed out by the author, the plants are arranged, and several of these families are truly natural. The species are collected under natural genera; and as trivial names were not then invented, each species is shortly described. The synonyms of the different preceding physicians and botanists follow; and to make the use of this Pinax more easy, every name with the reference occurs in a full index.

We have in this way, at one view, whatever has been said of every plant then known; and to make this connecting link between ancient and modern science more completely useful, Linnæus has added the description of Casper Bauhine to each of his species. Thus, then, when we refer to the Linnæan species, we unfold to the medical reader the plant of which Hippocrates and Galen spoke, the author where each has been fully described, with all its real and supposed virtues.

Morison, in a second edition of the *Hortus Regius Blesensis*, gave, in 1669, the rudiments of a method founded on the fruit; but the remembrance of this proposal has been obliterated by the splendour of Ray, who published his *Methodus Plantarum Nova*, in tables. He divided the vegetable kingdom into trees, shrubs, and herbaceous plants; classing with the latter the suffrutesces, the lesser shrubs. His great object was to connect the natural families, or the plants united by a similarity of fructification and general habit; but his genera were more loosely and imperfectly grouped; and in this first imperfect attempt we wanted both descriptions and synonyms. His system appeared in a more accurate and complete state in his *Synopsis of British Plants*, and his *History of Plants*. Two editions of the *Synopsis* were, we believe, published during his life. The most complete is the third, published in two vols. 8vo, 1724, near twenty years after his death.

It belongs to the general history of botany to pursue the various modes of classification proposed and adopted by different authors. It is our object in this sketch, chiefly to point out the progress of *Medical Botany*, and of the arrangement of plants in natural families, the means as we think of improving it. Though we greatly admire the ingenuity of the system of Tournefort, and, with all their imperfections, find considerable merit in those of Sauvages and Haller, we must chiefly confine ourselves to Linnæus. From the year 1735 to 1737, the different publications which announced his system appeared; and it was gradually improved to the last period of his life. It is styled the *sexual* system, because he supposed plants distinguished by sexes, the antheræ being in his opinion the male, and the pistils the female organs. From the number, situation, and connection of the former, his classes are chiefly denominated and distinguished; from the number of the pistils in general, the orders. It is confessedly an artificial system, but many of the families of plants are preserved undisturbed. Whatever are its imperfections must be now overlooked, since in the present vast extent of botanical science, this system only is commensurate with it. Various attempts have been made to correct and improve it. Thunberg attempted to render it more simple by diminishing the number of classes; and Gmelin has added to them. Botanists, however, have received each offered improvement with caution; and, as Dr. Smith has almost scrupulously adhered to the arrangement of the Swede, and Wildenow in his new edition of the species followed it without alteration, there is little probability of its being now disturbed.

A natural method, however, appeared always from the confession of Linnæus himself, the first and last object of the botanist; and in his *Philosophia Botanica*, a work published in 1751, often highly praised, but

scarcely ever in proportion to its merits, he introduces what he styles 'Fragmenta Methodi Naturalis,' viz. fifty-seven natural orders or families of plants. We mean not to say that this was the first example of a natural method. Morison's and Ray's were certainly such; and previous to these, in 1626, Laurenberg published at Rostock his *Botanotheca*, in which he distinguished ten natural families of plants with tolerable accuracy. Ray's four classes, taken from the cotyledons, branched out into twenty-nine families, the greater number of which were natural groups. The cryptogamiæ and capillary plants we of course exclude. Besides our countryman, Royen of Leyden, in 1740, gave an elegant natural arrangement; Haller, a more laboured and a less useful one; and Wachendorff of Utrecht, a system not inelegant, but deformed by titles peculiarly complicated and compounded. At a later period, viz. in 1766, Crantz of Vienna published his *Institutiones Rei Herbariæ*; in which, by an arrangement neither neat nor convenient, he has, however, retained many of the more natural groups or families of plants. About the same time, Adanson formed his natural classes; but these are so *strictly* natural, that his definitions become descriptions, tedious and useless from their extent, since he includes a similarity in every part. Gærtner, in his arrangement from the seeds, without pretensions to natural orders, has formed numerous natural groups which well merit the attention of the botanist. The most successful modern attempts are those of Jussieu and Murray; the former more strictly botanical, the other subservient to his excellent work on the *Materia Medica* (*Apparatus Medicaminum*). Anthony de Jussieu is the nephew of Bernard, demonstrator in the royal gardens at Paris, to whom the merit of the first attempt is due. It was from Bernard Jussieu that we received the first systematic work of this kind in 1789, viz. *Genera Plantarum secundum Ordines Naturales disposita*; and from him Adanson, who was his pupil, probably derived his ideas. This was the foundation of the last and best natural botanical system that has appeared, viz. *Tableau du Regne Vegetale selon la Methode de Jussieu*, par E. P. Ventenat. The system of Murray we shall soon notice.

We have enlarged on this part of the science of botany, because we perceive a very intimate connection between the natural orders and the medical properties of plants; and because this part of the subject has not yet received the attention which it so justly merits in this point of view. The Linnæan system we have said is artificial; but it is not to be rejected on this account. With its aid we can at any time distinguish a plant, convey an accurate idea of its general form, and arrange it so as that future observations may be directed to their proper object; in short, for the purpose of discrimination, and the reference of synonyms, it is highly valuable. As an artificial method also it is always complete, so far as our knowledge extends. There are no lacunæ to be filled up, there are no links to be supplied. A natural method cannot possess such advantages. In reality, the further our knowledge extends, the more imperfect it becomes, for 'nature makes no leaps;' and the lacunæ, which, in the present state of science, give limits to the orders, will, when supplied, no longer enable us to discriminate them. In a general view, therefore, the clas-

sification and nomenclature of plants may be advantageously supplied by the Linnæan system; the union of properties and virtues by the natural families.

The opinion that the genera of the same natural orders possessed similar medical powers, is by no means new. It was suggested in the Philosophical Transactions by Mr. Petiver, and is enforced by Hoffman in a separate dissertation. In 1784, a slight lively work appeared on this subject, entitled 'A Short Attempt to Recommend the Study of Botanical Analogy.' The author's aim seemed not to be deep investigation, but to catch the attention by a few prominent facts, for the purpose of a more complete examination of the natural orders by himself or others. No publication has, however, appeared in the same path, nor will the limits of the present article enable us to give more than an outline: we hope, however, to make it tolerably complete.

Several of the fragments of the natural orders left us by Linnæus, contain no medical plant. They were published by the author without a comment; and we now find that he gave only at two very distant periods, lectures on this subject, viz. in 1764, to Ferber the future mineralogist, Fabricius the entomologist, to Zæga, to Kuhn of Philadelphia, and the chemist Meyer; and in 1771, to Giseke, Vahl, the celebrated botanist, to Edinger, and Tislef. From Giseke we have received an account of these lectures, published at Hamburgh in 1792; a communication truly valuable, as he compared the manuscript of Fabricius with his own, and marks the agreement and differences.

The idea of natural orders includes the want of connection into classes and systems. Linnæus, we shall find, had undoubtedly some views of connecting these fragments, but he often declared that he would not relate, on this subject, all that he knew. He was irritated at the injurious treatment different parts of his labours had received, and particularly the Fragments, so that he was with reluctance led to lecture on the subject. The formation of natural orders is a task of considerable labour, and we cannot better explain the difficulty than by translating the conversation between Giseke and Linnæus: it is in many respects curious.

"Before, however, he began them (the lectures), we often disputed on the subject. I had thought that all the species of columniferæ, for instance, should have a stamiferous column, and that those without it should be excluded from the order; while those distinguished by it, agreeing in other respects, thus formed the natural group. I thought the same of the bicornes, tricocceæ, and others. Linnæus smiled, and told me, that we must not always determine from the name; that there were plants so nearly allied to the columniferæ, though without that distinction, which could not be separated. He went on, and convinced me that there might be sometimes a single mark, which was found in all the plants of that order, which even gave it the name, but did not sufficiently distinguish it from others. Thus the siliquosæ have each a silique, but no one in their senses will expect to find every siliquose plant in this order: the hypocœum, chelidonium, cleome, caparis, fumaria, and epimedium, are all siliquose; but how different! how irreconcilable! Hence, he added, those who, on account of the silique, unite them to the

cruciformes, or, in consequence of this distinction, unite other orders with it, do not understand my orders. I replied, what then is the use of a name, if the mark pointed out by the appellation does not suit every individual? It is of little consequence, he added, what the name is, so that it has some connection with the series of plants, and it is ascertained that you speak of a particular group which you have united. I have followed the axiom of the logicians, *à fortiori denominari*. Can you give me the character of one order? G. I think I can; of the umbellatæ, for instance.

"L. What is the character of the umbellatæ? G. That circumstance, viz. their flowers being disposed in an umbella. L. Right: but are there not plants whose flowers are umbellated that do not belong to it? G. I recollect; and must therefore add two naked seeds. L. Then the echinophora will not be of this order, which bears its seed in the centre of the peduncle, yet it is umbellated: and to what order would you refer the eryngium? G. To the aggregatæ. L. By no means: it is certainly umbellated; for it has an involucre, five stamina, and two pistils: what then is its character? G. Such plants should be placed at the end of the order, to connect it with other orders: perhaps the eryngium would unite the umbellatæ with the aggregatæ. L. It is a very different affair from giving the characters of orders to point out transitions. *I know the orders, and their connections, but these I will not explain: I will never explain.* If, however, the character is a mark to distinguish the object from every other; if the orders are to be discriminated; if the agreement of the orders forms a class; and the connection of classes a method; we cannot have a natural method in botany, for we must first complete the characters of the orders: but this is impossible. Take any order you please, and you will see it cannot be done.

"G. The contortæ have a very distinct character, viz. the contortion of the corolla, previous to its expansion. L. The malvaceæ, however, have the same peculiarity of the leaves, though wholly different.

"G. Perhaps, then, the tricocceæ? L. Ah! the cambogia has an apple. G. And the hura a multivalve capsule, the hippomane a fruit; so that they must be removed from the order. L. No, they cannot, and should not be removed: the connection is so intimate, and the other species of hippomanes, except the h. mancinella, are really tricocceæ. G. I wonder, therefore, that you did not insert the tropeolus. L. (smiling), I wish you understood affinities! In that case I should have opposed nature; and the rhamnus should be inserted also. G. Why not? L. The celastrus cannot be separated from the euonymus, which has five berries, nor this from the rhamnus. G. These things appear to me very obscure. L. I think so. There was, in 1771, one Fragæus at Petersburg, an assiduous man, who determined to find out a clavis for my orders, and, after labouring for nearly three years, sent me his 'scheme.' I laughed heartily, and replied, learn first what is a natural order, and I showed him. But this I know, if I publish another edition of the genera, I will make a new arrangement of the orders, and change them in many respects; for the former orders of the list are more nearly connected than the latter. I would also arrange the rest, so as to divide them into groups, equally natural with the first

and second. G. Excluding, however, the ferns, and those which follow. L. Entirely; for these would make another group.

1. . 11.  
 " Monocotyledones. Dicotyledones & Polycotyledones.  
 Ord. I—X inclusive. Ord. XII—LIV inclusive.

111.  
 Acotyledones.  
 Ord. LV—LVII.

Of the XIth order some have single, others double cotyledons; but the reason of the subdivision of the cotyledons I will not add. Perhaps you, or some one, at a distant period will discover it, and you will then see that I was already acquainted with it. But you must labour hard at it for ten years at least.

" G. But why, I pray you, will you not now give the reason? L. Because my orders were unfavourably received by those who did not understand them. Of the first class I had the connection in my mind; and in the second and third, I know that some are more nearly related than others. Where it was in my power I have given them their proper situation. Thus, the papilionaceæ are related to the lomentaceæ; the umbellatæ to the hederaceæ, but yet distinct. Others may have a less manifest connection: some have none. I should wish to know with what orders the siliquosæ are connected?"

If this extract appears to have little affinity with the great object of the work, it must be recollected that we shall endeavour to point out the connection between the natural affinities and the medical powers of plants, and that it is of course necessary to show in what these natural affinities consist. These doctrines will also assist in some other arrangements, which must be the subjects of our consideration. At all events, little has been said in any botanical work on the subject, and the explanation is wholly new to the English reader; consequently interesting. We may remark, that M. Giseke has prefixed what he styles 'A Geographico-genealogical Map of the Affinities of the Orders.' This consists of circles of different diameters, each of which has the title of one of the orders, and is of a size proportioned to the number of its genera. They are at different distances according to the affinity: some touch, others pass beyond the circumference of its neighbour when the affinity is considerable; and, at the point where they touch or encroach, we find the connecting neighbouring genera. Let us just mention a fact, that in the moment occurs to us on inspecting the map. The palmæ are nutritious, and in different parts farinaceous: the order most nearly connected with these is the tripelatoideæ; and the connecting genus is the *butomus*, which we have very lately learnt from the Russian naturalists is employed by the Kalmucks to make bread. The species is the *b. umbellatus*. Numerous observations of a similar kind we shall have occasion to add.

The first of the *Linneæan natural orders* is the PALMÆ. These are sufficiently distinct in their form and their properties. A farinaceous or an oily substance abounds in all the species; and so rich is the palm in supplying all the wants of man in a less artificial and refined state of society, that where these trees abound,

scarcely any thing else is wanting for food, for defence, or for convenience.

The second order, the PIPERITÆ, contain but few genera; but all are pungent or aromatic. The pepper, the arum, the calla, the acorus, and dracontium. Of these the acorus only is aromatic. The CALAMARIÆ are the rushes, of which the *carex arenaria*, and two species of *cyperus*, are employed; and agree in a warm strengthening quality, which adapts them for humoral asthmas, and for rheumatism. The *c. arenaria* is called the sarsaparilla of the Germans. It rather, however, resembles the guaiacum.

The GRAMINÆ, which include the various kinds of the cerealia, seem to contain in the greater number of species a saccharine and farinaceous matter evolved in different parts of the plant. The former is often found in the leaves, though more generally in the seeds, always to be elicited by a slight preparation. Instances of these properties may be found in the sugar cane, and in barley; from which, by heat and moisture, malt is formed. These are connected, by botanical analogy and medical properties, with the rushes on one hand, and the oleraceæ on the other. One species of *lolium* is the only plant of this order supposed to be injurious, and the only one of the order used in medicine: the *gramen caninum* was employed on an uncertain foundation, and is now neglected.

The TRIPETATOLOIDÆ, which follow, are related to the rushes and palms. The *butomus*, as we have observed, is a connecting link, but the species have no medical virtue. A species of the *calamus*, viz. *c. rotang*, is said to produce the *sanguis draconis*; but this is doubted, and the medicine itself scarcely possesses any powers.

The ENSATÆ contain only the crocus and the iris, employed in medicine; and, as the former is now found to be useless, we cannot compare the medical powers of the two genera. In the roots of the iris there is an astringency with a considerable acrimony, and they have been employed with success in dropsy. From general affinity, the *colchicum* should perhaps have been inserted in this order. Botanical refinement alone seems to have excluded it.

The ORCHIDÆ contain the orchis; several species of which are at different times employed to produce the nutritious farina, the salep. The only other genus employed is the *epidendrium*, which furnishes the vanilla. This also is nutritious, and, in the opinion of Linnæus, (*Amœnit. Academ. vol. vii.*) aphrodisiac.

The SCITAMINÆ are almost exclusively aromatic and mucilaginous, if we except only the *musa* and *canna*; which, as nutritious substances, are not very distant. This order contains the ginger, the cardamoms, the *costas*, *galangals*, and *zedoary*. The *acorus* is the only European plant, though not a medicinal one. The *musa* is not properly a species of this order.

The SPATHACÆ, the next order, are not very strictly medical, or probably natural. Its characteristic is a bulb, consisting of the bases of the leaves of the preceding year, and consequently tunicated; but a gem consists only of the rudiments of the future leaves. In the latter, the scales become leaves: in the former, the bases of the old leaves become fleshy. All the *spathacæ* are acrid, but this quality is vague; and we think Mur-

ray, among some useless or inconvenient alterations, has properly united the garlic, the colchicum, the crocus, hellebore, sabadillum, the squill, and several similar medicinal plants, under a new order, the *liliaceæ*. Many of these are included by Linnæus under the following order, the *coronariæ*; a term by no means descriptive, as it implies only a group of beautiful flowers, employed in making garlands, coronæ. The chief difference between these and the *spathaceæ* consists in the *spatha*. The roots of some of these plants are esculent, but it is not uncommon to find considerable acrimony sheathed in the root by *farina*.

The *eleventh* order, the *sarmentaceæ*, called from their having weak branches, in Latin *sarmenta*, is not strictly natural; and, in a medical view, contains plants of somewhat dissimilar powers. The *sarsaparilla*, the *china*, the *rusous*, the *serpentaria*, and other species of *aristolochia*, agree in being moderately warm and diaphoretic. One species of *alstromæria*, the *a. ligta*, has been employed for similar purposes; yet many are acrid and poisonous, of which our *materia medica* contains only the *asarum* and the *cocculus indicus*. The *asparagus* and *cissampelos* (*pareira brava*) are diuretic, not without suspicions, in a more advanced state, of deleterious powers. The *convallaria sigillum Solomonis*, Murray has with propriety referred to his *liliaceæ*. Its roots in Sweden are prepared like the *cassada*, and eaten as bread; the roots of the *calla* in the north of Europe, and the *arum colocasia* in Egypt, are employed in the same manner.

The *oleraceæ* contain the esculent herbs and roots; as the spinach, the beet, and similar plants. Linnæus, however, has added, with less strictness, some other medical groups, the docks, the laurels, and the *canella*. The first deviation is in the *hernaria*, which is slightly bitter; and from hence he is led to the docks, which are in their leaves herbaceous; and to the laurels, by steps still less obvious and natural. He is, however, in this indiscriminate arrangement, which he very lamely defends, followed by Murray.

The *succulentæ* are a strictly natural association. The house leek is an example. About six genera of this order are occasionally used in medicine, though of weak powers. They are all succulent and cooling. Succulent plants flourish in the driest soils; and when too much watered they die, but do not produce a proper vegetable mould. The *stapelia*, the *euphorbia*, and *aloes*, do not belong to this order.

The *gruinales* are an association of congenères, without any striking general character. In a medical view the order contains chiefly astringents, as the *geranium*, the *quassia*, and the *simarouba*. The *ros solis* and *acetosella* are acidulous; but it is not uncommon to find an acid evolved in the leaves of astringent plants. This is discovered in the docks, and their congenères, the *rhubarbs*, and these plants are in other parts bitter. The *guaiacum* contains in its bark a bitter and slightly astringent principle.

The *inundatæ*, which live in water only, are insipid, inodorous and not medicinal. The *calycifloræ* contain no medicinal plant; and the *calycanthemæ* one only, now neglected, the *lysimachia purpurea*. It is mucilaginous and astringent, so that perhaps some other genera of this order may merit a trial.

The *bicornes* contain few medical plants, of no very decided character. The *ledum palustre*, *rosmarinus sylvestris*, has alone any odour. The *uva ursi*, and the different species of *vaccinium*, whose berries are chiefly employed, but whose roots are bitter and astringent, as well as the *pyrola*, show the general nature of the *bicornes*. Linnæus is inclined to add the *styrax* and *citrus*. Murray admits the *styrax*, with the *alkanet*, the red and yellow sanders, and the *taniarisk*, with views not correctly medicinal, though the last is a slight astringent.

Of the *hesperideæ* we have no explanation; but we observe the *myrtus*, which affords the *cassia caryophyllata* and the *pimenta*, and the *caryophyllus aromaticus*. To which Murray adds the *melaleuca leucandron*, the source of the *oleum cajeput*. This order is therefore medicinally correct.

The *rotaceæ* have no commentary in Giseke. We perceive them, however, to contain the *anagallis*, the *nummularia*, the *gentian*, and *centaury*, which are all bitter and slightly astringent. Murray adds the *primula veris*, the *cyclamen*, and the *menyanthes* (*trifolium fibrinum*), which are slightly bitter and somewhat fetid. These Linnæus includes with propriety in the following order, the *precieæ*, all of which are without stalks.

The *caryophylleæ* occur only in the elder manuscript of Fabricius. It is of little importance, including only the *pinks*. The only genera used in medicine are the *dianthus* and *saponaria*, both neglected. The last derived a temporary credit from the commendations of Stahl and Boerhaave, who thought to have found a powerful aperient in a plant, which thus contained what they considered as a natural soap.

The *triulideæ* contain the *hippocastanum* and *nasturtium Indicum* (*tropœlum majus*), to which Murray has added the *barberry*, and the *tribulus aquaticus* (*trapa natans*). The bark of the horse chesnut is powerfully astringent, and that of the *barberry* is slightly so. The others have little medicinal power.

The *corydales* contains only the *fumaria*, a plant that, from a cooling bitter taste, has acquired credit in removing visceral obstructions. The *fumaria bulbosa*, which, in former pharmaceutical authors was styled *aristolochia fabacea*, is not very different. This genus connects the *corydales* with the *rhœades*.

The *putamineæ* afford only one medicinal plant, the *caparis*. The gems styled *capers* are known among the *acetaria*; but the root is bitter and acrid, though not astringent.

The 26th order, the *multisiliquæ*, is, in every medical and botanical view, natural. It furnishes the *aquilegia*, the *aconites*, the *delphinium*, including the *calca-trippa* and the *stavisagria*, the *nigella*, the *pæony*, the *hellebores*, the *ranunculi*, the *anemones*, the *flammula jovis*, the *actæa*, the *thalictrum*, and *cimifuga*, with some similar plants. These are all anodynes, or rather narcotics, with different mixtures of a stimulant kind.

The *rhœades* contain chiefly the poppy: the only other medicinal plant is the *chælidonium*, which unites considerable acrimony with narcotic powers, and whose real merits seem to have been little understood.

The *luridæ*, called by Murray the *solanaceæ*, contain all the narcotics, and, in a medical view, should

have followed the multisiliquæ. It contains all the vegetable narcotic poisons, or remedies; a class at present too extensive for enumeration, but which any reader can supply.

The *CAMPANACEÆ* is a very important order. The genus *convolvulus* furnishes five active purgatives, if we except the jalap, now suspected to be the root of a very different plant. The *ipecacuanha* also is known not to be a species of *viola*. The *lobelia* is a more general stimulant and diaphoretic; and the *dentaria*, if its genus is not mistaken, a simple stimulant only.

The 30th order, *CONTORTÆ*, is an important one, as it contains the *cinchona*; yet we find few, and not very active, medicines associated with it. The *vinca peruviana* is undoubtedly an astringent, and employed chiefly in topical hæmorrhages or mucous discharges; and the *nerium antidysentericum*, the *codagapala* of the *hortus Malabaricus*, the *conessi* and *tilicherry* bark of modern authors, is also a topical astringent. The *asclepias vincitoxicum* agrees with neither; and there is little doubt but that the order is not natural, or the *asclepias* improperly arranged. Was there room for disquisitions purely botanical, we could, we think, prove the former to be the case.

The *VEPRECULÆ* are without a comment, and furnish only one genus, the *daphne*, which supplies us with the *mezereum* and *thymelæa*. The *PAPILIONACEÆ* are of greater importance, and they form a natural group even in the sexual system: they are the *leguminosæ* of Ray, the *papilionaceæ* of Tournefort, and the irregular tetrapetalous flowers of Rivinus. In short, the natural relations are so obvious, that they cannot, even by the most hasty observer, be overlooked or mistaken. They afford, however, little subject of medical disquisition, as we shall show by enumerating the principal genera employed in medicine. These are the lupines, the brooms, the beans, vetches, *tragacanth*, *mellilot*, and *fœnugrec*. The *dolichos* may have some medicinal properties, but the setæ of the pod are only employed as a mechanical anthelmintic. The seeds of the broom are acrid.

From the *LOMENTACEÆ* various medicinal plants must now be expunged, since they are found to belong to other genera; yet, in a medical view, the list is very miscellaneous. We find the *cassia*, including the *senna* and the *cassia fistularis*, which are purgatives; the *mirra* and *logwood*, which contain astringents; the *polygala*, of which the *seneka* is a species, that is both emetic and cathartic. The *tamarindus* and *myroxylon*, the supposed source of the *balsamum Peruvianum*, must be excluded. We have already said that the *fumaria* has been added by Murray; and, to a class so miscellaneous, no injury can be offered.

The 35th order, the *SENTICOSÆ*, are astringent, though in a slight degree. The *tormentilla* is the strongest. The principal medicines derived from this order are the *saxifraga*, *ulmaria*, the roses, the brambles, *agrimony*, and some others of weak powers.

The *POMACEÆ* contain the different fruits, as apples, pears, medlars, quinces, cherries, plums, peaches, oranges, currants, &c. The *spiræa*, which produces no eatable fruit, should undoubtedly be excluded.

The *COLUMNIFERÆ* are the *malvacæ* of later authors. They are emollient, and contain the *althæa*, the *malloes*, and the *cacao*. The *cotton* and *abelmoschus* be-

long to this order; but, whatever be their merits in other respects, we have no evidence of their mucilaginous powers. Though the medical plants are few, the list is, on the whole, extensive.

The *TRICOCCÆ* are a strictly natural association, and contain plants of considerable acrimony. The genus *euphorbia* affords the *euphorbium*, *catapotia*, with the greater and less *esula*: the *cambogia* is the supposed source of the *gutta gamba*; the *phyllanthus* affords the *emblic myrobolans*; and the different species of *croton* produce medicines of considerable acrimony. The *casarilla* is the bark of a *croton*, which, in its other portions, appears acrid and poisonous. The different species of *ricinus* afford also very acrid medicines, though the acrimony is sheathed in the oil procured from its seeds. Murray adds green and *bohea* teas; they are certainly *triccocous*, but do not agree with the other botanical or the medical properties of the order.

The *SILIVOSÆ* have been associated by almost every botanist from the time of Morison: they are the *cruciformes* of Tournefort; the *tetradynamia* of Linnæus. They are very generally stimulant. The mustard, the horse radish, the garden nasturtium, with a long tribe of similar plants, belong to this order. They are supposed to be very generally diuretic; and from hence their antiscorbutic qualities are explained: but they possess this power in a very slight degree superior to other vegetables.

The *PERSONATÆ* form a natural medical association, but their powers are weak, and they are at present seldom employed. The *veronica*, *becabunga*, *agnus castus*, *linaria*, and *scrophularia*, are of this order; and from these the virtues of the whole may be easily understood.

The *ASPERIFOLIÆ* are generally mucilaginous and cooling. The *consolida*, the *borage*, *pulmonaria*, *buglossum*, *cynoglossa*, with similar medicines, belong to it. In a botanical and medical view, this order is strictly natural: it was first formed by Cæsalpinus, and retained by Ray. The ancient pharmacutists collected their four cordial flowers from this order, but the virtue was imaginary.

The *VERTICILLATÆ* formed an order also in Ray's system. It is a strictly natural one in a botanical and medical view, and chiefly contains the lighter European aromatics. The various species of *teucrium*, the *thyme*, the *serpillum*, the *melissa*, the *lavender*, the *marjoram*, the *mints*, the *sage*, the *rosemary*, &c. are of this order; and all the plants generally agree in the same powers.

With the order *DUMOSÆ* Linnæus was not satisfied. It includes the larger shrubs, without any very strict botanical views, and we find little union in their medicinal virtues. It contains the *spina cervina* (*rhamnus catharticus*), the *elder*, and the tree that affords the *balsamum copaibæ*. How distant and irreconcilable! The greater number are highly acrid, and many are poisonous: they seem to have some connection with the *triccocæ*.

From the *SEPIARIÆ* we only employ the *jasmine* and the *olive*; and, from their virtues, if any, those of the other genera will be sufficiently obvious. The *syringa* is of this order.

The 45th order, the *UMBELLATÆ*, is a natural one; and the medicinal plants arranged under it are distin-

guished by some acrimony, which at times rises to aroma, as in the carui and coriander; at others, betrays the nauseous smell and taste of the fetid gums; and in some is united to the deleterious smell and powers of the cicuta, which is an umbellated plant.

The *hederaceæ* contain the ivy, the vine, and the gensing, plants united by no medical, and no very striking botanical analogy. The *stellatæ* form a more natural group; yet, in a medical view, not strikingly such. It contains the spigelia, an anthelmintic; the serpentum lignum, a warm sudorific; the madder, the galium, matrisylva, and mungos (*ophiorrhiza-mingos*). The coffee very nearly resembles the plants of this order.

The *aggregatæ* contain the scabiosa officinalis; another species, morsus diaboli; and the viscum, which are astringents; with the valerian, of very different qualities. This order was established by Vaillant.

The *compositæ* is a very miscellaneous order, and, in reality, consists of several sufficiently natural associations. Its distinguishing mark is a single calyx, common to several florets, generally monopetalous. The groups into which this order is divided, are the *capitatæ*, *semiflosculosæ*, *discoideæ*, *oppositifoliæ*, and *nucamentaceæ*. The *capitatæ* are distinguished by a bitterness, with occasionally a warm acrimony. It contains the bardana, the carduus, different species of centaury, the onopordum, the cinara, and the carthamus, with some similar plants. It is not easy to fix the limits between the *capitatæ* and *semiflosculosæ*: the scolymus unites them, for it has the habit of a carduus; yet all the florets are ligulated. In the same way the perdicium, a new genus, unites the inula of the group *discoideæ* with the hieracium, which is one of the *semiflosculosæ*. This second group contains the *oleaceæ* which possess some acrimony, as the cichoreum, the endive, the taraxacum, the lettuce, the scorzonera, and the tragapogon. The greater number are lactescent, but none poisonous except the lactuca virosa, which, however, by cultivation becomes mild and esculent.

The *discoideæ* are styled by some authors *radiatæ*: many of these are slightly bitter, but the bitter is of the narcotic kind; and in several it is in so great a degree, particularly in the arnica and doronicum, as to require the greatest caution. One group which has no title, the following, the *oppositifoliæ* and the *nucamentaceæ*, do not greatly differ in the qualities enumerated; and we may mention, as examples, the artemisia, the tansy, the camomile flowers, the inula, the achillæa, and the arnica. Some are milder, as the colt's foot, the xanthium, the matricaria, &c.; but they all show some acrimony in different parts, and many seem to have an expectorant power.

The *amentaceæ* are the trees distinguished by a particular calyx, styled amentum. If distinguished by any medical quality, it is astringency. The willow, the chesnut, the oak, the hazel nut, all show astringent powers; and there are a few other genera somewhat similar, though less distinguished in this respect. The pistacia affords the Cyprian turpentine, which, with the usual stimulus, seems to unite a tonic power. The mastich, used to preservé the teeth and gums, belongs to the genus pistacia of this order.

The *coniferæ* we have partly noticed in the numer-

ous species of pines under the article *ABIES*. The genera pinus, cupressus, and juniperus, afford the principal medicinal articles under this truly natural order.

The *coadunatæ* scarcely offer any medicinal plant, unless the ilicium anisatum, which affords the anisum stellatum, already noticed, be considered as referable to this order.

The *scabridæ* afford little room for remark, as the plants referred to it scarcely agree in medical virtues. We find the parietaria, the contrayerva, the fig, the nettle, the mulberry, the elm, the hemp, and the hop, of different and almost of opposite powers.

The *filices*, *musci*, *algæ*, and *fungi*, only remain. These are truly natural orders; but of the plants, considered medicinally, we can say little. The ferns are in general slightly astringent. The polipodium, filix fœmina, and mas. are of this kind; and general experience, long before the time of Madame Noufler, has established the utility of the last in the destruction of the tænia. They are all mucilaginous; and the capillary plants, species of the asplenium and adiantum, are also accounted expectorant.

Of the mosses we know little. The lycopodium clavatum is employed externally; the l. selago is peculiarly acrid and violent in its operation. The adiantum aureum is the politrichum commune of the botanist, and a capillary plant, consequently used as an expectorant.

The *algæ* afford the lichen, many species of which are employed. These are in general bitter, mucilaginous, and supposed to be pectoral; but we shall speak at length of the species most used under the title of lichen islandicus. The muscus cumatilis (lichen aphthosus) is peculiarly acrid and purgative. From the latter quality it has been considered as an anthelmintic. Infused in milk, it is given in Sweden to children in the aphthæ. The other algæ agree in no common property, if we except the ashes of the fuci, which, containing the natron and sea salt, are used with success in scrofula. Of the general properties of the fungi we have already spoken. Of their medical powers experience no longer permits us to speak, as they have been long disused.

We have followed this long discussion with anxious care, for the reasons already assigned. From a fair enquiry, we think it will appear that natural associations of medicinal plants in general possess similar virtues; and the principle is confirmed by the circumstance, that the less strictly natural orders, in a botanical view, contain plants most dissimilar in a medical. The conclusion, then, rigorously follows, that by cultivating natural orders we greatly improve our knowledge of the medicinal power of plants. It is this reflection that has led us in appearance so far from our path; and, after having rejected the general botanical details, has induced us to engage at some length in the present disquisition. In fact, it was not in our power to examine medical botany in its most extensive range; we have, therefore, chosen the parts which seemed to admit of the most useful application. We have chosen it, too, though fully convinced of the labour it required, since no prototype existed; and, though the natural orders are now generally pointed out, the subject has not been properly followed in detail.

As we have said, that, in proportion to the more cor-

rect formation of natural orders, medical botany might be further improved, the later attempts in this line would appear to merit some investigation. As Murray has adopted the natural orders of Linnæus with some changes, we have considered his system in a parallel with that of the Swedish naturalist. In these changes we have found something to commend, and much to blame. It is to be regretted that he has not left any disquisition on this subject, and given reasons for his interpolations. A favoured pupil of Linnæus might have communicated many valuable observations on the connection of botany with medicine in this mode of arrangement.

The later system of Jussieu, published in its most perfect form by Ventenat, would too far extend the present article; yet we should not avoid the labour if it were more applicable to medicinal investigation. Jussieu has adopted what is technically styled a method; that is, he has formed classes and orders, as well as a clavis classium. But his orders are extremely numerous, because they are very strictly natural; so that little can be predicated of each order, but what is immediately suggested by the genus. The step, however, which he has thus taken, is highly judicious, as preparatory to the formation of more extensive, and consequently more useful, orders; and, as we found that those of Linnæus contained too numerous, and consequently discordant, genera, so in this system we should see with satisfaction an union of some of the genera most nearly related. Were we to resume this subject in a separate work, we should perhaps be rather tempted to reform the associations of Linnæus, than wholly adopt those of Jussieu. We speak only with a view to the medicinal power of vegetables.

The Swedish naturalist thought highly of M. Jussieu's botanical talents, and of his natural associations. We have seen, in the little dialogue quoted, that he had in his view a *method* which he would not explain; but he has given hints of this method, and it appears to be the same with that of Jussieu. As this must be the foundation of every improvement of natural orders, we shall enlarge a little on it. Natural orders are very intimately connected with the cotyledons, or the lobes, as in the bean, into which the seed is divided. The seeds of the greater number of plants, as we have seen, contain two cotyledons; many contain one only, and the cryptogamiæ chiefly contain none. From the time of Ray, this has been found the part of a vegetable most steady and constant, and that which connects plants similar in form and in virtues. The polycotyledones are only like double flowers, vegetable monsters, produced by an excess of nourishment, and consist in a further division of the lobes of the bicotyledones. Some authors contend, as Gærtner and others, that real polycotyledonous plants exist; but this makes little difference in the arrangement, as there are but few such, and not strikingly distinguished.

Another part of Jussieu's system is connected with the insertion of the corolla. The flower is subject to few varieties, but it is not so constant as the cotyledons. Linnæus attended only to two distinctions, viz. the superior and inferior, when it was above or below the ovary, or seed pod. Jussieu is more minute. It is sometimes inserted *on* the ovary, and is then styled *epigynous*, as in the rubiaceæ and umbelliferæ; some-

times *under* the ovary, when it is styled *hypogynous*, as in the cruciferæ and labiata; and sometimes *on the calyx*, and is then called *perigynous*, as in the rosaceæ and leguminosæ. In this case the flower is rarely monopetalous, though this occasionally occurs, as in the campanulaceæ, and some others. Jussieu has added the following table, to express the importance of each part of the fructifications in forming natural associations. The proportion is expressed by a fraction, of which 12 is the common denominator.

	Presence or absence, - - - - -	9
	Situation with respect to the ovary, - - - - -	10
	Structure, - - - - -	8
	Regularity or irregularity of its border, - - - - -	6
	Presence or absence, - - - - -	10
	Insertion, - - - - -	11
	Structure, - - - - -	11
	Regularity or irregularity of its border, - - - - -	9
	Insertion, - - - - -	11
	Number, connection, and proportion, - - - - -	7
	Free or adhering, - - - - -	10
	Simple or complicated, - - - - -	9
	Present or absent, - - - - -	6
	Simple or complicated, - - - - -	6
	In every view, - - - - -	6
	Present or absent, - - - - -	9
	Consistence, - - - - -	6

	Present or absent, - - - - -	10
	Position with respect to the embryo, - - - - -	9
	Nature, - - - - -	9
	Situation, - - - - -	9
	Direction, - - - - -	8
	In every view, - - - - -	4
	Direction, - - - - -	10
	Situation, - - - - -	9
	Form, - - - - -	10
	Number, - - - - -	12

In this table the only term not generally known is the *perispermum*: it is not a new appellation, though seldom employed. It is that part of ripe seeds distinct from the coverings and the embryo; in many seeds not unlike, both in consistence and colour, the white of an egg. Grew calls it the albumen, and Malpighi, the *secundinæ internæ*.

Jussieu's system is divided into fifteen classes. The first is the *acotyledonous*, the cryptogamiæ of Linnæus, containing an order of hepaticæ added to the usual ones. The *monocotyledones* are divided into three classes, according to the situation of the pistils before explained. The first of these contains the reeds, rushes, and grasses; the 2d, the palms, the lilies, and irises, &c.; and the 3d, the scitamineæ, orchideæ, &c. The *dicotyledones* are divided into three sections, forming ten classes, viz. the apetalæ, monopetalæ, and polypetalæ. These are subdivided according to the attachment of the stamina or corolla. The apetalæ, whose stamina are attached to the pistil, are the asaroids only; to the calyx, the laurels, the proteas, the daphnes, &c.; under the pistil, the amaranthuses, plantagos, &c.

The monopetalæ, whose corolla is attached under the pistil, contain the jessamines, the solanæ, borragos, the gentianæ, labiata, personatæ, &c.; when attached to the calyx, the bicornes, campanulacæ, &c.; when attached under the pistil, with the antheræ reunited, they contain the corymbiferæ, chicoracæ, &c.; with the antheræ distinct, the dipsacæ, rubiacæ, and caprifolacæ. The polypetalous plants, whose stamina are attached to the pistil, contain the araliacæ and umbelliferæ; when attached under the pistil, the tulips, ranunculuses, barberries, poppies, cruciferæ, hesperidæ, malvacæ, sarmenacæ, &c.; when attached to the calyx, the ficoids, the succulentæ, the rosacæ, the leguminosæ, &c. The last class contains the irregular plants, where the stamina are separated from the pistil; viz. the tithymalæ, the cucurbitacæ, urticæ, amentacæ, and coniferæ.

In these fifteen classes, one hundred natural orders are arranged; containing one thousand seven hundred and fifty-four genera. The characters of the genera are simple, and at the same time complete. The advantages of an increased number of characters are considerable, and it is not one of the least, that they are more simple, more easily comprehended and recollected.

The perfection of a natural method, is the philosopher's stone of the botanist. The great obstacle, says Linnæus, is the number of plants not yet known. We have expressed a very opposite opinion, but with a different meaning. Linnæus thought the method, which did not contain every vegetable, imperfect: he spoke of the groups, and the completion of a system, as comprehending the whole. But, as the shades by which nature varies her productions are minute and almost imperceptible, were every vegetable known, we should probably find discrimination into orders difficult, if not impossible. In the most natural orders, the distinction of genera is far from an easy task.

The arrangement of natural orders has occasioned some difficulty. From the varying shades by which these associations change, it has been proposed that they should follow each other according to their affinity. This is, however, difficult, and perhaps not the most convenient plan; for an order may agree with another in some respect, and with a very distant one in others. The idea suggested by Linnæus, and executed, as we have said, by Giseke, is more convenient, viz. to lay them down like countries in a map, when the connection of the whole vegetable kingdom will be obvious. As botanists now do not confine their descriptions to the arbitrary systematic distinctions only, natural systems will be daily more complete, and medical botany, we trust, be proportionably improved.

Though we look, however, to the perfection of a natural system as the best method of assisting our investigation of the medical properties of plants, we have expressed our approbation of an artificial one, as the most ready and convenient method of discovering the place of a vegetable in an arrangement of plants; and, of course, of obtaining a ready access to its synonyms. For these reasons we have identified the medicinal plants by a reference to the Linnæan system; and it remains to give some explanation of the principles on which the northern Pliny proceeded in constructing it.

Linnæus was very early persuaded of the distinction of sexes in plants, a question now no longer disputed;

for the last dart of Spalanzani 'rung, ineffectually tinkling on the shield.' The male organs he supposed to be the stamina; those upright filaments which, in a tulip or a lily, stand around a central column, bearing orange coloured bodies, the *antheræ*. The central column is considered as the female organ, and styled the pistil, and its summit is the *stigma*. In the Linnæan system the first ten classes are distinguished by the number of the stamina, and styled *monandria*, *dian-dria*, &c. from the number of the *aveses*, or males. No vegetable contains eleven stamina, so that the eleventh class is distinguished by twelve *dodecandria*. The two next are those that contain twenty, or more than twenty, stamina, *icosandria* and *polyandria*; but in these greater numbers there is not always a regularity, so that the attachment of the stamina to the calyx is afterwards superadded. The unequal length of the stamina distinguishes the two next classes. When of four, two are longer than the others, the class is styled *didynamia*, the superiority of two; when of six, four are longer, *tetradynamia*, the superiority of four. When the *filaments* of the stamina are united into one body, the class is styled *monadelphica*; when into two, *diadelphica*; when into many, *polyadelphica*, the brotherhood of one, two, or many; when united by the antheræ, the class is *syngenesia*. When the stamina are attached to the pistil, the class is *gynandria*.

The sexual organs are sometimes found on different flowers of the same plant, sometimes on different plants. These furnish the *monæcia* and *diæcia*, a single or a double house. Sometimes they are found more indiscriminately, mixed with flowers which contain in one the organs of both sexes; and the class is then styled *polygamia*, many marriages. The last class contains the plants which have no visible flowers, the flags, the ferns, the mosses, and mushrooms; these are united under the class *cryptogamia*, concealed marriages.

Of these classes very few are natural: the *tetradynamia* and *monadelphia* are very nearly such. The *diadelphia* and *syngenesia* do not contain many discordant plants.

The orders of the first thirteen classes are taken from the central column, which is not always a single one; and are styled *monogynia*, *digynia*, &c. from *γυνή*, a woman. The orders of the *didynamia* are distinguished by the seed being naked or covered; of the *tetradynamia*, from the seed pod.

The classes distinguished by the connection of the stamina, are divided into orders from their number: those where the antheræ are connected, from circumstances somewhat fanciful, but of little importance to explain. The orders of the *gynandria*, *monæcia*, and *diæcia*, are taken from the number and connection of the antheræ, or their situation. Those of the *polygamia* from the flowers being on the same, or on different plants. The orders of the *cryptogamia* are the natural families formerly mentioned; and to these Linnæus adds the natural family of the *palmæ*.

Of the numerous vegetables thus arranged, but few are used in medicine; and it has been for ages the subject of declamation, echoed from mouth to mouth with little change, and with little discrimination, how improperly we employ chemical medicines which the stomach cannot assimilate, instead of vegetables which are subservient to its power. We are not yet

prepared to discuss this question; yet we have already found that the vital fluid is seldom greatly changed in the most violent diseases; and in many no change has been even suspected. The great sources of disease are the excess and diminution of motion, or irregular action; producing either spasmodic paroxysms, or a derangement of the balance of the circulation. In a few instances only are the fluids affected; and in the greater number of these the fault is corrected by exciting the action of the moving powers, rather than amending the supposed deterioration. Yet we mean not to reject or undervalue vegetable medicines: in many instances they are our great support. Nor can we find, in the mineral kingdom, medicines equal to ipecacuanha, to rhubarb, the different aromatics, and, perhaps, the bark. Were we to pursue the list, it would not, however, fill many lines. In a vignette to the *Materia Medica Contracta* of Tessari, though we believe the original idea was Haller's, we see two boys holding the 'sieve of truth.' Opium, castor, and bark, only fall through; the rest are retained, even the radix senekæ; and cinabar is seen apparently forcing a passage.

We had designed to add a table of the medicinal plants as arranged in the Linnæan system; but it would fill some pages without any adequate advantage; as it would only be more clearly seen what discordant properties are thus violently brought together, and how distant, plants very similar in their powers, are placed. This, however, from what we have already stated, is no argument against the Linnæan arrangement. The natural and artificial systems may mutually assist and illustrate each other; and each, in turn, be employed with advantage.

**BOTA'NICON**, (βότανη, *herba*). The name of a plaster described by P. Ægineta, and made of herbs.

**BO'THOR**, (Arabic,) hath three significations among the Arabians. 1. Tumours in general; 2. A tumour with a solution of continuity; and 3. Small tumours, which is the most correct interpretation. It has been supposed to signify an abscess of the nostrils, or transitory pimples in the face. The Arabians call the *small pox* and *measles* by this name.

**BO'THRION**, vel **BO'TRION**, (in Greek, βόθριον, *a little pit*). A SMALL PIT, (from βόθρ, *a ditch*). This word is used to express a small clean ulcer of the cornea, equal to the head of a pin, called also *cæloma*. If it should be an internal lamina of the cornea, it creates the disease called *gerontoxon*, and a staphyloma succeeds. See Sauvages' *Nosologia Methodica*. Also the *alveoli*, or sockets of the teeth.

**BO'TIN**. See **TEREBINTHINA**.

**BO'TOU**, **BO'TOUA**. See **PAIREIRA BRAVA**.

**BO'TRIA**. A plant found on the coast of Africa. Its berries are eaten as food, and a decoction of its roots recommended in internal inflammations of the breast. It resembles the pareira, but its botanical relations are not fully known.

**BOTRITIS**, **BOTRYITES**. **BOTRITES**, (from βότρυς, *a cluster*, properly of grapes). See **CADMEA**.

**BO'TRYS**. The following are generally considered as species of botrys.

**Bo'trys**. The oak of CAPPADOCIA or of JERUSALEM; also called *artemisia*, *ambrosia*, *chenopodium*, and *atriplex odora*, or *suaveolens*. It is the *chenopodium botrys* Lin. Sp. Pl. 320.

**Bo'trys MEXICA'NA**. The **MEXICAN TEA**. Called also *botrys ambrosioides Mexicana*, *chenopodium Mexicanum*, *botrys Americana*, *Spanish tea*, and *Aretmisian botrys*. *Chenopodium ambrosioides* Lin. Sp. Pl. 320.

These plants are natives of the southern parts of Europe; they are sown annually in our gardens. The leaves and flowery heads have a strong but not unpleasant scent, are aromatic and acrid to the taste. If they are much handled, an unctuous resinous juice adheres to the fingers.

The proper menstruum for their active matter is rectified spirit of wine; but boiling water also takes up the greatest part of their virtue. An infusion drunk as tea is useful in palsy, weakness, coughs, and humoral asthmas. The seeds are said to be carminative and anthelmintic. They are ranked among the antispasmodics: the former is the weakest.

**BO'TUS**, **BO'TIA**, or **BO'TUS BARBATUS**. It is a chemical vessel, called a *cucurbit*, (see **CUCURBITA**); also a vessel placed upon a vessel; a vessel for fusion, or a *desensorium*; a chemical furnace in which distillation is performed by descent; a crucible.

**BOUBA'LIOS**. See **CUCUMIS AGRESTIS**, and **PUDENDUM MULIEBRE**.

**BOU'BON**. The Greek word from whence **BUBO** is taken, (see **BUBO**). It signifies the groin, sometimes the glands in the groin; and a tumour of the glands in the neck, arm pits, behind the ears, or of any external glandular part.

**BOU'CERAS**, (from βας, *an ox*, and κερως, *a horn*). So called from the figure of the seed. See **FENUM GRÆCUM**.

**BOUGI'E**, in the French language, means a *wax candle*. The term is applied to a body of a similar shape, introduced into the urethra for removing obstructions. It is likewise known by the terms *catheter*, *candela cerea*, vel *medicata*. A wax candle was formerly employed; and from the name, it seems to be a French invention. It was described previous to the appearance of syphilis.

In Dr. Swediaur's *Pharmacopœia Syphilitica*, *bougies* are called **CATHETERES**, first made of silver, but they are better formed of elastic resin of various sizes. The second he styles **CATHETERES CEREI**, of elastic resin, or of musical chords, made from the intestines of sheep. The third are **CEREI MEDICATI**, made in the following manner:

R. Ceræ flavæ liquefactæ lb i. spermatis ceti, ʒ iij. aquæ lythargyri acetati, Ph. Lond. nov. ʒ ij.—ʒ i: these when mixed together are removed from the fire, and slips of linen cloth are to be dipped in the composition, to be rolled into the form of a wax taper.

The fourth are the **CEREI MEDICATI**, known long before the time of Le Dran.

The great object to be attained by the bougie is mechanical pressure equable on all sides. We do not now expect to gain any advantage by introducing mercury in this way into the system, or to cure any ulceration. The preparation is therefore simple; and the cloths of which they are composed, are chiefly impregnated with wax and oil, rendered somewhat firmer by a proportion of resin. Some saturnine preparation is generally added, as the urethra is in an irritable state, and the mechanical irritation might otherwise increase it.

From whatever composition the bougies are made, they must be of different sizes, from the knitting needle to a goose quill. The common ones are made in the following manner. Having spread any quantity of linen rag with the composition that is chosen for the purpose, cut it into slips from six to ten inches long, and from half an inch to an inch broad; then dexterously roll them on a glazed tile into the form of a wax candle. As the end of the bougie which is first introduced into the urethra should be somewhat smaller than the rest, the slips must be cut a little tapering; and when the bougies are rolled up, that side must be outward on which the plaster is spread.

Mons. Daran, and some others, attributed the action of their bougies to the composition used in forming them. Mr. Sharpe apprehended that their efficacy was chiefly owing to their compression on the affected part; and Mr. Aikin adds, that as bougies of very different compositions succeed equally well in curing the same disorders in the urethra, it is plain that they do not act from any peculiar qualities in their composition, but by means of some common property, probably their mechanical form.

The efficacy of mere compression in many cases of constriction is well known, from the use of sponge tents for dilating parts straitened by cicatrices. If, then, obstructions in the urethra arise from a constriction formed by cicatrised ulcers, or a projection of the spongy substance of the urethra into the canal, we may easily conceive that a gentle continued compression will, in time, overcome the disease. We may also readily account for the inferior efficacy of metallic, whalebone, and leather bougies, from their not having the property of swelling with moisture, and therefore not making an equal compression.

There is no doubt but the mechanical stimulus of a foreign body in such a tender part, though free from disease, must produce in some degree a discharge of matter, and this will be varied according to the chemically stimulating quality of the composition, and the irritable state of the urethra; but it seems an absurdity to apply an uniform cause of distention to the whole length of a canal, with a view of producing extraordinary effects upon a particular part, by means of some powerful quality in the ingredients. That part of the bougie which was in contact with the diseased part is certainly covered with matter; but this circumstance is owing to the greater irritation of the urethra there than in the other parts. To forming *bougies* of very active materials there certainly exists a very proper objection; because the healthy as well as the diseased parts are exposed to their action, and may themselves become diseased by the application. Surgeons, therefore, have confined themselves to the simple kinds, and such as act chiefly by compression.

Plenck recommended bougies of catgut, which may be easily introduced even into an urethra greatly contracted, as the size is small, the substance is firm, and as it dilates with moisture. They are not, however, convenient; they dilate below the stricture, give great pain when withdrawn, and do not dilate sufficiently on the contracted part.

The elastic resin has been employed for this purpose with great success, as it unites firmness and flexibility, but perhaps it does not swell sufficiently. The resin

is moulded on catgut in a way kept secret. They are, however, in many cases highly serviceable, though their surface soon becomes rough, and they are expensive.

Mr. Smyth, apothecary, of Tavistock street, has discovered a metallic composition of which he forms bougies, which are allowed to possess properties that these instruments have long wanted, in order to make them complete and efficacious in practice. Bougies formed of this metallic substance are flexible, have a highly polished surface of a silver hue, and possess a sufficient degree of firmness for any force requisite for the passing them in cures of strictures in the urethra. Indeed the short time which they have been employed has convinced practitioners that they exceed any bougies which have yet been invented, and are capable of succeeding in all cases where the use of such an instrument becomes necessary. They are made either solid or hollow, and answer extremely well as catheters; for they not only pass into the bladder with ease, but may also be suffered to continue there for any convenient space of time, and hence produce the most essential benefit. Catheters are also made of the same composition. They certainly do not swell with moisture, but they do not break or bend.

See Sharp's Critical Enquiry, ch. iv. and Aikin's Observations on the external Use of Preparations of Lead. Bell's Surgery, vol. ii. 201, &c. and White's Surgery, 371.

BOUI'. (Chinese). See THÆA.

BOU'LIMUS. A VORACIOUS APPETITE; (from βρ, a particle which, in composition, augments the sense, and λιμος, hunger). *Boulimos*, or *bulimus*, for which word Avicenna uses *bolismus*, signifies an ox's appetite, though this disease is more frequently called *fames canina*, or *appetitus caninus*; a CANINE APPETITE: it is also called *phagedæna*, *adephagia*, *bulimia*, *bupheina*.

Dr. Cullen names this genus of disease *bulimia*. He places it in the class *locales*, and order *dysorexia*; and distinguishes three species. 1. *Bulimia heluonum*, in which there is no other disorder of the stomach than an excessive craving of food. 2. *Bulimia syncopalis*, in which there is a frequent desire of food, and the sense of hunger is preceded by swooning. 3. *Bulimia emetica*, also *cynorexia*, in which an extraordinary appetite for food is followed by vomiting.

In some it may be a natural misfortune; for on dissection it hath been found, in a few instances, that the right orifice of the stomach was too large, consequently the aliment was too soon expelled through it. Galen says it is caused by an intense acid in the stomach, or other acrimony in the gastric juice. Others attribute it to a weakness in the lower orifice of the stomach, or to worms.

The complaint was perhaps more common formerly than at present, since the ancient authors consider it with great apparent anxiety. The cause of hunger, in general, we shall find to be an emptiness of the stomach, inducing an uneasy contraction. An increase of this contraction may arise from a rapid digestion, from a weakness of the stomach, or perhaps from worms. The food is retained in the stomach by its contraction, raising the larger curvature of the stomach to an horizontal position, and thus rendering the escape of the food from the pylorus difficult. In this way, weak-

ness may occasion imperfect digestion, and, of course, insatiable hunger; but this cause may be easily ascertained by the lenteric discharge. Indeed, we believe it seldom occurs, and acids scarcely in any instance produce the complaint. From worms we have, we think, seen this disease: but we own that this cause is doubtful, for a plain and obvious reason, that no known species of worm lives on a chylous fluid, and the general effect of worms is irritation.

Lommius observes, that in this case there is great hunger, much is eaten, which, oppressing the stomach, is again thrown up; the patient is thus relieved, but the appetite returns; the stomach eased, by eating is again oppressed, and is again relieved, as that of a dog by vomiting.

There is no danger if food is supplied, though the patient be pregnant, except fainting is frequent. Fainting, with a full stomach, is a dangerous symptom; and the breath failing when a fainting comes on, adds to the danger: but these appearances are uncommon.

If an acid should be the cause, after vomiting, the testaceous powders, the lixivium of tartar, and iron filings, have been given.

If worms are suspected, anthelmintics must be prescribed; and in every instance, food of a less nutritious kind should be employed.

When the cause is not very manifest, moderate doses of opium may be given at proper intervals; but some circumspection is required in administering it. Besides vomiting, purges with aloes will be adviseable, wormwood, and such other medicaments as warm and strengthen the stomach. Galen commends frequent small doses of brandy; and Riverius says, that ambergris is peculiarly useful if five or six grains be repeated at due intervals; and coffee we have found of great service.

This disorder terminates in a lientery, dropsy, atrophy, or cachexy. Boulimus, it is said, is not attended with a vomiting, but with a fainting; and that in the FAMES CANINA, the patient vomits up his greedy meals, or they run off by stool. In the BULIMIA, it is remarked, the same inclination to eat exists as in the BOULIMUS, but without the power; and after the patient does eat, he faints. See Galen, Alexander Trallian, Paulus Ægineta, and Lommius.

BOU'NIAS, (from *βουνος*, a bunch). See BUNIAS.

BOU'RSE, LA. See SUSPENSOR.

BOUTU'A. See PAREIRA BRAVA.

BOVILLÆ, (from *βες*, an ox). The MEASLES: so called because cattle were supposed subject to it. Turton says, it may perhaps rather mean the cow pox. See MORBILLI.

BOVINA AFFE'CTIO. The DISTEMPER OF BLACK CATTLE. A disease among black cattle, caused by a worm lodged between the skin and the flesh. The Arabians call it *agritudo bovina*, but it is little known in Europe; is not mentioned by the ancient Greeks, and differs essentially from the disorder produced by the *dracunculi*.

Avenzoar gives the following account of the *bovina affectio*. 'Sometimes a worm breeds between the skin and the flesh; and if this worm is not soon killed, the consequences may be pernicious. As soon as it is perceived, burn the adjacent part with a hot iron, so that heat may penetrate to the worm, in a degree sufficient

to kill it. Then dress, as is usual after burns, and purge with aloes.'

Avenzoar in this passage speaks of this disorder as in human subjects. But Albucasis, who hath two chapters, one on the *dracunculi*, another on the *bovina affectio*, says, 'This worm, which is generated between the skin and flesh of black cattle, takes its course over the whole body, and is plainly perceivable in its motion from one part to another, until it breaks the skin; and wherever it makes a breach, there it finds egress;' evidently confounding it with the gordius. Alzaravius says, 'that in human subjects this worm passes betwixt the skin and the flesh, as Albucasis hath represented it in brutes; and that it is generated in the same matter as lice.'

The real *bovina affectio* is described in a dissertation, De Boùm Œstro, by Wallsinerius. This ŒSTRUM, or VEXATIOUS FLY, pitches on the back of black cattle, and, with a kind of sting growing to its hinder part, perforates them, and into each perforation introduces an egg, which some time after grows to a worm, and this to a fly, which in due season is like its parent. When this fly pierces the skin, it causes severe pain in the oxen. The worm, however, which is deposited, grows without any remarkable injury to the health of the animal; it never moves from its place, but in the following spring it occasions a tumour, out of which it finds its way when summer approaches, and becomes a fly. See Le Clerc Hist. Lumbric, Linnæan Transactions, vol. iii. p. 289.

Under this article may be placed the CHICOS, or CHIRCRES. They are small worms, which, in the warmer parts of America, frequently breed in the muscular parts, and particularly in the feet. The Indians pick them out, and then apply to the sore, by rubbing, the ashes of wood.

Hoffman speaks of a kind of worms to which the children in Misnia are subject. He says that these children are frequently seized with a tabes, which reduces them to mere skeletons. The cause is a sort of worms, like black hairs, lodged under the skin. These animals are usually called COMEDONES, or gluttons, because they devour the nutritive juices in their distribution. When the skin is rubbed with honey in any warm place, they come out, but cold keeps them concealed within. The disease is apparently eruptions, from dirt, neglect, and low living. See CRINONES.

Sennertus speaks of a sort of worms called *seurennes*, *sirenes*, or *crinones*. He tells us, that a species of pustules among the Germans, which rise on the palms of their hands and the soles of their feet, are called *seuren*, and contain little worms called *sirones* and *chirones*: that these worms are discovered by the itching of these parts.

BOVI'STA. See LYCOPERDON.

BO'XUS. See VISCUS.

BRA'BYLA, (quasi *βοροβαλα*, i. e. την βοραν εκβαλλοντα, because they are laxative, and clear the intestines of their contents). The plums which are called HUNGARIAN. They are large, sweet, and of a black colour.

BRACHE'RIUM: AM'MA. A surgeon's bandage and truss for a hernia. A word used by the barbarous Latin writers, probably from *brachiale*, a bracelet. It is so called because it is made to embrace the parts.

**BRACHIÆ'US MU'SCULUS.** The name of two muscles of the arm, (from *brachium*, an arm).

**BRACHIÆ'US INTE'RNUS** begins where the deltoid muscle ends, covers the interior and anterior surface of the os humeri, and is inserted into the coronoid process of the ulna, serving to bend it.

**BRACHIÆ'US EXTE'RNUS** seems to be the third beginning of the gemellus; its origin is continued from above the middle of its insertion, and from the back part of the os humeri to the cavity which receives the olecranon in the extension of the cubit, where, joining with the tendinous outside of the gemellus, it is inserted into the superior and external part of the ulna, called olecranon. See **ANCONÆUS**. Cowper.

Douglas says, that the *brachiæus externus* and the *gemellus* make but one single muscle with three heads, to which he gives the name of *triceps cubiti*, or *extensor cubiti magnus triplici principio natus*.

**BRACHIA'LE.** The word means a bracelet; but the ancient anatomical writers apply this term to the carpus, the part on which the bracelet was worn. See **CARPUS**.

**BRACHIA'NIS ARTERIA.** The **BRACHIAL ARTERY**. It is the continuation of the axillary artery, which, as soon as it has passed behind the tendon of the pectoralis major, receives the name of *brachial*. It runs down on the inside of the arm, over the *musculus coraco brachialis* and *anconæus internus*, and along the inner edge of the biceps behind the vena basilica, giving out small branches as it passes.

Between the axilla and the middle of the arm it is covered only by the skin and fat, but afterwards it is hid under the biceps, and runs obliquely forward as it descends, at some distance from the internal condyle; but it does not reach the middle of the flexure of the arm. Below the fold of the arm it divides into the cubitalis and radialis.

From its upper and inner part it sends off a particular branch, which runs obliquely downward and backward, over the *anconæus*, and then turns forward again near the external condyle, where it communicates with a branch of the radial artery. A little below the insertion of the *teres major* it sends off another branch, which descends, is united with the radial artery, and with the cubital.

The common trunk of the brachial artery having reached the flexure of the arm, runs, together with a vein and nerve, immediately under the aponeurosis of the biceps, and passes under the vena mediana, detaching branches on each side to the neighbouring muscles.

Sometimes, though very rarely, the brachial artery is divided from its origin into two large branches, which run down the arm, and afterwards on the fore arm, where they are called cubitalis and radialis. Winslow.

**BRACHIA'NIS EXTERNUS** and **INTERNUS**; these are the **BRACHIÆUS EXTERNUS** and **INTERNUS**.

**BRACHIO-CUBITA'LE LIGAME'NTUM.** The expansion of the lateral ligament (see **LATERALIA LIGAMENTA**), which is fixed in the inner condyle of the os humeri, runs over the capsule, to which it closely adheres, and is inserted like radii on the side of the great sigmoid cavity of the ulna: it is covered on the inside by several tendons, which adhere closely and seem to strengthen it. Winslow.

**BRACHIO-RADI'ALE LIGAME'NTUM** is the expansion of

the lateral ligament (see **LATERALIA LIGAMENTA**), which runs over the external condyle of the os humeri, and is inserted round the coronary ligament, and from thence all the way down to the neck of the radius, and also in the neighbouring parts of the ulna. Through all this passage it covers the capsular ligament, and is covered by several tendons adhering closely to both. Winslow.

**BRACHIUM**, (from *βραχys*, short; because in a well proportioned man it is shorter from the shoulder to the hands than from the hips to the feet. Festus). The **ARM**. In Hippocrates it signifies what is now called the *humerus*. From the shoulder to the elbow, is called *lacertus*; to the wrist, *cubitus*, or the *fore arm*. By the *arm* is generally meant the whole, from the shoulder to the wrist.

**BRACHU'NA.** See **SATYRIASIS**, and **FUROR UTERINUS**.

**BRACHYCHRO'NIUS**, (from *βραχys*, short, and *χρονος*, time). An epithet of a disease which continues but a short time.

**BRACHYPNŒ'A**, (from *βραχys*, short, and *πνέω*, to breathe). **BREATH** fetched at short intervals.

**BRACHY'POTÆ**, (from *βραχys*, small or short, and *ποτῶ*, drink). **LITTLE DRINKERS**. To drink but little in ardent fevers is a sign of insensibility, and consequently bad.

**BRA'CHYS**, (from *βραχys*, short). See **BREVIS**.

**BRACIUM.** See **Æs**.

**BRADYPE'PSIA**, (from *βραδys*, slow, and *πενω*, digero). **WEAK DIGESTION**, or concoction of food. Blacard says, it is a slow digestion, proceeding from a depraved disposition of the acid ferment in the stomach. Its causes are various, but there is little reason for admitting that just mentioned. In general it arises from weakness. See **DYSPEPSIA**.

**BRA'GGAT.** See **HYDROMELI**.

**BRAN.** The husk of wheat separated by sieves. It contains a gluten like that of animal substances, and has been used as a pectoral, a demulcent, and a detergent. It is chiefly useful in the two former views used in decoction.

**BRA'NCA.** An Italian word signifying *foot*; hence a species of acanthus is called **BRANCA URSINA**, *bear's foot*, from the resemblance of its leaves to the foot of a bear.

**BRA'NCA LEO'NIS**, or **PES LEO'NIS.** See **ALCHIMILLA**.

**BRA'NCA URSI'NA.** See **ACANTHUS**.

**BRA'NCA URSI'NA GERMA'NICA.** See **PASTINACA**.

**BRA'NCHÆ**, **BRA'NCHI**, (from *βρεχω*, to make moist). Names of the diseases of the glandular tumours of the fauces, which resemble two almonds; accompanied with a difficulty of spitting and troublesome breathing.

**BRA'NCHUS**, (from the same). A **DEFLUXION** of HUMOURS upon the FAUCES. It is a species of catarrh, which Cœlius Aurelianus calls **RAUCITAS**.

**BRANDY.** It is a spirit distilled from wine, or, more often, from the mock after the wine has been pressed out. In Spain it is often produced from the plum; and in England it is imitated by giving to any spirit a yellow colour by burnt sugar, and a flavour by laurel leaves. In medical powers it agrees with alcohol. The various methods of trying the strength of brandies are

fallacious, and the hydrometer in its most improved state is the only certain method of ascertaining it. See *Annales de Chimie*, vol. xxxvii.

BRASILIA, produced in Brasil. See BRASILIUM LIGNUM.

BRASILIANA ARBOR AQUATICA. See ANINGA.

BRASILIE'NSIS ARBOR SILIQUOSA, &c. See COURBARI'L.

BRASILIE'NSIS RADIX. See IPECACUA'NHA RADIX.

BRA'SILIS LIGN. BRASILE'TTO. LOGWOOD, also RED WOOD. See CAMPECHEN, LIGNUM.

BRASILIUM LIGNUM. BRASIL WOOD; called also *pseudosantalum rubrum*, *Hirapitanga Brasiliensis*, *ibirapitanga*; *Abelicea*, *crista pavonis coronillæ folio*; *Elythoxylum Brasilianum*, *Santalus Adulterinus*.

This wood is rarely met with in prescriptions; it is sometimes substituted for red sanders, with which it agrees in most of its properties, with this difference, that the red sanders does not, like this wood, give out its colour to water. It is of a deep red or purple colour; is said to cool and strengthen; but is chiefly used by the dyers.

From the Brasil wood of Pernambuco is extracted, by means of acids, a CARMINE.

BRA'SIUM, (from *βρασσω*, to boil). BARLEY, or COMMON MALT. Called also *byne*; by Tacitus, *frumentum corruptum*. From it, BEER, ALE, and PORTER, which go under the general term, MALT LIQUORS, are made (see ALLA); but an infusion of malt, called WORT, is considered as powerfully antiseptic, and has been successfully given in the sea scurvy. It is prepared in the following manner: "Take of dry sound malt, fresh ground, one measure: infuse it for five, or six hours, in three measures of boiling water, then pour off the clear liquor," and let the patient drink two or three pints every day. This has been administered as a preventive of the scurvy with some apparent efficacy; and it has been considered as an alterative, in cases of inveterate ulcers and in cutaneous eruptions, which resist the action of mercury. It may be of service where a permanent change in the state of the animal fluids is required; and from its being so grateful, it is preferable to the scorbutic juices given for this purpose. See Macbride's *Experimental Essays*, Appendix to his *Introduction to the Theory and Practice of Physic*.

BRA'SMA, (from *βρασσω*, to boil). See PIPER LONGUM.

BRA'SMOS, (from the same). See FERMENTATIO.

BRASSADELLA, or BRASSA'TELLA. See OPHIOGLOSSUM.

BRA'SSICA, (from *βρασσω*, or *βραζω*, to devour.) CABBAGE; called also *crambe*, *brassica oleracea* Lin. Sp. Pl. 932. All the species are supposed to be only varieties of the smaller kind, which grow spontaneously on our sea coasts. The white and green cabbages are called *caulo rapum*.

Cabbages are supposed to have a stronger tendency to putrefaction than most other vegetable substances; chiefly because in putrefying they exhale an offensive smell, which much resembles that of putrefying animal bodies; it may therefore seem reasonable to believe that they are easily digested in our stomachs, and also

very nutritious. This, however, is by no means true. All of them, says Dr. Cullen, may be considered as a supplemental provision only, and are seldom chosen by the quantity of nourishment they afford, but by the tenderness of their texture, and the fulness and sweetness of their juice. In general they are flatulent, and inconvenient in weak stomachs.

Cabbages are, however, far from being unsalutary; they neither induce nor promote a putrid disposition in the human body, but, on the contrary, are salubrious aliment in the scurvy. They loosen the belly when eaten freely, and produce much flatulency; but by boiling they lose their laxative quality. The *brassicæ* have great powers as antiscorbutics, and taken in largely as aliments have proved a cure for the scurvy.

The Germans make the following preparation of cabbage, to which they give the name *Sauer Kraut*. SOUR KROUT.

Cut the cabbages in common use into thin slices, put them into a cask that is previously cleaned, dried, and lined in its whole inside with the sour paste called leaven; on each layer of the sliced cabbage sprinkle a small handful of salt, and press it down: when as much is put into the cask as it will contain when thus forcibly pressed, and all the liquor squeezed out of the cabbages is poured off, cover it with a clean cloth, then lay on it the loose cask head, and over it any heavy weight, that the pressure may be continued; thus, let it stand in a warm room until it ceases to ferment, and then it is fit for use. When used, boil a proper quantity for the present meal in water during two hours or more; then, pouring off the liquor, add to it a little butter, and eat it as other vegetable substances.

If the cask is closed up when the fermentation of the cabbage is finished, this preparation will be preserved in its perfection many years, and would be a convenient part of seamen's diet, as a preservative from the scurvy.

The white sort is the most putrescible and fetid; the red is supposed to be the sweetest, most emollient, and laxative: there is, however, little difference. If the stalks of the red kind are cut longitudinally in autumn and placed in a cool shade, a laxative juice, resembling honey or manna, exudes from the incisions.

BRA'SSICA SATIVA. COLEWORT or CABBAGE, named also *brassica capitata alba vel rubra*; *b. oleracea*, var. γ δ.

BRA'SSICA FLO'RIDA. CAULIFLOWER, called also *brassica multiflora*, *caulis florida*; *b. olerac.* var. ι.

BRA'SSICA CONGYLO'DES. TURNIP CABBAGE, called also *brassica caulorapa*, *rapocaulis*, *brassica caule rapum gerens*; *b. oleracea* var. λ.

The seeds yield, by expression, an oil which is useful for lamps, and in the woollen manufactory. After the oil is obtained, the remains are an indifferent food for cattle. In their recent state, however, sheep, and even oxen, are fed on them during winter.

BRA'SSICA CAPITA'TA VIRE'SCENS ITA'LICA CRI'SPA. GREEN BROCOLI.

BRA'SSICA RUGO'SA, LONGIO'RIBUS FOLIIS. BROWN BROCOLI. These are varieties of the brassica of little importance, chiefly belonging to the *b. oleracea botritis*; var. ι.

BRA'SSICA NAPUS, NAVEW, or COLE; *radice caulescente fusiformi*. See BUNIAS.

BRA'SSICA ERUCA. See ERUCA.

**BRA'SSICA ITA'LICA TENE'RRIMA GLOMERO'SA FLO'RE A'LBO.** TABAUDE. The SAVOY CABBAGE.

**BRA'SSICA OLERACEA ARVENSIS;** from whose seed the oil styled *CALSA* is expressed. *B. rapa* is the TURNIP. See *RAPA*.

**BRA'SSICA MARI'TIMA**, called also *soldanella maritima minor*, *convolvulus maritimus minor*, *maritimus nostras*. SEA BINDWEED, SEA COLEWORTS, and SCOTCH SCURVY GRASS. The *convolvulus soldanella* Lin. Sp. Pl. 226. It grows wild on the sea coast in the north and south of England, and flowers in June. The leaves are a violent cathartic; and this quality resides in the milky juice which exudes upon wounding them. A decoction of the dried leaves, from 3 ss. to 3 iij. is a dose.

**BRA'SSICA BRASILIANA.** Caspar Bauhine. *Arum esculentum*.

**BRASSIDE'LICA ARS.** A way of curing wounds, mentioned by Paracelsus, by applying the herb *brassadella* to them. See *OPHIOGLOSSUM*.

**BRA'THU.** The herb SAVINE. See *SABINA*.

**BREAD.** This 'staff of life' is now essential to our existence; yet, while we enjoy it, we are naturally led to consider the substitutes once employed, when it was not known. Man, we have said, is not wholly a carnivorous animal: he requires a proportion of vegetable nutriment; and this, in seasons not adapted for vegetation, or in climates when the short summers will not admit of corn ripening, must be supplied by various other vegetable substances. All the farinaceous plants have been used as corn. The palms, the bread fruit tree, the arum, the fern root, and the sweet acorn, have in turn supplied different nations with the necessary vegetable aliment. Besides these, various nations have employed the SEEDS of the *spergula arvensis* Lin. Sp. Pl. p. 630, of the *agrostemma githago* (624), and the *lychnis segetum* of Caspar Bauhine; the NUTS of the *hippocastanum*, the chestnut; the FÆCULA of the cassada (*jatropha manihot* Lin. 1429), Stachy's *palustris* (811), and *lichen islandicus* (1611); the BARK of the *pinus sylvestris* (1418); the roots of the *solanum tuberosum* (265), white bryony (1438), *spirea filipendula* (702), *colchicum autumnale* (485), *fumaria bulbosa* (983,  $\beta$  and  $\gamma$ ), *gramen repens* (128), and *scirpus maritimus* (74). Many other substances, apparently farinaceous, are mentioned by Dr. Willich and Dr. Darwin. But, by general consent, in civilized countries, where the seasons, by the most artful management, can ripen the different cerealia, these have been preferred. Even in the short northern summers, where the sun can barely bring forward the ears, they are ripened not imperfectly by frost. When vegetation can no longer supply corn, even dried fish are powdered, and produce a substance not liable to rancidity; and at least approaching farina. In some countries, particularly in Upper Lusatia, a white earth is employed for this purpose.

The importance of corn was so strongly felt, that the inventive Greeks appropriated its first introduction to a goddess. They chose for its patroness the mother of the gods; but, by an inconsiderate anachronism, associated with her a person of a much later era, Triptolemus. The fable, in fact, meant that the discovery was a very early one, but that it was only communicated to the Grecians at a later period. Naturalists have, on their side, anxiously investigated the native country of wheat, but with little success. The fairest claim is

offered by Sicily, as the Grecian fable would suggest; but, after every inquiry, it appears that native wheat is a comparatively small corn, containing an inconsiderable proportion of farina; and that the present seed is produced from a plant greatly meliorated by culture. When we speak of the native country of corn, we of course mean that country from whence it was anciently derived. We have now discovered it in other regions, with which the ancients were unacquainted.

Under the article of corn we shall mention the different seeds employed to make bread, and distinguish their peculiar properties. We shall now notice only the general properties of the farina used for aliment, with the changes produced in the process of making bread. Meal separated from the bran, or at least separated in a considerable degree, contains a mucilaginous and a saccharine matter, though in a small proportion. The greatest quantity is a fæcula, styled starch, which combines with cold water into a jelly, possessing all the properties of gelatine; to which we must add gluten, the animal portion contained in the husk, from which the finest flour is not wholly free, but which in the coarser kind is copious. The gelatine, therefore, gives bread its most striking characteristics, and we find them in the ship biscuit, which consists of flour and water only, and is a tough, hard, insoluble substance. These inconveniences are avoided by yeast or leaven, which, in the common bread, gives a lightness, as well as a greater degree of solubility to the mass. The changes produced by the leaven have been variously explained. They have been attributed to fermentation; but this has been denied, because in no part of the process do we find an ardent spirit. We may take, however, this opportunity of remarking, that our not discovering either of the products of fermentation is no proof against its existence. We scarcely, in any instance, see an ardent spirit produced in the process of digestion; yet in this, fermentation certainly takes place, with its usual attendant, assimilation. In ricks of hay we find no ardent spirit at any period, but it certainly has existed; since, when too damp, ricks will inflame, and when hay is in its best state, we find an evident smell of acetous æther, which shows that a spirit has been formed. The ancient leaven proves, that this process was not very different from fermentation: it was the remains of former bread in a sour state. The modern leaven, the yeast or barm, is a farinaceous solution in a fermenting state, abounding with carbonic acid gas, copiously evolving, in fact, the vegetable acid in the form of air, with an excess of oxygen, which must have a similar effect. It is, however, more rapid in its operation, produces the change much sooner, and, as it is also more quickly checked by the heat of the oven, does not, like leaven, occasion the sour taste in the bread. The use of leaven is of considerable antiquity, for it was known beyond the era of our most ancient and sacred records. The substitution of yeast is of a comparatively late date. The art of making bread was brought to Rome from Macedonia about the year 580, from the building of the city. Before that time the corn was mixed with boiling water, probably like the oatmeal in the neighbouring kingdom of Scotland. Such at least is Pliny's account. The other component parts of flour vary in some measure the properties of the

bread. Thus, from the mucilaginous and saccharine portion, it is liable to become sour, and from the gluten, musty. The former is the more common fault of the finer bread, and the latter of the coarser. The latter also is more difficult of digestion, and fit only for the stronger stomachs, which are better able to resist the putrefactive tendency. The use of salt in bread is not easily explained. It may be supposed to act as a condiment were it in a larger proportion, but it is generally said to promote union of the meal and water.

From this view of the subject, we shall be able to understand the difference between the household bread and the ship biscuit. The latter is not leavened, and consequently not so readily acescent; but it is harder of digestion, and, alone, not adapted to weak stomachs. For these it must be comminuted so as to form a pulp, and warmed by some carminative seeds, or united with animal food; when its undigestible nature contributes to retard the aliment, and render its assimilation more perfect. This doctrine will be elucidated under the article of CONDIMENTS.

Various are the forms of bread, and numerous the additions to adapt it to the taste of the luxurious. Every saccharine substance renders it more acescent, every farinaceous nut more difficult of digestion. The carminative seeds, of which the principal is the carui, or, on some occasions, as in the gingerbread, the aniseed, lessen the inconvenience, but render it less suitable for a common aliment. The drier the bread, the less ready is it to become acescent: hence, new bread is often inconvenient in the stomach; and rusks, which consist of bread sliced and again baked, are scarcely less useful than sea biscuits.

Various adulterations of bread may be mentioned. Among the rest, bone ashes and bean flour are the principal, and chiefly used to whiten bread which has an over proportion of bran. Alum, too, has been employed, but its operation we do not well understand. It is said to coagulate the gelatine; and perhaps may be useful when it contains too large a proportion of humidity, or, in the language of bakers, when the corn is melted. Potatoe bread, or at least the method of making bread with a proportion of these roots, is an art sufficiently known. Bread of this kind is white, light, and wholesome: it keeps without injury for many days.

Turnip bread is made from the expressed mash of boiled turnips with an equal weight of meal; while the farina of potatoes may be made into bread with any proportion of meal, or even alone. The turnip bread has at first a slight taste of the root, which goes off in a few days, and it is then said to be even superior to that made with flour.

In a medical view, bread has been tortured to obtain its nutritious qualities in a liquid form. The chief form of this kind is the bread jelly, viz. bread boiled till the water has extracted a sufficient portion of the gelatine to become a jelly when cold. Bread also is often boiled with broth, when the patient can swallow nothing solid. In each form it is apparently useful. A brown toast infused in water gives it no unpleasant flavour, and it sits more easily on the stomach than water alone. When fresh, and sipped only in small quantities, it often relieves vomiting; and as a common drink in fevers, is peculiarly grateful and advantageous. Bread

distilled produces an highly acrimonious empyreumatic oil, mixed with an acid. Yet, in Germany, a simple water distilled from it, previously adding the juice of cray fish, rose water, nutmegs, and saffron, is used as a restorative nutriment. From nutmegs, cinnamon, bread, and rhenish, a spirituous water is produced, supposed to be useful in diseases of the stomach. Hoffman recommends a spirit from bread distilled in the dry way. When the oil is separated, he thinks it a good sudorific.

BREAST. In general means the chest. For its most important organ see MAMMA.

BREATH. The air expired. In many persons it is fetid. This is sometimes constitutional, but more often the effects of rotten teeth, inattention to cleanliness, or sometimes the sign of approaching fever.

BREE'DING. See PREGNANCY.

BRE'GMA, (from *βρεχω*, to moisten). In infants these bones are not only tender, but very moist; and sometimes so in adults. They are also called *sinciput*, *parietaria*, and *medium testæ*. They are two bones on the upper part of the head, of an irregular square figure, nearly of the same thickness all over, and divided into an upper and lower part by a circular line; on the upper part they are covered only by the integuments, on the lower by the crotaphite muscle; towards the posterior and upper part, there is a hole through which the vessels of the dura mater communicate with those of the scalp. These bones have a large extent, but are the weakest in the human body. The trepan may be applied to any part of this bone, except on the lateral parts of the posterior lower edge of it, the lateral sinuses lying under them. It often happens that tumours are formed on these bones in infants, which contain a fluid, and conceal the osseous substance. These tumours should be left to nature, and their contents will be taken up by the absorbent system.

BRE'LISIS. See CARANNA.

BRETA'NICA. It is said to be a Frieslandic word, and means that it should be put between the teeth to cure the hiccough; *Bret tand hic*. GREAT WATER DOCK. See BARDANA MAJOR.

BRE'VIA VA'SA, (from being short). The vena splenica towards its termination is divided into several branches that go to the spleen, one of which produces the veins which receive this name.

BRE'VIS, vel BRA'CHYS. A name of the TERES MINOR.

BREYN. CENT. An abbreviation of Jacobi Breynii, *Exoticarum aliarumque minus cognitarum Plantarum Centuria prima*. Gedani, 1678.

BREYN. HIST. COCC. An abbreviation of J. P. Breynii *Historia Naturalis Cocci Radicum Tictorii*. Gedani, 1731.

BREYN. PROD. An abbreviation of Jacobi Breynii, *Prodromus, Fasciculi Rarior. Plant.*

BREYN. SCHED. An abbreviation of Jacobi Breynii *Schediasma de Echinis*.

BRICUMUM. See ARTEMISIA.

BRINDO'NES. (Indian). A fruit in the East Indies. Vinegar is made from it, and it is also a material used for colouring; reddish on the outside, and of a blood red within. The MANGOUSTAN of the Celebes. q. v. Raii Hist.

BRINE. The fluid which is separated from meat that has been salted, containing a solution of the salt.

with albuminous and other animal fluids. It is used, externally, as a stimulant in palsies, and œdematous swellings of the legs; and is sometimes poured with advantage into the ear when filled with viscid cerumen, or, when the action of the ceruminous glands is too languid.

**BRISTOLIE'NSIS A'QUA.** **BRISTOL WATER.** Of the four principal warm waters naturally produced in England, this is of the lowest temperature. See **BATHONIENSIS AQUA**.

As the Bath waters are proper where the secretions are defective, so the *Bristol water* is of service when in excess. The Bath water warms; the *Bristol* cools. Bath water relieves the stomach and intestines; the *Bristol* the lungs, kidneys, and bladder. It issues from a limestone rock.

By the experiments of Dr. Bryan Higgins, a Winchester gallon of this water contains,

	dwts.	gr.
Of calcareous earth, combined with vitriolic acid in the form of sclenite	-	0 8½
Of calcareous earth, combined with acidulous gas	-	0 12¾
Of marine salt of magnesia	-	0 5¼
Of sea salt	-	0 6½

Acidulous gas, besides what is contained in the calcareous earth above mentioned, eight ounce measures. Dr. Carrick found a little difference in the proportions, and adds to the ingredients sulphat of soda.

Little can be therefore expected from the mineral contents of this water. It has, however, been supposed useful in internal hæmorrhages, immoderate discharge of the menses, old diarrhœas, fluor albus, internal inflammations, spitting of blood, dysentery, purulent ulcers of the viscera, consumption, dropsy, scurvy with heat, stone, gravel, strangury, habitual gout, atrophy, slow fever, scrofula, gleets, and a diabetes; in which last it is esteemed a specific, and is allowed to be drunk as freely as the thirst requires it. The sensible qualities of this water render any particular directions for its use ridiculous.

The hotter months are the best for using it. In general it is drunk in repeated draughts of half a pint, from a pint to two quarts a day.

The *Bristol* and *Matlock waters* are of exactly the same qualities.

See Dr. Maplet, Dr. Guidot, and Dr. Wynter, on the *Bristol Waters*. It was Doctors Mead and Lane who established the reputation of *Bristol water* in diseases of the kidneys and bladder. The latest author on this subject is Dr. Carrick.

**BRITA'NICA.** The herb called *britannica* has occasioned numerous discussions, and it was supposed singular that it should not be known in Britain. The mistake respecting the meaning of the term occasioned the difficulty. (See **BRETANICA**). It seems to have been the *rumex aquaticus* Lin. Sp. Pl. 479, from the descriptions of Pliny and Muntingius. See **BARDANA**, and **LAPATHUM AQUATICUM**.

**BRITTLENESS.** See **FRAGILITAS**.

**BRI'ZA**, (from *βριζω*, to lull to sleep; because bread made of it causes drowsiness). **SPELT WHEAT**.

**BRO'CHOS.** Castellus thinks it must mean some chirurgical instrument, inasmuch as it is necessary to some operations, on the authority of Galen and Oribasius. It is considered also as expressive of some

diseases, particularly, according to Galen, of a deprivation of voice. Indeed, in surgery it is a noose, and belongs to either instruments or bandages, for it is the Greek word for *laqueus*.

**BRO'CHTHUS.** The THROAT, (from *βρεχω*, to pour). See **GUTTUR**. Also a small kind of drinking vessel.

**BRO'CHUS.** One with a prominent upper lip, or one with a full mouth and prominent teeth.

**BRO'DIUM.** **BROTH.** (See **JUS**). It sometimes means the liquor in which a solid medicine is preserved, or with which it is diluted.

**BRO'MA.** **FOOD**, (from *βρωστω*, to eat,) in opposition to drink. See **ALIMENT**.

**BROM. CHLOR. GOTH.** An abbreviation of *Olai Bromelii Chloris Gothica*, seu Catalogus Stirpium circa Gothoburgum nascentium.

**BROME'LIA.** See **ANANAS**.

**BRO'MION**, (from *βρομος*, the oat). A plaster mentioned by P. Ægineta: and so called because it was made of oaten flour.

**BRO'MUS STE'RILIS**, (from *βρωστω*, to eat). **DANK OF WILD OATS.** See **ÆGYLOPS**.

**BRO'NCHIA**, (from *βρογχος*, the throat). See **ASPERSA ARTERIA**, and **BRONCHUS**.

**BRONCHIA'LES ARTE'RIÆ.** They sometimes go from the fore side of the superior descending aorta, at others from the first intercostal, or from the arteriæ œsophageæ. Occasionally they arise separately from each side to reach each lobe of the lungs, and sometimes by a small common trunk, which afterward separates towards the right and left hand, at the bifurcation of the aspera arteria, and the branches accompany the ramifications of the *bronchiæ*.

The *bronchial* artery on the left side often comes from the aorta, while the other arises from the superior intercostal on the same side; which variety is owing to the situation of the aorta. Sometimes there is another *bronchial* artery, which goes out from the aorta posteriorly, near the superior intercostal, above the *bronchialis* anterior.

Communications have been observed between the *bronchial* artery and the vena azygos, and with the coronary artery of the heart. Ruysch first discovered these vessels, and he describes both the *bronchial* arteries and veins in his fourth epistle.

**BRONCHIA'LES GLA'NDULÆ.** At the angle of the first ramification of the trachea arteria, we find on both the fore and back parts certain soft roundish glandular bodies of a bluish or blackish colour, and of a texture partly like that of the thymus, and partly like that of the thyroid gland. There are many similar glands at the origin of each ramification of the *bronchia*. Dr. Hunter supposes their office is to separate a mucus to lubricate the lungs: they are different both in colour and structure from the conglobate and lymphatic glands.

**BRONCHI'ALIS GLA'NDULA.** See **THYROIDÆA GLANDULA**.

**BRONCHOCE'LE**, (from *βρογχος*, the wind pipe, and *κηλη*, tumour). Also called *bocium*, *botium*. It hath various names in different writings; the Swiss call it *gotre*; some have called it *hernia gutturis*, *gutter*, *tumidum*, *et trachelophyma*, *gossium*, *excehebronchos*; *gongrona*, *hernia bronchialis*: Heister thought it should be named *tracheocele*. Mr. Prosser, in his late publication

on this disorder, from its frequency on the hilly parts of Derbyshire, calls it, with others, the DERBYSHIRE NECK; and, not satisfied respecting the similitude of this tumour with that observed on the neck of women on the Alps, the English *bronchocele*. As various causes give rise to this complaint, he endeavours more strictly to distinguish that in which he expects success in his attempt to cure. When not produced by accidents, such as loud speaking, crying, blows, he calls it the natural, the spontaneous, or the curable *bronchocele*.

The seat of this disease is the thyroid gland, which Dr. Hunter hath observed lies just below the larynx, round the trachea. The tumour appears in the fore part of the neck, between the skin and the wind pipe. Women are the most frequent subjects of it, and in them it usually appears early. Dr. Hunter met with one case of this kind in a young surgeon; but it rarely happens in males.

Various causes are assigned by different writers. On the mountainous parts of Genoa and Piedmont, they attribute these tumours to drinking water cooled with ice. Dr. Leake thinks it very probable that such glandular swellings as happen about the neck and face, may be owing to the severity of the cold moist air, especially since they generally appear in winter, and rarely in the warm dry climates of Italy and Portugal. This, he adds, is probable, because the intense degree of cold may constrict the glandular ducts, and lock up that fluid which ought to pass freely through them. Some writers attribute it to a scrofulous cause. Mr. Prosser inclines to think that it is a dropsy in the gland, and similar to the dropsy in the ovaries. He relates, that Dr. Hunter dissected one of these glands that had been considerably enlarged, and it was found to be distended by a number of cysts filled with water, which must have been hydatids. Yet most writers agree that its true cause and nature are alike unknown.

The *bronchocele*, Mr. Prosser observes, is a tumour arising on the fore part of the neck; it generally first appears some time betwixt the age of eight and twelve years, and continues gradually to increase for three, four, or five years; and sometimes the last half year, we are told, it grows more than for a year or two before. It generally occupies all the front of the neck, for the whole thyroid gland is enlarged; but it does not rise near so high as the ears, as in the cases mentioned by Wiseman; and it is rather in a pendulous form, not unlike, as Albucasis says, the flap or dewlap of a turkey cock, the bottom being the larger part of the tumour. In figure, it varies considerably in different cases. It is soft, or rather flabby to the touch, and somewhat moveable; but, when it has continued some years after it has ceased to increase, it becomes more firm or confined. By the situation and nature of the complaint, it generally occasions a difficulty of breathing, which is increased on the patient's taking cold, or attempting to run. In some the tumour is so large, and so much affects the breathing, as to occasion a loud wheezing; but we meet with many exceptions to this general rule. When large, patients sometimes suffer but little; others suffer much from an inconsiderable tumour. In general, however, it occasions little inconvenience. Dr. Hunter observed, that this tumour now and then suppurates.

The *bronchocele* should be distinguished from a

scirrhus, from an aneurism, and from those swellings in the neck that arise from strains or ruptured vessels. The distinction, however, is not difficult.

This tumour never becomes cancerous. Mr. Gooch says, he never knew this tumour, however large, to endanger life; but he observes a considerable inconvenience from it in cases of quinsy combined with it. Mr. Sharpe mentions, that the only cases of quinsy requiring bronchotomy, were owing to the presence of bronchoceles. Dr. Hunter has observed, that this disorder appears two or three years before or after menstruating; and that it sometimes spontaneously disappears, if the menstruation approaches kindly. Mr. Prosser thinks that this change in the constitution scarcely ever affects the tumour. We have never found that it has produced any diminution of its bulk.

The drain of an issue, or of a perpetual blister, applied on some other occasions, has apparently prevented the growth of the bronchocele, though the effect continued only during the drain. It cannot be extirpated, as it is entangled with the recurrent nerves, and the first branch of the external carotid artery; and if by chance a suppuration is formed, an ill conditioned ulcer, difficultly cured, is the consequence. Mr. Prosser hath succeeded, in many instances, in discussing it. On this plan, the late famous Coventry practice was formed, which Mr. Wilmer has inserted in an Appendix to his Cases in Surgery. It begins with an emetic the day after the moon is at the full, and, the day after that, a purge is given; the night following, and seven nights successively, the following bolus is laid under the tongue at bed time; and, in the days, a bitter stomachic powder given at noon. On the eighth day the purge is to be repeated; and, in the wane of the succeeding moon, the whole process to be repeated, except the emetic. The tartar emetic ointment rubbed in on the tumour is supposed to assist the cure; and, indeed, by adding this application to the Coventry receipt, we have often succeeded in greatly reducing bronchocele. Mr. King gives the burnt sponge in the dose of a scruple three times a day; but, if his recipe be correct, two ounces of the sponge in twenty-four troches must amount to two scruples in each. He attributes the cure to the quantity, which, we think, with many stomachs would be inconvenient. THE LOZENGE TO BE LAID UNDER THE TONGUE is formed of *calcined sponge, cork, and pumice stone*, of each ten grains, *syrup* a sufficient quantity.

Mr. Prosser has succeeded by the use of his medicines, though the patient was nearly advanced to her twenty-fifth year, more than twelve years after the appearance of the tumour on the neck: after the twenty-fifth year, no instance of success hath occurred. He orders one of the following powders to be taken early in the morning, an hour or two before breakfast, and at five or six o'clock in the evening, every day for a fortnight or three weeks. The powder may be taken in a little syrup, or sugar and water, or any thing else, so that none may be lost. If it does not sit well on an empty stomach, it may be taken betwixt breakfast and dinner.

R. Cinnab. ant. op. levigat. milleped. ppt. et pulv. aa gr. xv. Spong. calcinat. ʒ i. m.

These powders should be taken for two or three weeks, then omitted for about a week or nine days; the same course must be then repeated. At bed time every

night, during the second course of the powders, three of the following pills are to be taken :

R. Hydrargyr. ʒ v. terebinthinæ Strasburgensis ʒ ij. extracti colocynthidis comp. ʒ iv. pulv. rhabarbari ʒ i.

First grind the quicksilver with the turpentine till it appears no longer, then add the rest, and form a mass. If the turpentine be too thick, a little olive oil must be added.

These medicines do not require confinement, except they are taken in severe weather, and then only to the house; nor need the diet be much regarded. It may be sufficient that the medicines are taken in a temperate season, or rather warm weather, and the patient lives exactly in the usual way, guarding against cold during the second course of the medicines. The patient, if a servant, should avoid standing, especially at the washing tub, or any work with cold water. As to diet, when no alteration hath been made in it, the success has been the same as when stated regulations were regarded. In this discretion may occasionally direct. If the pills continue to purge, after taking them a few days, it would be better to leave out the extr. coloc. comp. in their preparation, and lessen the dose in the same proportion. In general it will be proper for the patient to be purged twice or thrice with manna and salts, or any gentle cathartic, before the powders are begun. The medicines are here proportioned for an adult of a good constitution; therefore, if the patient is younger, or of a weakly habit, the doses must be managed accordingly. As to external applications, they may be hurtful, but do not appear likely to be useful.

The patient must not expect to find benefit in a little time; perhaps it will be as long after the medicines are all taken, as the time they are in taking, before much difference will be perceived in the tumour of the neck. It is necessary that the medicines be begun at a proper time, especially the second course; a few days should always be dispensed with on that account.

Amongst the earlier writers, Albucasis is the first who gives any useful account of this disorder. See it translated into Friend's Hist. of Physic, and into James's Med. Dict. art. Bronchocele. See also Turner's Surgery, vol. i. p. 164. Wilmer's Cases and Remarks in Surgery, in the Appendix. An Account of the Method of Cure of the Bronchocele, by Thomas Prosser, edit. 3. Gooch, in his Med. Obs. gives an instance of an aqueous bronchocele. Bell's Surgery, vol. v. 514. White's Surgery, 289. Memoirs of the Medical Society of London, 217.

BRO'NCHOS, (from βρογχος, *wind pipe*). A suppression of the voice from a catarrh. Also a catarrh, when it principally affects the fauces. See CATARRHUS.

BRONCHOTO'MIA, (from βρογχος, *the wind pipe*, and τέμνω, *to cut*). BRONCHOTOMY. See TRACHEOTOMIA.

BRONCHUS, (from βρεχω, *to pour*). The ancients believed that the fluids were conveyed by the bronchiæ; whence its name. According to Galen it is the *aspera arteria*, from the larynx to the lungs; but, bronchiæ or bronchi, as now understood, are the ramifications.

BRO'NTE, (quasi βροντη, from βρεχω, *to roar*). THUNDER. Was it from hence Lord Nelson derived his title?

BRU'MA. Some derive it from Βρῦμος, *Bacchus*, because at that time the feasts of Bacchus were cele-

brated: but, more probably, quasi *brevima*, for *brevissima dies*. WINTER. But particularly when the days are shortest.

BRU'MASAR. A spagirical term for silver. See ARGENTUM.

BRUNE'LLA. COMMON SELF HEAL; called also *prunella*, *consolida minor*, and *symphytum petraeum*. It is the *prunella vulgaris* Lin. Sp. Pl. 837. Nat. order *labiata*. It is perennial, grows wild in pasture grounds, and flowers in June and July. In taste it is slightly austere and bitter, and much used in fluxes, hæmorrhages, and in gargarisms, as well as to remove aphthous exudations in the mouth. Miller's Bot. Off.

BRUNNIE'RI GLANDU'LE. BRUNNIER'S GLANDS. So called in honour of their discoverer. They are lodged under the villous coat of the intestines, closely adjoining to the nervous; and are smaller than in the large ones. They are also called *Peyer's glandule*, PEYER'S GLANDS.

BRUNONIAN SYSTEM. We have already explained our reasons for adopting the plan of giving distinct views of the most prevailing medical systems in different articles (see BOERHAAVIAN SYSTEM), and shall pursue the present meteor from its first spark to its meridian: others may perhaps record its decline or fall. The history of Dr. Brown would not be of importance in this place, were it not necessary to explain some parts of his doctrines. Originally a teacher of Latin, he attended the medical classes by the permission of the different professors; and, as the tutor of his sons in that language, was first connected with Dr. Cullen, to whom he became an useful assistant, and of whose doctrine he was a warm admirer. His great object for a future maintenance when we knew him, was to repeat Dr. Cullen's lectures in London after his death. Some disagreement turned him to a virulent antagonist, and from hence arose the BRUNONIAN DOCTRINE.

We mean not by this to prejudice or disparage the system: it must rest on its own merits: but, to explain that decided opposition, and the virulent language employed when speaking of the Cullenian doctrines. We suspect, however, that it may explain the source of some of his own opinions, without giving him the credit of a very brilliant genius; for, in possession of a system with the arguments in its support, it is not very difficult to say that any part is '*false*,' and to wrest the arguments to the opposite opinion. If, however, his system be well founded, it proves his genius to be pre-eminent, for little was gained by study. We recollect but one author quoted, which is Triller; and, from the manner of the quotation, we should suspect that he was not intimately acquainted with him. The opinions and practice of different authors he could not have been ignorant of, from the lectures he attended; yet it is singular that his practice is so little discriminated, that he seems scarcely to have visited the sick bed, or attended to the distinguishing symptoms which influence the practical physician in the minuter variations of his conduct.

Dr. Brown, however, started as a self appointed lecturer, and the avowed opponent of the Cullenian system. His doctrine, even more simple than that of the methodists, admitted only of the strictum and laxum, the sthenic and asthenic states, without allowing the union of both. Simplicity is attractive to youth; it is

falsely called 'the seal of truth;' and to escape from professorial dogmas, added to the seduction. It is at least certain, that after some months of hesitation Dr. Brown was greatly followed, and his doctrines were echoed in the "Medical Society," where the Cullenian system had gained a complete victory over the Boerhaavian; and, by the aid of the numerous pupils of that school, was disseminated through Europe, Asia, and America. It was eagerly caught at on all sides; but, by a strange perversion, in escaping from the humoral pathology, many professed Brunonians adopted doctrines essentially distinct from those of Brown, supposing that if they were not Boerhaavians, they were of his sect.

Dr. Brown seemed to consider man, not as a being compounded of an organised system to which the principle of life was superadded, but as a machine, to which a certain series of actions and effects is allotted by means of an excitability, differing in degree, but generally, though on the whole imperceptibly exhausting. In fact, it is a flame kept alive by excitements, such as heat, food, passions, &c. which, however, destroy by degrees the pabulum, or, in his language, the excitability. As the machine is merely passive, and the flame kept up by blowing, it cannot be depressed except by an intermission of the blast. It may, however, be exhausted by blowing too violently; or the pabulum, not exhausted by the constant blast, may burn with greater fury on its recommencement. We mean merely to facilitate the reader's conception by our metaphor, not to render the subject ludicrous.

Life, therefore, is a 'forced state;' every thing stimulates; some substances too violently, others not sufficiently: and we thus have two kinds of debility, indirect and direct. In the former case, the strongest stimuli are necessary; in the second, the slightest destroy in consequence of too great irritability. In the gaol fever, for instance, we must give the strongest stimulants: to the man long pent up in darkness, with scanty food, the light must be moderate, the aliment of the mildest kind, and stimuli of every sort most sparingly administered; as the flame, long repressed, would be roused by the slightest excitement.

Such is the basis of Dr. Brown's system; and for one part of it, accumulated excitability, he deserves the greatest credit. It is a law of the animal economy so general, that the attention to it directs the practitioner in various ways; nor should he, on any occasion, lose sight of its consequence, that too frequent and violent excitements are destructive. It had been well if Dr. Brown had kept it more often in view, particularly in his arrangement of diseases. There is, however, another law of the system connected with this, which has been less adverted to, viz. that excitability, long repressed, is with difficulty, if at all, to be roused by stimulants. Constitutions of this kind are ruined from inactivity; they rust, as we have said, on their hinges; and the Brunonian will not refuse this addition to his system, since it is so connected with his principle, that life is a forced state.

This principle, however, we cannot admit. Life is superadded to organized matter; for organization itself will no more produce it, than the most skilful union of wheels will produce a time piece without its spring. This leads to a fundamental objection to the Brunonian system; that, by giving man in the beginning a de-

termined proportion of excitability, he has no where provided for its renewal, when exhausted. It accumulates from want of exhaustion, but from what source? For, let only an atom be taken from a mountain, and in no way restored, the mountain must in that proportion be diminished, and cannot regain its former bulk. Boerhaave and Cullen felt the difficulty. Boerhaave supplied it by secretion; Cullen, more indistinctly, made it the consequence of collapse, alluding by some remote analogy to the electrical fluid. Brown cut the knot, and, like Jack in the tale, would be 'as unlike the rogue Peter as possible;' *so that there must be no collapse*. Brown himself speaks of 'recruiting the excitability; and his followers, when urged by the difficulty, have either evaded it, or explained in a way not very consistent with the general principle.

Again: Dr. Brown speaks of indirect and direct debility, of the two states of exhausted and accumulated irritability. The gaol fever is allowed to be an instance of the former, and the person, secluded from light and air, of the latter. Yet, did Dr. Brown never see (we believe he never did) in the gaol fever, inordinate stimuli fatal by their excess? Did he never see phlegmonic inflammation sometimes supervene? To the angina maligna, too, a very similar disease, the inflammatory angina sometimes succeeds from too violent and long continued stimuli. How, however, in the gaol fever, one of his own instances, is the excitability exhausted by excess of stimuli? Every previous cause, every concomitant circumstance, has a tendency totally different. In this and the other instance of indirect debility, we see only the powers of life gradually exhausting, in a certain degree to be roused with augmented violence by stimuli; but, after a certain period, incapable of any excitement: while even the effects of stimuli, though apparently for a time successful, often contribute to destroy the remaining portion of excitability. The difference of the two cases consists in this only, that the excitability in the latter is only accumulated; but in the former, by the debilitating power of the fever, added to that from the confinement, in a great measure destroyed, or at least so far diminished as to be very generally irrecoverable.

A striking instance of accumulated excitability occurred in that singularly intrepid exertion of captain Bligh, when he crossed the Pacific in a small boat, with a very inconsiderable stock of provisions. On reaching Timor, one of his crew died of an inflammatory fever. Had these men after their voyage been thrown into a loathsome prison, or an infected hospital, would they have escaped? We know they would not, for similar instances have occurred; yet in these we might in vain look for the stimuli by which the excitability had been exhausted.

A consequence of this doctrine must be, that every medicine stimulates; and the difference between what are styled stimulants and sedatives is, that the latter are not sufficiently stimulating. This, however, must soon become a verbal controversy. The oxygen of the atmosphere stimulates the lungs, and hence the whole system; but if the oxygen is deficient, the stimulus is abstracted, and the machine no longer urged on. Yet this is not the only stimulus; if we abstract oxygen, we may supply an additional stimulus by warmth: abstract warmth, also, and the passions may supply its

place. Without all these exciting powers, we need not despair; we have brandy, laudanum, and æther. It is sufficient to state this reasoning, which, on Brunonian principles, is fair, to show its fallacy. Azote and hydrocarbonate, when breathed without dilution, immediately kill. Is this from deficient or excessive stimulus? If from the former, it differs in no degree from a sedative: if from excessive stimulus exhausting excitability, we can only say that the existence of the previous stimulus is gratuitous; and we have long since learnt, that, *quod verbo dicitur, verbo negare sat est*. If no stimulus appears, we cannot place sufficient confidence in any assertion to believe that it exists.

But these are harmless speculations. When we find them applied to practice, humanity shudders at the dangerous tendency of many of these doctrines. If we can trust reports, their application has been very extensively injurious. As the trammels of a system are every where conspicuous, so diseases are supposed to be either sthenic or asthenic. Those arranged under the former class are, *peripneumonia, phrenitis, variola, rubcola, erysipelas, rheumatism, cynanche tonsillaris, catarrhus, synocha, scarlatina, mania, fervigilium, and obesitas*. The asthenic diseases are, *macies, inquietudo, eruptio scabiosa, diabetes lenior, rachitis, menstruorum cessatio suppressio et retentio, mænorrhæa, epistaxis, hæmorrhoids, sitis vomitus et indigestio cum affinibus alimentarii canalibus morbis, pueriles affectus scil. vermes et tabes, dysenteria et cholera, scorbutus, hysteria levior, rheumatism, tussis asthenica, pertussis, cystirrhæa, podagra validiorum et imbeciliorum, asthma, spasma, anasarca, colicodynia, dyspepsodynia, hysteria gravior, hypochondriasis, hydroph, epilepsia, paralysis, apoplexia, trismus, tetanus, intermittentes, dysenteria et colica gravior, synochus, typhus simplex, cynanche gangrenosa, variola confluenta, typhus, pestilens et pestis*. The local diseases follow, among which we see with some surprise, the internal inflammations of the abdomen, abortion, and difficult births. Deep wounds, suppuration, pustula, anthrax, bubo, gangrene, sphacelus, scrofulous tumours, and scirrhus, may with more propriety be considered as local diseases, yet these often require general methods of treatment.

The cure is as simple as the arrangement. Bleeding, low diet, and purging, cure the sthenic diseases; stimuli, of different kinds and degrees, the asthenic. Is it surprising then that this system should have its admirers? The labour of study is at once abridged. The works of Galen and his followers may be again burnt in solemn state; and the degree of strength or debility registered on a scale, may be at once attacked by the appropriate weapon. Sad is the history which must follow. The victims of the yellow fever in the West Indies were often laid low after full doses of Madeira, bark, and laudanum. We have seen the hectics raised into a destructive flame by similar means; and the typhus fever aggravated by equally undistinguishing management.

We cannot pursue the list minutely, but shall take an instance or two from each class. Peripneumony is a sthenic disease, and is attacked, as usual, by bleeding and purging. If this plan be followed, the fever is mitigated, but the affection of the breast remains the same. For this, the only salutary discharge is the expectoration, which should be conducted with care. Of this discharge Dr. Brown takes no notice; and, unfortunately,

active purging will not only supersede, but prevent it: and we have no hesitation in saying, that few patients treated in this way would survive. We might notice also scarlatina and erysipelas. Either, treated by active bleeding and purging, would soon prove fatal. The treatment proposed for the latter may succeed in Scotland, but in this metropolis would at once sink the patient irrecoverably. Once more: obesity is a disease to be cured by bleeding and purging. In fact, there is no state of the system in which these evacuations are borne with so little advantage. The truly inflammatory habit is the strong, thin, firm, muscular highlander, or the English mountaineer. The opposite state is the irritable, hysteric female, generally plump, but weak, and soon sunk by discharges.

In the second class we see the asthenic cough, by which Dr. Brown means consumption; and apoplexy. In each case we must use active stimulants. In the latter we have said they must soon be employed, but not without previously lessening the quantity of fluids in the head, clearing the bowels with the most active laxatives, and establishing some drain to prevent the secondary accumulation. Of these precautions not a word is said, and without them the physician will not be very successful. We know this, for we have witnessed the events, and we alluded to them in the article of APOPLEXY, when we spoke of the accumulation of stimulants, till it was uncertain to what the relief, or more often, the failure was owing.

Of the fatal consequence of the stimulating plan in consumption, we have unfortunately had too many instances. With the best management the picture is gloomy; with the methods proposed it is deeply darkened. If there is any more striking feature than another in this complaint, it is increased irritability of the arterial system, and a larger proportion of oxygen in the fluids, with its accompanying irritation. Every meal of an animal nature increases the heat, the smallest quantity of wine or spirits raises it to a greater degree; and when again cooled, the patient sinks with languor and debility. Yet this is the disease treated with all the warmth of Brunonian stimulus! We are free to own that the lowering system has been carried too far; and that while we were guarding against fever, we neglected properly supporting the strength. The whole subject we shall have occasion to state at length, with the necessary distinctions; but the plan sanctioned by experience will be found far, very far distant from the practice recommended by Dr. Brown. Nor is the change in the plan to be attributed to him. It was suggested by experience, before the splendor of his coruscations had reached this country.

Of the gout we shall not again speak. Undoubtedly the system may be brought too low; and Dr. Brown, we suspect, would raise his arthritics too high. He himself suffered severely when he changed his free plan of living to a more abstemious one; but his case is not to be brought as an example, till his plan and its long continuance are more particularly known. We knew it; and in these more rational days, till we find similar plans have been adopted by our patients, we shall not recommend those in the work now before us, his own Latin edition, published in 1784.

Scurvy also is to be treated by stimulants; and these without the usual remedies, it is said by this author,

will succeed. Uniform experience has decided differently; and lemon juice *without* stimulants is, even at sea, found to be an effectual remedy. In the hooping cough, stimulants are also essential in Dr. Brown's opinion. Change of air is nonsense (*fabula*), and vomiting, death. It is somewhat surprising, that, in opposition to this dogma, hooping cough is seldom fatal, though these useless or dangerous remedies are employed, and with those recommended—but we have not heard of any one who has so far sinned against common sense as to employ them.

We have enlarged on this system and its application, because, as we have said, it is seductive from its simplicity, and the little labour required either in its study or its management. We have not dwelt on the minute investigation really required to adapt the stimulus to the state of direct or indirect debility in a given case; for, though we know that every disease varies in this respect, yet no provision is made for it in the system: the name and the class are only necessary. We observe, indeed, that Dr. Brown, in one or two instances, orders the stimulus to be somewhat less than that of the disease; but he no where points out the symptoms which discriminate its degree.

It is not wholly the neglect of distinguishing the degree of debility, either indirect or direct, and, of course, the proportion of stimulus to be employed, that renders the application of this system difficult or dangerous, but the very imperfect distinction of diseases. The descriptions are often the most meagre and imperfect; the diagnosis is seldom attended to. These, in fact, would require what the author never possessed, practical knowledge. The distinction also of different circumstances of a disease, which would require very different and often opposite treatment, is neglected; and when we find in the same class, to be treated with the same remedies, *menstruorum*, *suppressio*, and *mænorrhæa*, we shall begin to suspect that an attachment to system has precluded the observation of the operations of nature. When we see in the opposite classes, *pervigilium* and *inquietudo*, *phrenitis* and *epistaxis*, *colica gravior* and *enteritis*; in the same chapter the *podagra imbeciliorum* and *validiorum*, treated in the same manner, we cannot greatly rely on the judgment or practical knowledge of the author.

We had supposed the Brunonian system hastening to oblivion; but, in the last edition by Dr. William Cullen Brown, we are informed that it is generally adopted; and he asks triumphantly, what would have been the event had this system been promulgated from a professorial chair? Perhaps the delusion might have lasted longer, but the pupil will at last become a practitioner, and will bring his master's doctrine to the test of experience, nor any longer foster it than he finds it successful. His son speaks of the numerous converts to this new doctrine; but we have found few who, though they profess themselves the disciples of Brown, follow implicitly his system; and we have had numerous opportunities of remarking, that those who, on leaving the banners of Boerhaave, have adopted the nervous pathology, are rather Cullenians than Brunonians. Dr. Darwin, it is said, was a Brunonian before Brown was known: in reality, his language is in some parts nearly the same, but his practice, though peculiar, most remote; and, if the analogy is pushed further, the term

should at least be altered, and the system styled *Darwinian*.

BRU'NUS. See ERYSIPELAS.

BRU'SCUS. See RUSCUS.

BRU'TA. (Arabic). That virtue of the celestial influence manifested by the brutes, as in the stork teaching the use of salt in clysters.

BRU'TIA. An epithet for the most resinous kind of pitch, therefore used to make the *oleum pissinum*, said by Ray to be the same as the *pisselæon* of the ancients; for that was called by them *oleum picinum*; and was, according to Galen, a medicine made of oil and pitch. The pix *Brutia* was so called from *Brutia*, a country in the extreme parts of Italy, and made from the *tæda*, MOUNTAIN PINE.

BRUTI'NO. See TEREBINTHINA.

BRU'TOBON. The name of an ointment used by the Greeks.

BRUTU'A. See PAREIRA BRAVA.

BRUXANELI. (Indian). A tall tree in Malabar: its bark is diuretic. Raii Hist.

BRY'GMUS, (from *βρυχω*, to make a noise). A peculiar kind of noise, such as is made by the grating of the teeth, or their gnashing.

BRY'ON, (from *βρω*, to germinate). Called *splachnon* by some: a kind of moss found on cedars, oak, &c. It is astringent.

BRY'ON THALA'SSIUM. See ALGA.

BRYO'NIA, (from *βρω*, to abound). So called from its abundance. It is a name for the WHITE JALAP; also BRIONY.

BRYO'NIA A'LEA. WHITE BRIONY; called also *vitis alba*, vel *sylvestris*; *agrostis*, *amphelos*, *archeostriis*; *echetrosis*, by Hippocrates; *bryonia aspera*; *cedrostis*; *chelidonium*; *labrusca*; *melothrum*, *ophrostaphylon*; *psilothrum*; WILD VINE. This species is chiefly used. It is the *bryonia alba* Lin. Sp. Pl. 1438.

It is a perennial rough plant, grows wild in hedges, and climbs up bushes, with curled tendrils: the leaves are in shape somewhat like those of the vine.

These roots are taken up in spring, and afford a thin milky juice, which hath a disagreeable smell, and a nauseous, biting, bitter taste: if applied to the skin, it blisters. If the root be dried, or its milky juice inspissated, they lose most of their acrimony and nauseous smell.

Externally, this root is powerfully discutient. Dr. Alston observes, that in swellings, strains, and stiffness of the joints, he has experienced surprising effects from it; in contusions, a decoction of it with the addition of wormwood, does great service. According to Bergius, it is a *purgative*, *hydragogue*, *emmenagogue*, and *diuretic*; the fresh root emetic: it has chiefly been employed in *dropsies*, in *asthma*, *mania*, and *epilepsy*. In small doses it is said to be diuretic, resolvent, and deobstruent. In powder, from ʒ i. to a drachm it is strongly purgative. The juice, which issues spontaneously, in doses of ʒ ss. or more, has similar, though more gentle, effects; but the watery extract acts more mildly to the powder, and with greater safety. The dose ʒ ss. to ʒ i. Of the expressed juice, a spoonful acts violently both upwards and downwards; but cream of tartar is said to take off its virulence. As a discutient, the CATAPLASMA BRYO'NIÆ COMPOSITUM is much re-

commended. Of briony root three ounces, elder flowers one ounce, are boiled till they become tender; to which are added half an ounce of gum ammoniac dissolved in vinegar, muriated ammonia two drachms, camphorated spirit one ounce.

**BRYONIA NIGRA.** BLACK BRIONY; called also *tamus*, *sigillum beate Mariæ*, *chironia*, *afronia*, *gynecanthe*; BLACK VINE, and the CHIRONIAN VINE. This plant climbs without tendrils, the leaves are smooth, and, like those of the great bind weed, it bears black berries; the roots and leaves are commended as expectorant. Raii Hist. According to Gerrard it is called *agriampelos*, but is a variety of the *b. alba*.

**BRYONIA MECOACHANA NIGRA.** **BRYONIA PERUVIANA.** See JALAP and MECOACANA ALBA.

**BRYTHION.** (Greek). A malagina so called. It is described by P. Ægineta.

**BRYTIA**, (from *βρῦναι*, to devour). The solid parts of grapes which remain after the must is expressed.

**BRYTON.** *Βρυτον*, (from *βρῦναι*, to pour out). A kind of drink made of barley or rice, which Aristotle calls *pinon*. It is said that those who are drunk with it never fall but on their backs.

**BU'BALUS**, (dim. of *βας*, an ox). *Antilope bubalis* Lin. The BUFFALO; called *buffelus*, and *bos Indiana*. It is a kind of ox. This name it hath from the country in Asia from whence it was brought into Europe.

**BUBASTECORDIUM**, the HEART of BUBASTUS, (from *Bubastus*, and *cor*, heart). See ARTEMISIA.

**BU'BO.** A BUBO, (from *βουβων*, the groin). Vogel names it *bubon* when in the groin; it is also named *cambuca*, *cambuca membrata*, *codoccele*; by some it is called *fugile*, and *adin*. It is a tumid gland which is inflamed, or tends to suppuration: but it is generally understood only of those glands which are in the arm pits or the groin. Galen says, in his first book *De Diff. Febr.* 'a *bubo* is a kind of inflammation.'

Dr. Cullen ranks this genus of disease in the class *locales*, and order *tumores*. He defines it to be the suppurating tumour of a conglobate gland. See his *Nosology*, edit. 3.

Buboes are distinguished into MILD and MALIGNANT; the *mild* is that without manifest disease; the *malignant*, when excited by some pestilential or infectious disease, as the plague, or lues venerea.

The chief danger is from the bad habit of body, or some attendant disease: if neither of these accompanies the buboes, at the worst they are troublesome, painful, and tedious.

The cure of the mild kind will easily be effected by gentle mercurials externally applied, and occasionally a purge; though, if a suppuration threaten, it is best to encourage it, and proceed as in a common abscess.

A PESTILENTIAL BUBO is known by its appearing at the time of a pestilence, and being attended with its symptoms; though, indeed, the bubo is sometimes the first symptom. The appearance of a bubo, when the plague either prevails or attacks a person, is generally a happy presage, and in the management repellents must not be used, but suppuration encouraged; and as soon as a tumour appears, apply the speediest suppuratives, and second them by the use of cordial antiseptics inwardly. Its most common seat is the arm pit or groin. See PESTIS.

A VENEREAL BUBO very generally occurs in the groin, though, when the poison has been received in the hands or fingers, the arm pits are the seat; they tend very slowly to a suppuration, and are with difficulty healed when suppurated.

In the beginning, these tumours are sore if touched; hard, and gradually increasing, they become painful; if they tend to suppurate, an inflammation appears.

The distinction of bubo is of considerable importance. We shall not enlarge on pestilential buboes, only to urge the necessity of examining, during the prevalence of any epidemic highly asthenic fever, the groins and arm pits. The severity of the regulations in former eras respecting those affected with the plague, has led to the most dangerous concealments. We shall continue to speak exclusively of the venereal bubo.

Swellings in the groin may arise from hernia, from a retention of the testicle at the ring of the muscle, from a general scrofulous habit, or from poison absorbed from any part of the lower extremities. Those who are accurately acquainted with the situation of the lymphatic glands, which receive the absorbent vessels from the penis and from the lower extremities, for their situation is different, will not be easily deceived. It is not, however, usually suspected, that the latter are nearer to the root of the penis than the former. Those also well acquainted with the situation of the ring of the muscles, will not easily mistake a hernia for a bubo. But error is more easy in this, than in the former case. If therefore the tumour be hard, if it does not recede on lying back, if it has not receded in its earlier stages, if it does not force down on coughing or sneezing, and if the state of the bowels have not influenced it, the disease is either a bubo or a scrofulous swelling: the latter, however, is scarcely ever single. A chain of small obstructed glands occupies the groin, and the scrofulous diathesis is, in other respects, obvious. We omit mentioning the previous venereal complaints; for these are often industriously concealed, or it may happen that a bubo is the first symptom. The testicle, when detained, sticks at the ring of the muscle; but, were the situation not sufficient to discriminate the complaint, the want of one testicle would immediately lead to a suspicion and a full examination.

It has been usual to consider buboes as arising from irritation on the glans penis and mouths of the absorbents, or from the absorption of matter. The idea is consoling to the patient that the swelling is not venereal, but we fear it is fallacious. We know of no instance of irritation conveyed from the opening of a lymphatic to a gland, except by poison. No one will trust his health to this idea, and the distinction may be neglected. We know that some buboes yield easily, but we should not, on that account, be less apprehensive of lues following. A secondary bubo, viz. a deposition of venereal virus from the habit of the gland, has certainly no existence. The virus is directed to very different organs, and the opinion has been adopted in consequence of the deceit of patients, who are unwilling to confess the probability of a more recent infection.

It has occasioned some dispute, whether a bubo should be discussed, or brought to a suppuration. Two ideas have influenced either opinion; one, just noticed, respecting the source of the bubo from irritation; the

other, that the virus is there arrested, and if suppuration can be produced, may be evacuated without injury to the system. If, however, we examine injected lymphatics, we shall sometimes find, that of the numerous vessels directed towards a gland, some will not enter its substance, but pass over, or one side; nor can we be certain that, previous to the inflammation, some portion of the virus may not have been carried into the blood. To trust, therefore, to the opinion, that the poison can thus be arrested in its passage, is highly dangerous; and we lose a strong argument in favour of promoting suppuration. It is then reduced to a question of convenience; and there can be little doubt of the propriety of resolution, since in each view a mercurial course is indispensable.

To discuss buboes emetics have been employed. They undoubtedly promote absorption, but the most violent ones are requisite, and they are seldom necessary. Mercurial frictions on the part have been recommended, to extinguish, it is supposed, at once the peculiar virulence of the poison. In general, however, these from their irritation may produce inflammation; and, though for the ease of the patient's mind some part of the ointment should be rubbed on the bubo, the larger portion should be employed on the thigh, the groin, and perinæum. We reserve the discussion of the specific action of mercury at present. Cold applications freely employed have been useful; and the volatile liniment, rubbed *around* rather than *on* the tumour, has assisted the resolution. Leeches have been applied in the neighbourhood when inflammation has begun; and whatever plan be adopted, the patient should be kept on a low cooling diet and at rest, while frequent laxatives are interposed.

When we can thus succeed in discussing buboes, the remaining treatment will be that of syphilis. If, however, we fail, and suppuration is indispensable, we may be apprehensive of fatal effects from too great inflammation or irritation. In this case the most cooling medicines, with opium and bark, are necessary. In general, the irritation proceeds, *pari passu*, with the inflammation; and the cooling plan cannot be carried far, before the latter medicines are necessary. As the disease is before our eyes, we can distinguish the degree of inflammation, and be able to account for the symptoms we perceive. During the suppuration of a bubo, it is the most judicious practice to leave off mercury.

When, however, the suppuration proceeds tardily, a mercurial course will accelerate it; and in such circumstances, wine and other cordials are requisite. In these situations we can often discuss buboes, even when they appear hastening to suppuration. Poultices of the mandragora and mezereum have been employed for this purpose.

Disputes have also arisen respecting the opening of the buboes. We certainly run little risk in suffering them to remain till they are soft, and the fluctuation of matter is evident; but we would then advise opening them, and employing the knife rather than the caustic. The latter is preferable when, from symptoms of irritation, a discharge is necessary before the abscess be quite ripe.

When the abscess is formed, it must be treated according to the usual methods, stimulated, and the constitution supported by bark and wine, if the circulation be languid; but by a contrary plan if irritable

and inflamed. In either case mercury is improper; but, in intermediate circumstances, we may begin our mercurial course with little hesitation.

When sinuses are threatened, the stagnation of matter must be guarded against: if formed, they must be opened. We have seen the opening of a single sinus give such a stimulus to the neighbouring parts, that the sore has soon assumed a healthy, instead of a cancerous aspect, without any other application. When mortification threatens, bark, wine, and opium, are necessary; when cancer, hemlock. Yet we suspect that real cancer has never been the consequence of a venereal bubo. We have never at least seen it in a long practice, nor have been informed of such an event by a competent witness. See LUES VENEREA, and ABSCESSUS INGUINIS.

See Heister's Surgery. Astruc on the Venereal Disease, or Chapman's Abridgment of Astruc. Bell's Surgery. Wallis's Sydenham, vol. i. 143. White's Surgery, 20. Plenck on the Lues Venerea; Swediaur and Bell on the Venereal Disease; Hunter; Foot.

BU'BON, (from *βουβων*, the groin).

BUBONOCE'LE, (from *βουβων*, the groin, and *κηλη*, a tumour). It is also called *hernia inguinalis*, or RUPTURE of the GROIN, when the intestines are forced through the ring of the external oblique muscle of the belly. When through the cavity in the thigh, between the *musculus pectineus* and *sartorius*, it is called *hernia femoralis*, or *cruralis*.

The cause may be great distention of the bowels from wind, violent exercise, as leaping, or lifting burdens. A relaxation of the ring of the muscle is not an uncommon cause, and on this account the disease is sometimes hereditary. In lean persons the ring is also frequently relaxed, and in fat people the weight of the parts will occasionally bring them down.

The signs are, a tumour in the groin, or upper part of the scrotum, beginning at the ring of the abdominal muscle, and extending more or less downward, towards or into the scrotum in men, and the labia pudendi in women. This tumour appears different to the touch, according to its contents. If a portion of the ilium forms the tumour, its surface is smooth and elastic, but much more so if the patient coughs and sneezes. If only a piece of the omentum hath slipped down, the tumour is more flabby when felt, its surface is more unequal, and it makes less resistance to the finger. If both the intestine and omentum have descended, the diagnostics will be less distinct, and it requires generally some experience to assist in judging of what can hardly be learnt by description.

The distinction of bubonocoele is of considerable importance, and the greatest injury has been done by mistaking it for bubo, for *hernia humoralis*, for cancer of the testicle, and hydrocele. Of the symptoms distinguishing it from bubo we have just spoken. *Hernia humoralis*, or a swelled testicle from venereal irritation, is distinguished by the symptoms of its attack; for the latter is preceded by a hardness of the epididymis, followed by a hardness and acute pain of the body of the testicle itself, while the hernia is not equally painful, till external inflammation, and other symptoms of affections of the bowels, sufficiently point out its nature. It could scarcely be supposed that a cancerous tumour

of the testicle could be mistaken for hernia, had we not seen the error committed. The slow progress of the swelling, the scirrhus feel, and the undisturbed state of the bowels, sufficiently discriminate the two diseases. The dropsy of the tunica vaginalis testis is most often mistaken for hernia. This, however, feels more smooth and equable; a fluctuation can be perceived, a transparency, when a candle is placed on the opposite side, is obvious: and if we can observe its progress, we shall find that it begins at the bottom of the scrotum, gradually rising upwards, and the spermatic cord is generally free; while in hernia, the enlargement is felt from above downwards. The increase of the tumour on coughing or sneezing, and the obstructed state of the bowels; above all, its receding or lying back; are fully sufficient, even for the less experienced practitioner, to discriminate the two diseases.

One other complaint should be noticed as sometimes confounded with bubonocoele, viz. the varicocele, particularly the varices of the spermatic cord. These are forced down in coughing, and disappear in a recumbent posture. The distinction is not difficult. When emptied from a recumbent posture, if a finger is placed on the ring, and the patient raised, the tumour will reappear should it be from varices, but not if it is a hernia.

The ring of the muscle so often mentioned, is an aperture in the tendon of the external oblique, formed by the splitting of its fibres. Through this passage the testicles in the foetus, or soon after birth, descend; and the spermatic cord is, by the testicle, drawn down through it. No process, except the occasional accumulation of fat, contributes to close it, and through this aperture the intestines descend. Though authors speak of the ring, yet there are two; for another aperture is formed by the tendons of the internal oblique and transverse muscle behind, and a little on the outside of the other ring. Though we have said nature has not closed the aperture, yet the ring is drawn close by the action of the external oblique; and this action, while it often prevents rupture when it has occurred, occasions what is called strangulation. The term is perhaps improper, as the tendon is not capable of contracting. In reality, the distention of the bowels occasions the contraction of the external oblique, which draws the fibres of the tendon closer; while the distention of the portion of intestine filled with air, contributes to fill more completely the contracted aperture. The internal ring is more muscular, and may be spasmodically contracted.

The symptoms of all intestinal herniæ are those of *ilius*; and in every case of violent colic, the practitioner should always examine whether some hernial tumour can be discovered. The pain is generally most violent at the pit of the stomach, as the omentum, which accompanies the intestine in the sac, is dragged down with it. The pain goes on increasing, incessant vomiting comes on, and what is discharged is at first watery, then bilious, and lastly, feculent; stools are obstinately retained, and mortification closes the scene. Vomiting and hiccough frequently occur in herniæ; and the cause will be obvious when the connection of the omentum with the stomach is considered. The pulse is at first hard, but when mortification and cold sweats come on, it is softer and more regular, but soon becomes small, frequent, and tremulous.

When a hernia comes down, if the patient is strong and plethoric, some blood may be taken, and a clyster injected; the reduction is next attempted.

To reduce the hernia merely by the hand, without cutting or eroding the part, is called *Taxis*; and when it is thus reduced by the hand, if the rupture consisted of a portion of the intestine only, it generally slips up at once. The posture of the patient, if laid on his back, with his heels brought near to his buttocks, assists the return of the protruded parts: if a piece of the omentum is the contents, its return is not so speedy; if there are both omentum and intestine, the latter ascends first, and the former feels flabby, but soon after follows also. Sometimes after the intestine is returned, a soft knotty substance remains unreduced, and resists all the efforts to reduction, until the patient's vessels are emptied by bleeding, repeated purges, and a low diet; the varicous feel which this substance hath, seems as if it was the mesentery with its vessels distended.

In infants the reduction is generally easy, and as they acquire strength they are less subject to a relapse. In the vigour of life the return is generally more difficult, and the neglect or bad management more dangerous.

It often happens that raising the buttocks while the body is depending, will alone succeed. Should this not be the case, the surgeon should grasp the tumour with one hand, press it steadily upwards and outwards, while with the fingers he begins to reduce the last protruded portion. Should he succeed in part, the rest soon follows, and the patient is relieved. If he fail, different plans have been advised.

Of the remedies, copious bleeding is the first, and often an indispensable one. When the patient faints, the tumour often spontaneously recedes. Purgatives have been next employed, and absurdly given by the mouth; we say absurdly, because, by increasing the peristaltic motion *above the tumour*, it rather adds to the disease. It has been usual to join the purgatives with opium to relax the stricture, while the purgative contributed to conquer the constipation. In such cases, however, the purgatives are so often retarded by the opium, as to lose their effect; and should this combination succeed, it must be attributed to the opium only. Purgatives injected as clysters are not liable to the same inconvenience; for the increase of the peristaltic motion *below the tumour*, has a tendency to draw back the intestine. Soap, particularly the black soap, is highly useful in this way; and purgatives of the most active nature, and of every kind, have been employed. The most ready and advantageous one, however, is the infusion of tobacco in clyster. From half a drachm to two scruples of tobacco may be infused in ten or twelve ounces of boiling water for ten minutes, and injected as a clyster. It is not only useful as a laxative, but produces so much languor and fainting, as often to occasion the gut to recede without other assistance. The digitalis also seems chiefly useful, by producing syncope.

It has been usual to apply warmth in every form to the hernial sac, with a view probably of relaxing the ring; but it was not considered that even if this effect was certain, that the flatulent contents of the sac would be enlarged in a greater proportion, and even the substance of the intestine itself. We believe it has seldom succeeded; and when useful, the faintness induced by its

continuance has been the chief cause of the relief. The warm bath for the same reasons has sometimes succeeded, but much oftener failed; and we think that, in many cases, it has accelerated mortification. The contrary method is now more advantageously adopted; ice and snow have been applied with success to the hernial sac. When these cannot be procured, the coldest water, often renewed, has been of service; and water cooled artificially has been used. The most ready way of cooling water is to suspend it in a wet bladder to a current of air, and the effect will be increased if the outside of the bladder be moistened with æther, carefully purified from the acid. A solution of nitre with sal ammoniac will be equally effectual, in the proportion of eight parts to five; and with management, by further cooling water first artificially cooled, all the effects of ice may be procured even in summer. The constant application of cold has thus often succeeded, and it is one of the most valuable improvements of modern practice.

All will in many cases fail, and the operation, though dreadful, and often fatal, must be attempted. Yet there is one further step to avoid it, viz. to dilate or divide the ring, to prevent strangulation, and suffer the tumour to remain. This is the advice of Dr. Monro, and we think it merits more attention than it has received. This operation is not formidable, is not perhaps highly dangerous; and should it be performed hastily and unadvisedly, does not prevent reducing the rupture at a subsequent period. The danger and the severity of the operation have occasioned its being too long delayed; but though it succeeds in some apparently desperate cases, it fails in others where the prospects were more favourable. The external appearances of mortification are undoubtedly among the symptoms which would render it unsuccessful, since mortification takes place in the intestine before it is communicated to the integuments, and is, of course, more violent in degree in the former than the latter part. Feculent or putrid vomitings have been considered as highly unfavourable to success; yet even in such instances the patient's life has been saved. Mr. Cooper thinks that a general soreness in the abdomen is the chief symptom which should prevent the attempt.

In Mr. Home's opinions, the symptoms are influenced by the state of the gut. If no inflammation has taken place in it, the consequences of obstruction only are observable. When inflammation takes place, there is a general soreness, with constant vomiting, that does not relieve, and considerable depression of spirits. When the stricture produces mortification, all the unfavourable symptoms are observed, and a general coldness comes on. The last symptom is decisive against attempting the operation.

To proceed in the operation, the pubes and groin should be shaved; and, in order to have as much empty space as possible for the return of the protruded parts, the patient should be advised to empty his bladder entirely. The patient being then laid on his back, on a table of a convenient height, with his legs hanging easy over the end of it, with a straight dissecting knife an incision must be made through the skin and membrana adiposa, beginning just above the ring of the abdominal muscle, and continuing quite down to the inferior part of the scrotum. Upon the division of the membrana adiposa, some small tendinous bands appear distinct

from each other, lying close upon the hernial sac, which is next to be divided with the utmost caution, as the sac is thinner in some parts than in others: even the external incision of the teguments ought to be made with great care; for although, in by much the greatest proportion of hernial swellings, *the spermatic vessels lie behind the protruded parts, yet on some occasions they have been found on the anterior part of the tumour*; so that, in order to avoid the risk of wounding them, so soon as the skin is divided, the remainder of the operation must be done in the most cautious manner, care being taken to avoid every large blood vessel that makes its appearance. The incision in the sac is best made about an inch and a half, or two inches, below the stricture, and need be no more than such an aperture as will just admit the extremity of the probe. If the probe will pass freely up and down, enlarge the opening with a probe pointed bistoury, sufficient to introduce your finger to divide the whole, remembering to divide it first downwards, which gives more room, and lessens the hazard of the intestines being wounded by the knife, which might easily happen in dividing it in the opposite direction. The fore finger is the best of all directors, and upon that finger a narrow bladed curved knife, with a bold probe point, will be the only instrument necessary to finish the operation. With this knife on the finger the sac should be divided, first downward to the bottom of the scrotum, then upward to the ring. Upon the first division of the hernial sac a fluid is discharged, differing in quantity and colour in different patients. The sac being fairly divided up to the ring, the intestine pushes out, and seems to be more in quantity than it did while in confinement. At this juncture, if the quantity of the protruded intestine is not very great, try to reduce it by first pulling down a little more, for thus, its bulk being lessened, it perhaps may pass without dividing the ring; if this does not succeed, the probe pointed knife, conducted on the fore finger, will immediately divide the upper part of it, and set all free. The sac and ring divided, the contained parts come into view, and, according to their different states, will be variously managed. If sound, immediately reduce them, remembering that the parts last protruded should be first returned. Slight adhesions may be separated with the finger, or snipped with the scissors. If the parts are so adherent as not to be capable of being returned, remove the stricture by dividing the sac and ring, and leave the prolapsed parts in the scrotum as you find them; but this case seldom happens. If the contained parts are mortified, death will be the issue; but if the mortification is not very extensive, return them, and trust to the efforts of nature, and the effects of medicine. If the intestine is mortified, make a ligature and fix it to the wound; thus the fæces will pass out at the aperture, and the patient may live many years after.

Herniæ in women are treated as in men, but in them the disease is less common, as the aperture is much smaller, not requiring the passage of a body so large as the testicle, but only the round ligaments. Women, however, more frequently conceal the disease, and we must be more attentive to the cause of every kind of violent colic. One inconvenience arises from not distinguishing in them the inguinal and femoral hernia, since the tumour in each species is not very distant, and the mode of reduction is different. If the operator feel

with his finger the course of Poupart's ligament, and find the neck of the tumour above its edge, the hernia is inguinal; if below, femoral: as, in the male, the intestine is sometimes not protruded beyond the external ring, and the disease may remain undiscovered.

After the operation, the patient must be laid in bed, with his body somewhat raised, and an opiate administered. A clyster should be soon given, and immediately after its operation, a mild but effectual laxative, as manna, castor oil, or the pulv. *è senna c.* administered. The wound, dressed in the common way, should be secured by a T bandage. The consequent bad symptoms are those chiefly of irritation from air admitted into the cavity of the abdomen, or mortification. Bark and opium are the chief remedies, and must be administered in proportion to the violence and nature of the complaint. The bowels must, however, be kept open with the greatest attention.

When a hernia has been of long continuance, adhesions between the gut and the sac, and between the contiguous portions of the gut, take place. Greater caution must be used in opening the sac when adhesions are suspected; and those between the gut and the sac must be carefully separated. If the disunion of the others be not easy, the intestine should be returned without its being effected. When the separation of the gut from the sac is found difficult, a part of the latter may be separated and returned with the gut.

The omentum often causes much uneasiness. If gangrenous, the diseased portion may be cut off. In general the vessels are small, and little hæmorrhage occurs; but this is sometimes considerable, and it is necessary to tie a vessel, or even two. In this case the ends of the ligature should be brought beyond the wound, and they will soon separate. The method of separating the mortified portion of the omentum by a ligature, is often inconvenient from the irritation it induces, and no injury happens from dividing it.

When a portion of the intestine is mortified, it has been recommended to separate it, and unite the sound portions of the gut by ligatures, or, by placing them in contact, to leave the union to nature. This plan has been suggested by nature occasionally separating a mortified part of some extent, while the canal was not interrupted. It is impossible in this place to enlarge on the minute details which such an operation requires; and the reader will find ample information in Mr. A. Cowper's most excellent work on hernia.

The portion of gut found in hernial swellings is very various, no part of the intestinal canal being entirely exempted from falling down. Hitherto the ileum has been commonly supposed to form the substance of the greatest proportion of such tumours: later and more accurate observation, however, renders it probable that the cæcum, appendix vermiformis, and part of the colon, are more frequently contained in the hernial sacs than any other portion of the gut.

See Pott on Ruptures, Le Dran's Operations in Surgery, Sharp's Operations of Surgery. Lond. Med. Obs. et Inq. vol. iv. Bell's Surgery, vol. i. White's Surgery, 318. Cowper on Ruptures. Monro on Herniæ.

BU'BON GAL'BANUM. See GALBANUM.

BU'BON MACEDO'NICUM. See APIUM MACEDONICUM.

BU'CCÆ, (from the Hebrew term *bukkah*). The

CHEEKS. Hippocrates terms them *cyclos*; the cheek is also called *gomphale*, *gela*, *maxilla*, *melon*. They are the sides of the face; and reach from the eyes and temples between the nose and ears. The upper prominent parts of the cheeks are called *MALA*, which see.

BUCCACRA'TON, (from *buccella*, a morsel, and *κραω*, to mix). Morsels of bread sopped in wine, which formerly served for a breakfast.

Paracelsus calls by the name of *bucella*, the carneous excrescence of a polypus in the nose, because he supposes it to be a portion of flesh parting from the *bucca*, and insinuating itself into the nose.

BUCCA'LES GLANDU'LÆ, (from *bucca*, the cheek). The small glandular bodies on the inside of the cheeks. They open by small holes or orifices through the inner membrane of the mouth. Winslow.

BUCCEA, BUCCELLA. A MORSEL.

BUCCELATIO, (from *buccellatus*, cut into small pieces). A method of stopping the blood by applying lint, cut into small square pieces, upon the vein or artery.

BUCCELA'TON, (from *buccella*, a morsel. *Buccella purgatoria*, and *buccellatus*. A purging medicine, made up in the form of a loaf, consisting of scammony, &c. put into fermented flour, and then baked in an oven.

BUCCE'LLA. See BOLUS, BUCCACRATON, and BUCCELATON.

BUCCINA'TOR MUSCULUS, *constrictor musculus*. The TRUMPETER'S MUSCLE, (from *βουκων*, a trumpet). It is thus named because of its use in forcing the breath to sound the trumpet. It has two distinct beginnings on each side, one tendinous and fleshy from the lower jaw, between the last dens molaris and the root of the fore part of the processus coronæ; the other is fleshy from the upper jaw, between the last dens molaris and the processus pterigoides, from whose extremity also it arises tendinous, being continued between these two origins to the pterigo pharyngæus on one side, and the mylo pharyngæus on the other; from thence proceeding with straight fibres, and adhering to the membrane that covers the inside of the mouth, but without touching the gums of either jaw. It is inserted and lost in the angle of the lip. By its substance on each side it constitutes the cheeks, and through its middle the *ductus salivalis superior* passes. Its use is not only to move the cheeks with the lips, but also to contract the cavity of the mouth by bringing them inwards, and so thrust the meat between the teeth for its better comminution.

BU'CCINUM, (from *buccino*, the trumpet). So called from its trumpet-like shape. The WHELK. Whelks calcined have the same effects as the purple fish, but are somewhat more caustic. The shells filled with salt, then burned in a crude earthen pot, make a good dentifrice. It is a sea shell fish, of which there are many sorts, but the shells are all absorbents.

BU'CCULA, (a dim. of *bucca*). The CHEEK. The fleshy part under the chin.

BU'CERAS, or BU'CEROS. See BOUCERAS.

BUCRA'NION, (from *βας*, an ox, and *κρανιον*, a head). So called because it resembles an ox's head. See ANTIRRHINUM.

BU'CTON. See HYMEN.

BU'FFALO. See BUBALUS.

**BU'PFELI.** A ring made of the horn of a buffalo, which is worn on the ring finger to cure the cramp.

**BU'FO,** (from βας, an ox, and φονος, death). So called because it is death to any cattle which eat them. The **TOAD**; also called *rubeta, rana rubeta*. The toad is of the frog kind, and of the number of those animals which have only one ventricle in the heart. It is much like the frog, but its belly is more inflated, and skin more full of tubercles; it is of an ash colour, with brown, blackish, and yellow spots. It does not croak like the frog, but makes an indistinct noise that is obscure, and like the word *geu*, or rather *bu*, from which some suppose it is called *bufo*. It is said to have its name *rubeta* from *rubus*, because it is often found under bramble bushes.

There is a very poisonous species in America called *cururu* by the Brasilians, and *capio* by the Portuguese.

The common toad was first introduced into medicine from a cure being performed on an hydropic person, to whom powdered toads were given in order to despatch him, but he voided a large quantity of urine after taking them, and soon recovered of his disorder. Since this, toads, gently dried and powdered, have been used as a diuretic, but the present practice rejects them. They have also been applied alive to cancers to suck the virus, a method of extracting it said to be fatal to the animal; the plan is, however, disused, probably from its want of success.

**BUGA'NTIA.** CHILBLAIN. See **PERNIO**.

**BUGLO'SSUM,** (from βας, an ox, and γλωσσα, a tongue; so called from the shape and roughness of its leaf). **BUGLOSS**; called also *buglossum angustifolium majus, buglossum vulgare majus, buglossum sativum*. **GARDEN BUGLOSS.** *Anchusa officinalis* Lin. Sp. Pl. 191.

The garden bugloss is a rough plant, resembling borage, and differing from it chiefly in the leaves being narrow, less prickly, not wrinkled, and of a bluish green colour, and in the segments of the flowers being obtuse. It grows wild on waste grounds in the southern parts of Europe, is cultivated with us in gardens, flowers from June to the end of summer, and in winter it dies to the ground, but the roots continue. It is a name of the *borrago*, and as a medicine is nearly similar, but its roots are less mucilaginous.

**BUGLO'SSUM RADICE RUBRA.** See **ANCHUSA**.

**BUGO'NES,** (from βας, an ox, and γινομαι, to be bred, or generated of). An epithet for bees, because the ancients thought them to be bred from the putrefaction of an ox. See **APES**.

**BU'GULA,** (a dim. of *buglossa*; and said to be so called from its resemblance). **BUGLE.** Called also *consolida Media, prunella Germanis, symphitum medium*, and **MIDDLE CONSOUND.** The sort used in medicine is the *ajuga reptans* Lin. Sp. Pl. 785.

It is a low plant, with round, creeping, and upright square stalks. They bear loose spikes of blue flowers; the leaves are somewhat oval, soft, and set in pairs about the joints of the stalks. It is perennial, found wild in woods and moist meadows, and flowers in May. It is mildly astringent; the root is the most so.

**BULA'T WELA.** See **BETLA**.

**BULBOCA'STANUM,** (from βολβος, a bulb, and καστανον, a chestnut,) *agriocastanum, nucula terrestris, balanocastaneum, bulbocastanum majus et minus*, **EARTH**

**NUT, HAWK NUT, KIPPER NUT, and PIG NUT.** *Bunium bulbocastanum* Lin. Sp. Pl. 349. The *b. flexuosum* of modern authors appears to be specifically distinct, and similar in its qualities.

This root is as large as a nutmeg, hard, tuberous, and whitish. It grows in sandy and gravelly places; flowers in May; is eaten either raw or roasted. It is sweetish to the taste, nourishing, and supposed to be of use against strangury and bloody urine.

**BULBOCO'DIUM,** (from βολβος, bulbous, bulbous, and κωδία, a globe). So called from its round bulbous root. See **NARCISSUS LUTEUS SYLVESTRIS**.

**BU'LBONACH.** (German). Called also *viola lunaris, lunaria major, leucoium lunatum*, **SATIN** and **HONESTY.** *Lunaria rediviva* Lin. Sp. Pl. 911.

The root is knotted, whence the name *bulbonach*; the seeds are large, red, and acrid to the taste. It grows spontaneously in Germany and Hungary, is sown in gardens in England; and is said to be a warm diuretic. Raii Hist. Modern practice, however, rejects it.

**BUL'BUS,** vel **BO'LBOS,** (from βς, a particle of excess, and λαβη, from λαμβανω, to take, because it is easily taken hold of from its roundness). **Blancard.**

**BUL'BUS ESCULE'NTUS,** such bulbous roots as are commonly eaten.

**BUL'BUS VOMITO'RIOUS,** called also *muscaris*, **ASH COLOURED GRAPE FLOWER, muscari obsoletiore flore, hyacinthus racemosus moschatus, sibcadi, diphcadi,** and **MUSK GRAPE FLOWER.** *Hyacinthus muscari* Lin. Sp. Pl. 454.

It hath a leaf as flexible as leather; the root is bulbous, covered with a black rind, and is emetic and diuretic. It grows in gardens about Constantinople, and in other parts of Asia. Raii Hist.

**BUL'BUS SYLVESTRIS.** See **NARCISSUS LUTEUS SYLVESTRIS**.

**BULI'MIA, BULIMI'ASIS, and BU'LIMUS.** See **BOULIMUS**.

**BULI'THOS, and BULITHUM,** (from βας, an ox, and λιθος, a stone). A stone found in the gall bladder, kidneys, or urinary bladder, of an ox. See **CAPRA ALPINA**.

**BULLA.** A **BUBBLE**; a **VESICLE.** An elevation of the cuticle of a large size, irregularly circumscribed, and containing a transparent watery fluid. Clear vesicles arising in the eye, or from burns or scalds, are called **BULLÆ.** Vesicles, with a dark red, or livid coloured base, are usually denominated **PHLYCTENÆ.**

**BULLION,** (from the French *billon*). Gold or silver in the ore, or imperfectly refined.

**BULLO'SA FEBRIS,** (from *bulla, a bubble*). An epithet applied to the bullous or vesicular fever, from the appearance of the eruptions attending it. See **PEMPHIGUS**.

**BUME'LIA,** (from βς, a particle of increase, and μελία, the ash). See **FRAXINUS**.

**BU'NA.** See **COFFEA**.

**BUNIAS, vel BOU'NIAS,** (from βουνος, a hill, because it delights in rugged places.) called also *actine, naphus*: **NAVEW.** It is a plant of the turnip kind, with oblong roots, growing slender from the top to the extremity. Linnæus supposes the wild and sweet *navew* to be varieties only. It is also the *naphus sativa, naphus dulcis, NAVEW GENTLE*—**RAPP, FRENCH NAVEW, SWEET**

NAVEW, and FRENCH TURNIP. *Brassica napus* Lin. Sp. Pl. 931. Nat. order *cruciferae*.

It is cultivated in gardens for the kitchen. The roots are warmer and more grateful than the common turnip, and afford a juice supposed to be pectoral.

The seeds of both sorts are warm and pungent, approaching to the virtues of mustard, but much inferior in their efficacy. Water extracts all their virtues. They yield by expression a large quantity of oil, which is sold under the name of rape oil: the wild sort is cultivated for this purpose. The cake remaining after the oil is expressed retains the acrimony of the seed.

There is a species which Galen prefers to the above; is called *pseudo bunium*, or *napus sylvestris cretica*, or CANDY WILD NAVEW; a variety only. Dale.

BUNITES VINUM, (from *bunium*, wild parsley). WINE of BUNIAM. It was formerly made of *bunium*, two drachms; and must, four pints.

BUNIAM, (from *βουνος*, a little hill; so called from its tuberosity). WILD PARSLEY; also called *daucus pietroselini*, or *coriandri folio*; *saxifraga montana minor*. *Seseli montanum* Lin. Sp. Pl. 375. It grows in stony places, and is somewhat warm and diuretic.

BUPEINA, (from *βη*, a particle of increase, and *πεινα*, hunger). See BOULIMOS.

BU'PHAGOS, (from *βη*, and *φαγω*, to eat). The name of an antidote in Marcellus Empiricus, which created a voracious appetite.

BUPHTHA'LMUM, (from *βη*, an ox, and *οφθαλμος*, *oculus*, an eye; from its resemblance to an ox's eye). OX EYE, or OX EYED, named *boanthemon*. In Myrepsus it is called *crespulum*.

BUPHTHA'LMUM CO'TULÆ FO'LIO, also *cotula flore luteo radiato*, is the camomile like *ox eye*.

BUPHTHA'LMUM GERMA'NICUM, called also *buphtalum tanacetii minoris folio*, *chamæmelum*, *chrysanthemum*, *buphtalum vulg.* COMMON OX EYE.

BUPHTHA'LMUM VE'RUM, called also *buph. perigrinum*, *tenuifolium folio mille folii fere*, *chrysanthemum cotula folio*, *cotula flore luteo radicato*, *cachlan*, OX EYE.

These are all species of the anthemis or buphtalum, resembling the camomile flowers. It is unnecessary to distinguish them, as the flowers of the common daisy are sold for them, and they possess no real medical virtues.

These plants have tender stalks, with leaves like those of fennel, and yellow flowers resembling an eye. They grow in fields near towns. All the species are commended in the jaundice, perhaps because they are yellow.

BUPHTHA'LMUM CRETICUM. See PYRETHRUM.

BUPHTHA'LMUM MA'JUS. See BELLIS MAJOR.

BUPHTHA'LMUS. A DISTEMPERED EYE, (from *βη*, an ox, *οφθαλμος*, *oculus*; from its largeness like an ox's eye). See EXOPHTHALMIA.

BUPLEUROIDES, (from *βοπλευρον*, and *ειδος*, *forma*). A plant which much resembles the bupleurum. *Phyllis nobla* Lin. Sp. Pl. 335.

BUPLEU'RUM BUPLEU'RON, (from *βη*, large, and *πλευρα*, a rib; so called from its having large ribs like filaments on its leaves). HARE'S EAR. *Bupleurum falcatum* Lin. Sp. Pl. 341. Also called *auricula leporis*, *perfoliata*, and *hysophyllon*. It grows on hilly places in France, flowers in July and August, is detersive and diuretic. Dale. For that called BUPLEU'RON AR-

BORESCE'NS SA'LICIS FO'LIO, see LASERPITUM VULGARIS.

BUPRE'STIS, (from *βη*, a cow, and *πρωτω*, to burn; so called because they destroy cattle which eat it). The BURN COW. They are a kind of cantharides, and are possessed in some measure of the same virtues. It is also a name of an herb which was in much esteem among the Greeks as an esculent one.

BURGOUT, a dish composed of oatmeal and water boiled to a moderate consistence, and eaten with butter.—It is a sailor's and a highlander's aliment.

BURHA'LAGA. See EMPETRUM THYMELE FO'LII.

BURI'NÁ, and BURNEA. PITCH. See PIX.

BURIS, a scirrhus hernia, or a hard abscess. Avicenna.

BURNING, or BRENNING, a disease mentioned by old historians, from which authors have unsuccessfully endeavoured to demonstrate the antiquity of SYPHILIS, q. v.

BU'RRHISPIRITUS MATRICA'LIS. Burrhus's spirit for disorders of the womb, is made with myrrh, oilbanum, and amber, in spirit of wine.

BU'RSÆ MUCO'SÆ, (from *bursa*, a purse). Called also *bursæ tendinibus subjectæ*, and *sacculi mucosi*.

It is said that Bellini first observed these bags, but Douglas first described them. Their office is to facilitate the motion of the tendons, where they play upon one another, or upon a bone, and for this purpose they contain a lubricating mucus.

Bell's Surgery, vol. v. 479. Monro's Description of the *Bursæ Mucosæ*, and their diseases.

Mr. Gooch, in his Observations, takes notice of a wound in one of these bags on the side of the knee, which, from the discharge, he concluded to have been from the bursal ligament, but it healed kindly, and led him to suspect that these bags may be the seat of disorders not yet noticed. He hath also given the following list of them.

1. DELTOIDES. A large one situated under this muscle, upon the acromion scapulæ.

2. BI'CEPS BRA'CHII. A small one investing the tubercle of the radius, both on the side where the tendon is fixed, and also on the other side where there is no tendon. It adheres strongly to the whole tubercle, and loosely to part of the supinator brevis, under which it lies, as well as under the tendon of the biceps.

3. ILI'ACUS INTE'RNUS ET PSO'AS. A large thin pliable one is found upon the ischium, beneath the tendons of the iliacus internus and psoas, as they pass down to their insertions in the os femoris. It is attached to these tendons, and to the anterior surface of the capsular ligament; and this sacculus sometimes communicates with the joint.

4. LATI'SSIMUS DO'RSI ET TE'RES MAJOR. One is situated between the extremities of the tendons of these muscles, adhering strongly to them.

5. GLU'TEUS MA'XIMUS. A large thin one, firmly connected by a small part of it to the back of the trochanter, immediately under the termination of the gluteus medius, and loosely attached to the rest of the trochanter and the tendon of the gluteus maximus.

6. GLUTE'US ME'DIUS. A small one situated between the termination of its tendon and that of the pyriformis, adhering to both.

7. *GLUTE'US MINIMUS*. A small thin one, attached to its tendon and the trochanter major.

8. *GE'MINI*. A small one between them and the termination of the obturator internus, connected to both, and to that part of the capsula of the joint which lies under the gemini.

9. *BI'CEPS CRU'RIS*. One is situated between the end of its tendon exteriorly, and the capsular ligament of the knee, adhering to both.

10. *SEMIMEMBRANO'SUS*. A small one lies between its tendon, which runs between the inner condyle of the tibia, and the capsular ligament of the joint.

11. *CRURA'LIS* et *VA'STI*. Behind the tendons of the cruralis and vasti there is a thin but large one, connected to those tendons before they join, and, after their junction, it is fixed to the patella. It also adheres to the capsula of the joint that expands itself over the bone.

12. *GRA'CILIS*, *SARTORIUS*, and *SEMITENDINO'SUS*. Under the extremities of the tendons of these muscles is a large one, adhering to them on one side, and on the other to the capsular ligament of the knee, and on the side where these tendons play.

13. *GEME'LLUS*. A large one lies under its inner head, firmly attached to its tendinous origin, also to the extremity of the semitendinosus, and the capsula of the knee near the anterior condyle.

14. *SOLE'US*. The tendon of the soleus passes over the upper part of the os calcis, between which and the bone lies a large sacculus, and near that is found a glandular body which furnishes a mucous fluid for the more effectual lubrication of these parts, that are in such constant motion in walking.

15. *TIBIA'LIS ANTE'US*. A small one is fixed to the tendon a little before its termination, where it plays on the top of the foot.

16. *PERONE'US LO'NGUS*. One lies under the tendon of this muscle, where it plays over the os cuneiforme, on the outside of the foot.

*BUR'SA TE'STIUM*. See *SCROTUM*.

*BURSA'LIS MU'SCULUS*; so called from its resemblance to *bursa*, a purse. See *OBTURATOR EXTER-NUS* et *INTERNUS*.

*BUSELI'NUM*, (from *βσ*, great, and *σελινον*, parsley). A large species of parsley.

*BU'SSI SPI'RITUS BEZOAR'DICUS*. The BEZOARDIC SPIRIT of BUSSIUS, an eminent physician at Dresden.

Take the spirit of ivory, saturated with subtile oil and salt, two ounces (a. spiritus C. C.); crude sal ammoniac, four ounces; potash, dissolved in water, eleven ounces; amber, half a pound; oil of juniper, half an ounce; distil them in a retort. A salt rises first, and then the spirit, which dissolves this salt.

*BUTEA FRONDOSA* of Roxburgh, is supposed to nourish the insect that furnishes the gum lac.

*BU'TIGA*. See *GUTTA ROSACEA*.

*BU'TINO*. See *TEREBINTHINA*.

*BUTHA'LMUM MAJUS*. See *BELLIS MAJOR*.

*BU'TOMON*, *BU'TOMUS*, (from *βσ*, greatly, and *τεμνω*, to cut,) so named from their sword like shape. It resembles the palms, and its roots are eaten by the Calmucks as food. Its natural order, *junci*, we have already pointed out. It belongs to the *alisimoidæ* of Ventenat. See *IRIS PALUSTRIS*.

*BUTU'A*. See *PAIREIRA BRAVA*.

*BU'TYRUM*, (from *βσς*, a cow, and *τυρος*, coagulum, or cream). *BUTTER*. See *ADEPS*.

*BU'TYRUM CE'RÆ*. See *OLEUM CERÆ*.

*BU'TYRUM CO'CTUM*. See *AZOM*.

*BU'TYRUM ANTIMONII*. See *ANTIMONIUM*.

*BUXB*. An abbreviation of J. C. Buxbaumi *Enumeratio Plantarum*, 1721, 8vo.

*BUXTONIENSIS A'QUA*. *BUXTON WATER*. See *AQUE SULPHURÆE*. *Buxton* is in the Peak of Derbyshire. The waters there are the second in degree of heat among those of this island. The water of St. Anne's well is so pure, that when a gallon of the water was evaporated, the sediment was only fifteen grains; of which one grain and three quarters were sea salt, two and a half selenite, and ten and a half carbonate of lime rendered soluble by an excess of carbonic acid. The specific gravity of this water is precisely equal to that of rain water, when their temperatures are the same; but when first taken from the spring it is four grains in each pint lighter. The temperature of the bath is about eighty-two degrees.

The water of St. Anne's well contains about one sixty-fourth part of its bulk of azotic gas, in which its efficacy may in part reside, and which is quickly dissipated by exposure to the atmospheric air.

This water is alterative, and not evacuant; about a pint in the forenoon is at first taken, and the quantity gradually increased. The cooler the weather, the hotter and more medicinal is the water. It increases the vital heat, is useful in the gout, rheumatism, convulsive asthma, and other nervous complaints, indigestion, loss of appetite from intemperance, contractions of the tendons, urinary diseases, and defective catamenia. Its temperature is the highest at which the cold bath has been used. See *BATHING*.

Short's History of Mineral Waters. Percival's Essays, Med. and Exp. vol. ii. Dr. Hunter's Essay. Dr. Pearson on Buxton Waters.

Besides the tepid mineral waters which are so much employed, there is a fine clear chalybeate water. Dr. Short evaporated a gallon of it; and a scruple of solid matter, above half of which he says was ochre, remained: the rest was a saline matter composed of sea salt and vitriolated magnesia. This water is drunk for the same purposes as other chalybeates.

*BU'XUS*. *Buxus sempervirens* Lin. Sp. Pl. 1394, (*πυκας*, from *πυκάζω*, to become hard; or more probably from the Arabic term *baksa*). The BOX TREE. The Hollanders call it palm tree. It is a well known evergreen, and found wild in some parts of England.

An infusion of the leaves in water hath a fetid smell and a strong bitter nauseous taste, is purgative, and destroys worms. The active matter, or the wood, is of the saline, and not of the resinous kind, consequently differs from the lignum guaiacum, which it is said to resemble as a sudorific and an alterant.

The leaves of the common dwarf box dried and powdered are supposed to destroy worms in children. As much as will lay on a shilling may be given at bed time every night. The oil is used as a depilatory.

*BUY'O-BUY'O*. A sort of pepper in the Philippine Islands. Ray calls it *hiper longum monardi*.

*BY'ARIS*. See *CETE ADMIRABILE*.

BYNE, (from *βυν*, to fill, because in wetting it swells much). See BRASIIUM.

BYNG. A Chinese name of GREEN TEA. See THEA.

BYRE'THRUM, BYRE'THRUS. This word occurs in Forestus, lib. x. obs. 132. Schol. It is a kind of medicated cap or cowl, filled with cephalic drugs, for the head; but no reason or authority can be found for the term, as it appears neither in the Greek nor Latin vocabularies; perhaps the author meant BARETTUM, from the French *barette*, or BERETTUM, from the Italian *berette*, each of which signifies a cap. See CUCUPHA.

BY'RSA, (from *βυρσα*, leather). See ALUTA.

BYRSODE'PSICON, (from *βυρσα*, a skin, and *δερμα*, to curry leather; because it is chiefly used in tanning). See RHUS.

BYSA'UCHEN, (from *βυο*, to hide, and *αυχην*, the neck). People are thus called who, by elevating their

shoulders, hide their necks. The name also of a person who hath a morbid stiffness of the neck.

BY'SMA, (from *βυσμα*, to stop up, obstruct, fill up, constipate, or stuff). The covers, or stopples of any vessels. Some take the *bysma* to be the same with the *amurca*. See BYZEN.

BY'SSUS. A woolly kind of moss. It is a name for the *judendum muliebre*, from its mossy or hairy coat; and a sort of fine cloth worn by the ancients. See also BOMBAX.

BY'STINI ANTIDO'TUS. An antidote often mentioned by Ætius, which seems to be much like Mithridate.

BY'ZEN. In a heap, crowd, or a throng; called also *bysma*. It is derived from the word *βυζω*, or *βυν*, to fill up by stuffing, to condense; thus it expresses any thing that is sufficiently dense. Hippocrates uses this word to express the hurry in which the menses flow in an excessive discharge.

## C.

## C A A

**C.** See NITRUM.

**CAA-APIA.** (Indian.) It is a small low plant, with a root about two fingers' breadth long, as thick as a swan's quill, and sometimes as large as a man's little finger. This root is knotty, and covered with filaments that are three or four fingers' breadth long. Outwardly, it is of a yellowish grey colour, but inwardly white. After being chewed a little it is acrid, and hath nearly the same virtues with *ihcacuanha*, whence it hath also received that name. It is a species of *dorstenia*, the plant which furnishes the contrayerva, and is the *d. Brasiliensis* of Willdenow, vol. i. p. 682.

The Brasilians cure the wounds from poisoned darts with the juice of this root, which they pour into the wound. Piso says it hath the same efficacy against the bite of serpents. See BOJOBI.

**CAA-ATAY'A BRASILIE'NSIS.** (Indian.) It is a plant which grows in Brasil, of no smell, but bitter to the taste. A decoction of it operates powerfully, both upward and downward. It resembles the euphrasia. Raii Hist.

**CAACHI'RA.** See INDICUM.

**CAACI'CA BRASILIA'NIS.** (Indian.) Called also *colubrina Lusitanica*. An herb growing in Brasil, whose leaves resemble those of the male speedwell, somewhat hairy, green above, and white underneath. It is full of a milky juice. When fresh, it is bruised, and applied against venomous bites, Raii Hist. but unknown in the system of the botanists.

**CAA'CO.** (Indian.) The SENSITIVE PLANT, also called *æschynomene spinosa Brasiliensibus secunda*, *herba viva*, *noli me tangere*, *mimosa casta* Lin. Sp. Pl. 1500.

It is a native of Brasil. If the leaves of this plant are touched, they immediately contract, but soon after return to their former state, a singular appearance seemingly connected with electricity, though with some circumstances which oppose this idea. The tops of this plant are noxious, and the roots are said to be their antidote. A decoction is made of a handful of that part of the root which is under ground, boiled in six pints of water for a few minutes, half a pint of which is to be drunk every hour or two, until the patient is well. The root used in this way is an antidote to several poisons in America.

VOL. I.

## C A B

There is another species, called *herba viva tertii species*, *æschynomene spinosa tertii*; *m. pudica* Lin. Sp. Pl. 1501.

**CAAETIMA'Y BRASILIENSIBUS.** (Indian.) Called also *senecio Brasiliensis*.

It is a tall plant which grows in Brasil; the leaves of which have a hot and acrid taste. A decoction of them cures the itch, by washing the parts affected with it. Raii Hist. Its systematic name is unknown.

**CAAGHIGU'GO BRASILIE'NSIS.** (Indian.) *Frutex baccifer Brasiliensis*. A shrub growing in Brasil; its leaves are powdered, and then applied to ulcers as a desiccative.

**CAA-OPIA.** (Indian.) Called also *arbuscula gum-mifera Brasiliensis*. It is a tree growing in Brasil, from the bark of which, if incisions are made, a juice is emitted, which, when dry, resembles the gutta gamba in all respects, only in being somewhat redder. Raii Hist. It is the *hypericum bacciferum* of modern naturalists, but not yet introduced into the Linnæan system.

**CAAPE'BA.** See PAREIRA BRAVA.

**CAAPO'NGA.** (Indian.) The Brazilian name for *crithmum*; also called *trifolia spica*, *crithmum maritimum non spinosum*; *inula crithmoides* Lin. Sp. Pl. 1240.

The leaves and young stalks are pickled for the use of the table, though they are gently diuretic.

There is another species; it is called *perexyl Lusitanis*; it resembles purslane, and is of the same nature as the above.

**CAARO'BA.** (Brazilian.) A tree whose leaves are bitter; a decoction of them promotes perspiration, and is useful in the venereal disease. Raii Hist.

**CA'BALA, CA'BULA, KABALA, CABALI'S-TICA ARS.** The CABALISTIC ART. It is derived from the Hebrew word *kabbalah*, signifying to receive by tradition. It is a science which consists in a mysterious explication of the Scriptures, however they were received. This is the Jewish *cabala*; but, from this original, the word is applied to every mysterious or magical explanation. Paracelsus uses it in a medical sense, saying *cabalistic* signs cannot deceive, *si Dis placet*. Some enthusiastic philosophers and chemists have transplanted it into medicine, importing by it something magical.

**CABALA'TOR.** See NITRUM.

Q q

**CABA'LLICA ARS**, (from *καταβάλλω*, to throw down). A term in gymnastics, importing among wrestlers the art of foiling, or throwing an antagonist down.

**CABALLINE**, (from *caballus*, a horse). See **ALOES**.

**CABA'SSONUS MASSILIE'NSIUM**. A fish found in the Mediterranean sea; also called *lavoronus*.

**CABELIAU**. COD FISH. See **ASELLUS MAJOR**.

**CABULA'TOR**. See **NITRUM**.

**CABURE'IBA, CABURII'BA**. See **PERUVIANUM BALSAMUM**.

**CACAGO'GA**, (from *κακόν*, excrement, and *αγω*, to expel). OINTMENTS, that, by being rubbed on the fundament, procure stools. P. *Ægineta*, lib. vii. ix.

**CACALIA**, (from *κακόν*, bad, and *λίαν*, exceedingly, because it is mischievous to the soil on which it grows,) also called *leontice veterum*, *cacamum*, and *STRANGE COLT'S FOOT*. *Cacalia Alpina* Lin. Sp. Pl. 1170. Nat. order *corymbifera*, Jussieu; *compositæ discoideæ* Lin.

It grows in shady places. Paulus of *Ægina*, and Dioscorides, suppose this to be the *cacanum*; for their virtues are similar to the common sort, for which see **TUSSILAGO**. The *c. sonchifolia*, Lin. 1169, is esteemed a febrifuge, an expectorant, and useful in diarrhœas.

**CACALIA'NTHEMUM**, (from *κακάλια*, and *ανθεμον*, a flower, because its flower resembles that of the *cacalia*), so called by Dr. Dillenius: the CABBAGE TREE, and the CARNATION TREE. *Cacalia kleinia* Lin. Sp. Pl. 1168. Originally it was brought from the Canary islands; and another species came from the Cape of Good Hope. See Miller's Dict.

**CA'CAMUM**. See **CACALIA**.

**CA'CAO**, (Indian); called also *cocoa*, *amygdalus similis Guatimalensis*, *cacava*, *cacari*, *quahoil*, *caravata*, *chocolata*, *avellana Mexicana*, *cacavera*, *cacavata cacao America*; the PEAR BEARING WHOLESOME ALMOND TREE, **CACAO**, and **CHOCOLATE**. It is the *theobroma cacao* of Lin. Sp. Pl. 1100. Nat. order *malvaceæ*. The nut is the only part of the tree used; its shape is nearly that of an almond, but of a much larger size. The shell is dark coloured, brittle, and thin; the kernel throughout is of a brown colour. It is produced by a small American tree, which bears a large red fruit like a cucumber; in this fruit is contained from thirty to a hundred of these nuts. A good tree produces a crop in June, and another in December. The principal distinctions among these nuts are the size, and place from whence they are brought: the larger kind from the province of Nicaragua, in Mexico, are most esteemed. The chief of those brought to England are from Virginia and Jamaica.

Cacao nuts have a light agreeable smell, and an unctuous, bitterish, but not ungrateful, taste. Those from Nicaragua and Caracco are the most agreeable; those from the French Antilles, and our American islands, are the most unctuous. They invigorate the stomach, and are supposed to recruit rapidly the exhausted strength. In diseases of the lungs they are commended in their native soil. In this country they require so much heat that they scarcely ever bear any seed.

The principal use of this nut is for making the liquor known by the name of *chocolate*; which is a mild, unctuous, demulcent, and nutritious fluid. In hectic, scorbutic, and catarrhal disorders; in atrophy, malignant itch, and hooping cough; chocolate, made in the usual way, is said to relieve.

Cacao nuts afford by pressure an oil of the same kind as those that are obtained the same way from other kernels and seeds. This oil is anodyne, used in correcting the effects of corrosive poisons, and in relieving hæmorrhoids. It does not contract any smell, dries readily, and is considered as a good cosmetic. It is said to preserve the flexibility of the joints, and prevent rheumatic affections.

**OLEUM seu BU'TYRUM è NUCLEIS**. The OIL or BUTTER of the CHOCOLATE NUT. Roast the nuts slightly in an iron pan. When cleared from the rind and levigated on a hot stone, dilute them with a proper quantity of hot water, and keep them in a water bath till the oil rises to the top; which, when concremented, is of a brown colour, and, by repeated liquefactions in hot weather, becomes white. Cacao nuts thus managed, afford sometimes more than half their quantity of this vegetable sebaceous matter. As it is not liable to turn rancid by long keeping, it is a proper basis for odoriferous unguents: but its indigestible property renders it unfit for internal use. The mucilaginous pulp contained in the husks, if pressed, yields a cream grateful to the taste; and an emollient for external application of some efficacy. As we owe our knowledge of the tea plant to China, so we are indebted to the Mexicans for chocolate, but they were unacquainted with the sugar cane, which was only brought to St. Domingo in 1506.

To prepare the kernels of the chocolate nuts for use, they bruised them after having separated their husks, then placed them before a clear fire, by which they are so dissolved as to be fit for making into cakes or rolls. These cakes were rendered more solid by adding the meal of maize, and were flavoured with pimento. Such are still brought from New Spain, but the union of the oil with the mucilaginous parts is not complete, and this chocolate often occasions complaints of the stomach.

The Mexicans now mix with these nuts a portion of Indian corn, a few seeds of rocou, and a little vermilion. The French mix with theirs a little cinnamon, vanilloe seeds, and fine sugar. In Paris they make their chocolate for sale as follows: Take of chocolate nuts, freed from their husks, and fine sugar, of each a pound; of cinnamon, finely powdered, two drachms; and of vanilloes half a drachm; beat them well together, and form them into cakes or rolls. "The chocolate of health" contains, however, only canella; and the chocolate of one, two, or three vanilloes, is denominated from the proportion of this condiment. In Spain six pounds of the cacao nut are mixed with three pounds and a half of sugar, seven vanilloe pods, a pound and a half of maize, half a pound of cinnamon, and six cloves, with a drachm of capsicum. The whole is scented with musk, and coloured with the rocou. The choice of the nut is of importance: that from the Caraccos is too dark and dry; the cacao of the islands too unctuous. The best proportion is three parts of the former to one of the latter.

Chocolate is often adulterated in a variety of ways; sometimes common flour, the farina of rice, of lentils, and of pease, or the starch of potatoes, are added to increase its bulk. If ever any additions become necessary, the gluten of the seeds should be wholly excluded, and the fecula only employed.

Some manufacturers are said, by Parmentier, to purchase at a low price the residuum of the cacao nut,

from which the oil has been expressed, and to supply the latter by animal fats, and the yolks of eggs. Others add roasted almonds and gum arabic. It is not an uncommon practice to purchase the unripe nut, and lower its sharp bitter taste with a large proportion of sugar, which is the cheapest ingredient. Chocolate, without any bad intention, is sometimes injured in the preparation. If the nut is not sufficiently roasted, the taste is disagreeable; if burnt, bitter; and the chocolate is black, without the soft unctuous taste natural to it. If the germ is not separated from the two lobes of the seed, it is found in the chocolate, since it resists the weight of the grinding stone.

Good chocolate should in its fracture present no granulated appearance. It should melt in the mouth, leaving a kind of freshness; and when boiled in water or in milk, the consistence should be moderate. Those who cannot bear milk in any other way, find no inconvenience from it in chocolate.

When chocolate tastes in the mouth like paste, when on the first boiling it exhales the smell of glue, or in cooling becomes a jelly, it has been adulterated with farinaceous matters. If little grains are deposited, it is probable that the nut has not been sifted, that it has been badly cleaned, or the coarsest sugar employed. The smell of cheese shows that animal fats have been added; rancidity discovers mucilaginous seeds; and a bitter or musty taste, that the nut is unripe, or too much roasted. We shall add the receipt for making chocolate from Baume's Elements of Pharmacy: Take of Caracco cacao nuts five pounds, of the islands nut one pound, sugar five pounds, fine canella an ounce and half, cloves twelve in number.

After drinking of chocolate, if it is uneasy in the stomach, relief will be found from drinking a tea cupful of cold water.

AN ARTIFICIAL CHOCOLATE is made of sweet and bitter almonds of each an ounce, roasted in an iron pan until they are brown, then wiped clean, and bruised in a mortar, gradually mixing four measures of warm milk, two eggs that have been well mixed with a little cold milk, and as much cloves, cinnamon, and sugar, as may be agreeable to the palate.

CACAPHO'NIA, (from *κακος*, *bad*, and *φωνη*, *the voice*). See PARATHRONIA.

CA'CARI, CACAVIFERA, CA'CAVA, QUAHOTTL, CACAVA'TA. See CACAO.

CACATO'RIA FE'BRIS, (from *caco*, *to go to stool*). A name given by Sylva to a kind of intermittent fever attended with copious stools.

CA'CAVI. See CASSADA.

CACCIO'NDE, a Patronymic, according to Castellus. A pill commended by Baglivi against the dysentery; its basis is the catechu.

CACEDO'NIUM TA'RTARUM. The peccant matter in the human body secreted but not immediately expelled.

CA'CHALOT. See CETE ADMIRABILE.

CACHE'XIA, (from *κακος*, *ill* or *bad*, and *ἔξις*, *a habit*). A BAD HABIT OF BODY. The bad habit which constitutes cachexy consists of a want of vigour of the solid parts, and appears in universal languor, with every mark of defective digestion or assimilation, attended with diminished heat, strength, and activity. The skin is pale, yellow, or dark, and the white of the

eyes often almost transparent. If difficult menstruation is the cause, it is called a *chlorosis*. In Dr. Cullen's Nosology, it is the third class of diseases. He defines it to be 'a depravity of the constitution of the whole or of a great part of the body, without any febrile or nervous disease as the primary one.' This class comprehends three orders; *marcores*, *intumescentiæ*, and *impetigines*.

They are the most disposed to this disease who are naturally of a lax habit, which consists in the softness of the moving fibres, the smallness and number of the vessels, and the slenderness of the tendons. Women are more subject to it than men; men of a phlegmatic habit than those of different one; for such persons are apt to be plethoric, which occasions the liver to be sometimes obstructed: whence the train of consequences which form this disorder.

It is distinguished by a pale white countenance, but often by a yellowish or green colour in the skin, a fulness, coldness, a want of elasticity of the muscles, general feebleness, weariness, a difficulty of breathing on the least exercise, swelled feet, an inactive mind, oppression during sleep, urine white and turbid, the pulse slow and soft, the eye lids œdematous. When a difficult menstruation in girls is the cause, besides these symptoms, there is a pain in the head, a frequent palpitation of the heart, and a preternatural longing for things noxious and unfit for food; pain in the back and loins, a plethora either of the sanguineous or phlegmatic kind, and a sense of weight across the eyes. See CHLOROSIS.

Cachexy is, however, too general an association to be treated of in a single article. It forms with great propriety a natural order of diseases, agreeing in numerous obvious appearances, but differing in their causes. When we speak of it in general, we should say that it is commonly connected with suppressed evacuations, or with causes which influence the digestion and assimilation of the aliment; and, among the latter, scirrhusities of the chylopoietic viscera are the chief. Yet it is a mark of chronic debility in general, from whatever cause it may proceed. One of its distinguishing symptoms is a deficiency of the red globules of the blood. In our examination of the vital fluid we found it difficult to discover their origin, but, like the fibrin, they seem to be connected with tone and strength. The blood without these is of a yellowish hue; and the union of this colour with the red, gives the peculiar tinge styled the flesh colour. It may be considered as a single disease, when unconnected with suppressed menstrua, with jaundice, with scurvy, dropsy, any external tumours or ulcers, or hectic fever. In this view, it is often the effect of long continued anxiety, of 'hope deferred,' of too sedentary a life, indulgence in spirituous liquors, too copious evacuations, particularly those excited by artificial or unnatural means. It is not that the disease differs, but that its cause is not obvious. A scirrhus liver, scirrhus mesenteric glands, an incipient dropsy, impaired digestion, may be produced by all these causes; but it often happens that the symptoms of neither betray the origin of the disease, and our remedies must be directed by general views only.

When the causes of cachexy are obvious, the disease becomes either of those just noticed; nor is the distinction then difficult. We recollect but one instance

in which it is less easy, that is, between cachexy and hectic. In the weak cachectic state, a little fever attends in the evening, which may be easily mistaken for a hectic exacerbation. In hectic, the cough is often trifling and unnoticed, nor is the evening paroxysm strongly marked. In this difficulty, the uneasiness in laying on one side rather than the other, the narrow or deformed chest, the prevailing tendency to consumption in the family, may determine us. But, perhaps, the state of the pulse is the most certain criterion. If in any cachectic state the pulse is generally under 70, and does not at any time greatly exceed 80, we may be satisfied that the lungs are, at least for a time, secure. The young practitioner must, however, recollect, that there is no universal rule in medicine: the most general rules are liable to numerous exceptions. Old age is attended with cachexy, and of a most incurable kind. Indeed, it was long since observed, *senectus ipsa morbus*.

The indications of cure are to correct the bad quality of the juices, to strengthen the stomach, and to invigorate the system.

Hence the diet should be nutritious, cordial, such as nourishes in the least quantities, and repeated often, to afford nourishment adapted to the state of the stomach, without overloading it. No error is more common or more fatal, than, in cases of weakness, to accumulate food. It is not what can be swallowed, but what the stomach can digest, that is serviceable, and it should be of such a nature as to oppose the cause and circumstances of the disorder. Exercise should be constant and regular, but within the compass of the strength. When the primæ viæ are evacuated, medicines which increase the vital heat, as warm bitters, aromatics, and chalybeates, should be given; antimonials relax the stomach, and therefore should be avoided.

It has been usual to give small doses of rhubarb previous to the dinner, that it may digest with the food. This plan, as well as the columbo root given at the same time, may have been useful; but very certainly not in consequence of its being *digested*. Each may give a temporary stimulus, and each may correct the effect of too rapid a digestion of the food, the evolution of an acid. A glass of white wine, previous to the dinner, would be equally, perhaps more, effectual.

Chalybeates are a favourite remedy with many practitioners, and, from their usual effects, they seem well adapted to the disease. We have said that all metallics are apparently tonic, and that chalybeates seem to join an inflammatory stimulus; yet steel is a remedy we have not often employed, and when given, its effects have not been apparently more beneficial than those of tonics and aromatics. But we mean not to set up our opinion as a standard; we are aware on this subject of a little prejudice, and can add, that practitioners of the highest character, and the correctest judgment, recommend chalybeates in this complaint.

In the usual directions, however, there is a want of discrimination which we must endeavour to supply. In every instance of cachexy, visceral obstructions are to be suspected; and we should not accumulate our tonics and stimulants, without relieving overloaded glands by gentle stimulants applied to their excretories, we mean slight laxatives. The warmer resinous purgatives are adapted for this purpose, and among them rhubarb and aloes are the most conspicuous. These may be given

in every variety of form, not to purge violently, but to keep up a regular discharge, and on some days to give an additional evacuation to the usual daily one.

With similar views we have often advantageously given small doses of calomel, not exceeding a grain, or, at most, a grain and a half, every night. We have already spoken sufficiently of the general effects of mercury to explain its use in this case; and as there is always some internal obstruction to dread, its probable utility will be obvious.

See Dr. James's Dictionary, the article CACHEXIA. Boerhaave on the Cachexy. Shebbeare's Theory and Practice of Physic. Lewis's Translation of Hoffman's Practice of Medicine, vol. ii.

CACHE'XIA UTERI'NA. See FLUOR ALBUS.

CACHE'XIA ICTERICA. See ICTERIS.

CA'CHLAN. See BUPHTHALMUM VERUM.

CA'CHLEX. A little STONE OR PEBBLE. Suidas makes it the name of an animal. Galen says that the calceles heated in the fire, and quenched in whey, become astringents, and useful in dysentery.

CA'CHORE. See TERRA JAPONICA.

CA'CHOS, (Indian,) or *solanum pomiferum folio rotundo tenui*. It grows only on the mountains of Peru. It is a shrub of an extraordinary greenness: the leaves are thin and round: the fruit resembles the mad apple, is of an ash colour and a grateful taste. The Indians use it as a diuretic, and to expel concretions from the kidneys. Raii Hist. It is, undoubtedly, a species of solanum, but it does not occur in the Linnæan system.

CA'CHOU. See TERRA JAPONICA.

CA'CHRYS LIBANOTIS. Galen says it sometimes means parched barley; called also *canchry*, or *canchrys*.

CACHU'NDE. A compound cordial medicine, much esteemed by the Chinese and Indians. Zacutus Lusitanus says it is made with amber, musk, aloes, wood, pearls, emeralds, granates, hyacinths, galangals, cinnamon, aloes, &c.

CACHY'MIA. A term in Paracelsus, by which he intends an imperfect metallic body, or an immature metalline ore, which is neither a saline substance nor a metal, but yet almost metal. In fact, he means the metallic calces, which the chemists of that period were unable to reduce.

CACOALEXITE'RIA, (from *κακος*, evil, and *αλεξι-τηριον*, a remedy or medicine). See ALEXIPHARMICA.

CACOCO'HIA, (from *κακος*, bad, and *χολη*, bile). An indisposition of the bile.

CACO'CHROI, (from *κακος*, ill, and *χρῶα*, colour). Such as have an unhealthy colour in the face.

CACOCY'LIA, (from *κακος*, bad, and *χυλη*, chyle). Indigestion or depraved chylickation.

CACOCY'MIA, (from *κακος*, ill, and *χυμος*, humour). For this the barbarous term *kachimia* is sometimes used. A depraved state of the humours.

CACODES. Offensive matter, discharged by the stomach, by stool, or foul ulcers.

CACOE'THES, (from *κακος*, ill, and *ηθος*, mos, a custom,) which, when applied to diseases, signifies a bad quality or disposition. Hippocrates applies this word to malignant and difficult distempers. Le Dran explains it to be an evil ulcer, boil, or sore. Galen and some others express by it an incurable ulcer, that is rendered so through the acrimony of the humours flowing

to it. Linnæus and Vogel use this term much in the same sense with Galen, and describe the ulcer as superficial, spreading, weeping, and with callous edges.

CACOPA'THIA, (from *κακος*, *malus*, and *παθος*, *affectio*). An ill affection.

CACOPHO'NIA, (from *κακος*, *bad*, and *φωνη*, *voice*). See PARAPHONIA.

COCOPRA'GIA, (from *κακος*, *ill*, and *πραττω*, *to do or act*). A disease in those viscera by which nutrition is performed.

CACORRY'THMUS, (from *κακος*, *ill*, and *ρυθμος*, *order*). An epithet of a disorderly pulse.

CA'COS. EVIL, BAD. Also the name of an Indian herb of a red colour: it is diuretic, and useful against calculous disorders.

CACOSI'TIA, (from *κακος*, *ill*, and *σιτος*, *food*). See NAUSEA.

CACOSPHY'XIA, (from *κακος*, *ill*, and *σφυξις*, from *σφύζω*, *to leap or beat like an artery*). A disorder of the pulse in general.

CACOSTO'MACHUS, (from *κακος*, *bad*, and *στομαχος*, *stomach*). A bad stomach; but it is applied to unwholesome food that is bad for the stomach.

CACOTHY'MIA, (from *κακος*, *ill*, and *θυμος*, *the mind*). A vicious disposition of the mind.

CACOTRO'PHIA, (from *κακος*, *ill*, and *τροφη*, *nutrition*). Any sort of vicious nutrition in general.

CA'CTOS, (from *καίω*, *uro*, *to burn*; because its seed is pungent). See CINARA.

CACULE. The Arabian term for CARDAMOMS, q. v.

CADA'GO PA'LI. See CONESSI.

CADAPALA'VA. See MACANDON.

CADDIS. See CARBASUS.

CAD'JUCT. See PHASEOLUS ZARRATENSIS.

CA'DMIA, (from the Hebrew term *kadam*), also *chlimia*, *catimia*. Dioscorides meant by it the recreation which arises from brass whilst melting. Galen applied it to the recreation of brass, and a stone found in some mines called *cadmia lapidosa*, supposed to be the *æruuginosus lapis*. The calamine stone is now called *cadmia*, and the Germans have given this name to cobalt; whence Agricola says, that there are three sorts; one *metallic*, one *fossile*, and one of the *furnaces*; instanced in the succeeding.

CA'DMIA META'LLICA. See COBALTUM.

CA'DMIA FO'SSILIS and LAPIDO'SA. See CALAMINARIS LAPIS.

CA'DMIA FACTI'TIA and FORNA'CUM. See TUTIA.

The burnt *cadmia* receives different names, according to the part of the furnace from whence it is collected; if in its upper part, resembling a cluster of grapes, *botrytes* or *botritis*; if in the lower part, *placitis*. But Schroeder says, that the *botritis* is collected in the middle, the *placitis* in the upper, and the *ostracitis*, which is thin, earthy, and black, in the lower part of the furnace. See also CALAMITIS, and POMPHOLIX, which are truly *CADMIAS*.

CADU'CA, (from *cado*, *to fall*). See VERTIGO, and DECIDUA.

CADU'CUS MO'RBUS, (from the same). See EPILEPSIA.

CÆCA'NIS VE'NA. See CÆCUM INTESTINUM.

CÆCI'LIA, (from *cæcus*, *blind*). The BLIND WORM or SLOW WORM, also called *cæciliate phlopi*, and *cæci-*

*liate phlinus*, Græcis. It is a species of serpent, whose bite is similar in its effect to that of the viper.

CÆCITAS MI'NOR, (from the same). See AMAUROSIS.

CÆCUM INTESTI'NUM. The BLIND GUT; so called from its being perforated at one end only; called also *monomachon*; and by Paracelsus *monocolon*. What we now call the *appendicula cæci*, Rufus Ephesius calls the *cæcum*. But modern anatomists divide the large intestines, which form one continued canal, into three portions. This canal begins by a kind of *sacculus*, or *bag*, which is the first of the three portions, and is called *cæcum*. Dr. Hunter says that it lies on the inside of the os ilium upon the iliacus internus, and is only a round short broad bag, whose bottom is turned downwards, and its mouth upwards. This intestine, which is about three fingers' breadth long, is hid by the last convolution of the ileum. It hath the same bands as the colon, which take their origin from the *appendicula vermiformis*. Winslow observes that this bag lies under the right kidney, and that its diameter is more than double that of the small intestines. Its arteries are from the *mesenterica superior*. The veins are from the greater *mesenteric*, and one of the branches Riolan calls the *vena cæcalis*. The nerves come from the posterior and inferior *mesenteric*.

CÆMENTUM, (from *cædo*, *to beat together*). See CEMENTUM.

CÆMENTUM CUPRE'UM. CEMENT COPPER, called also *ziment cospher*. It is copper precipitated from vitriolic waters, by means of iron. The name is derived from a vitriolic water in Hungary called *ziment*.

CÆSA'REA SE'CTIO. The CÆSARIAN SECTION OR OPERATION; also called *hysterotomia*, and *hysterotomiotia*. It is the operation whereby the fœtus is extracted from the uterus through the teguments of the belly. It is called the *Cæsarean* operation, from Julius Cæsar, who is said to have been brought into the world this way; or from Cæso, who was the first thus taken from his mother's womb.

There are three cases wherein this operation may be necessary.—1. When the fœtus is perceived to be alive, and the mother dies, either in labour, or in the last two months. 2. When the fœtus is dead, but cannot be delivered in the usual way, from the deformity of the mother, or the disproportionate size of the child. 3. When both the mother and the child are living, but the same difficulty attends as in the second case.

Many instances have occurred, in which it has been said that both the mother and child have lived after this operation, and the mother borne children by the natural passages. Heister gives a very distinct account of this operation in his *Surgery*; and of its success in his *Institutes of Surgery*, p. xi. § 5. cap. 113. See also *Mém. de l'Acad. Roy. de Chirurg.* vol. i. p. 623. ii. p. 308. *Edinb. Med. Essays*, vol. v. art. 37 and 38.

Notwithstanding the many successful cases given by different authors, still it appears very probable that most of them have been extra uterine, if we consider the very rare success which has attended the operation in cases where the fœtus has been extracted really from the uterus; for in almost every case which has occurred in England, the operation has proved fatal. It was, however, performed by Mr. James Barlow, of Chorley, Lan-

cashire, where the fœtus was taken from the uterus by the Cæsarean operation, the woman was preserved, and recovered her perfect health. See Dr. Haighton's *Inquiry concerning the true and spurious Cæsarean Operation*; and Mr. Barlow's *Account* in the Medical Reports and Researches, 1798. It is singular, that in the old authors it is said to have been performed frequently with success, and, in some instances, repeatedly on the same woman. We must confess, that we feel no little scepticism on this point, though we cannot see what reason there should be for imposition. The dangerous nature, however, of the operation, even in the best hands, with every assistance, forbids us to believe that it could have succeeded by the rudest means.

To determine the necessity of the operation, the size of the pelvis should be carefully examined. It has been supposed, that if the aperture in any direction was less than two inches, or two inches and a quarter, delivery was impracticable. It has, however, been more lately found, that in a pelvis of an inch and three quarters, delivery with the crotchet might be effected, and, in some instances, even through a less aperture. Delivery, therefore, should scarcely in any instance be considered as hopeless; and almost every attempt should have failed before the Cæsarean section is practised.

If the woman is exhausted and in a dying state while the child is alive, we should certainly attempt to save the latter; but, in general, the life of the mother is by far of the greatest importance. When the child is dead, we should at least wait till we find every effort with the crotchet has failed; though in this difficult emergency, we must occasionally balance between the probability of success in delivery, and the only possible chance the woman can have by attempting the operation before her strength is too far exhausted.

It should not be recommended if the woman is living before she falls into labour, and yet it must be attempted before she has suffered much by her ineffectual throes; for when she is much reduced, the operation is almost sure to be fatal.

To perform this operation, having previously injected a clyster, lay the woman on her back, place a pillow under her right side, to turn the uterus as much as possible on the left; then the operator must make a longitudinal incision, beginning as high up as the navel, on the outside of the linea alba; and carrying it down in an oblique direction towards the ileum, he must cut carefully through the muscles of the belly, and through the peritonæum. He must then introduce a finger into the abdomen, which must be carried along before the point of the knife, in order to prevent the vagina from being wounded. The incision is usually directed to be on the left side, for fear of wounding the liver, though there seems to be more danger of the omentum, or a flexure of the intestines; because as the uterus rises up, it carries the viscera above it, and to each side, but the omentum is frequently found lying between it and the parietes of the belly. The incision into the uterus must be longitudinal, and as long as the external wound will admit, taking care not to wound the Fallopian tubes; the child must be taken out at the incision, and after it the placenta and membranes; blood must be absorbed with sponges: the wound in the uterus must be left to nature, for by its contraction it will be brought into about an inch and a half in length. The external wound is to be sutured

with the interrupted stitch, and then to be dressed as in general. If any considerable vessels are cut through, they should be taken up. We have already observed, that this operation is highly dangerous and very generally fatal. The danger sometimes arises from its having been too long delayed, often from internal hæmorrhage, but more generally from the inflammation excited, and the irritation occasioned, by the access of the air.

In the Lond. Med. Observations and Inquiries, vol. iv. p. 261, is an instance of this operation, which, though unsuccessful, merits attention. In this case the incision was made on the right side; and it was observed that the woman complained but little during the operation, except when the needles passed through the peritonæum in making the sutures: and that the uterus seemed very little sensible of any injury done to it. It is noticed in the remarks on writers who have described this operation, that there is very little satisfaction to be obtained from them; that all they relate is very vague; and that it is indifferent on which side the incision is made, further than as some present circumstance may determine; that the hæmorrhage spoken of by Heister is not so much to be dreaded as he intimates; that the course of the linea semilunaris, as nigh to the outer edge of the rectus muscle as possible, seems to be the most eligible place for the operation.

Paré, Guillimeau, Rolincius, Hoorne, Mauriceau, Solingen, and some others, are violent opposers of this operation; but they only object to it in certain cases, where they thought the practitioners too rash in the attempt. As a substitute for it, the section of the symphysis of the pubes is proposed. (See PUBIS OSSA). Another proposal has been lately offered, that in women whose pelves are distorted, and labour supposed to be impracticable, an attempt should be made to bring on delivery at the end of the seventh month. This, however, is an expedient highly difficult and dangerous, though less so than the operation. It involves, however, many considerations not strictly medical, which we must not pursue in this place. See also an Account of the *Cæsarean Section* by Dr. Vaughan of Leicester. Bell's Surgery, vi. 446. White's Surgery, 451. Osborne's Essays on the Practice of Midwifery. Denman's Midwifery.

CÆ'SARES, CÆSO'NES. Children who are brought into the world by the Cæsarean operation.

CÆTCHU'. See TERRA JAPONICA.

CAF, CA'FA, CA'FAR, (from *caphar*, Arabic). See CAMPHORA.

CAGA'STRUM. Paracelsus used this word to express the morbid matter which generates diseases, and that is not innate, but adventitious. Diseases arising from the *cagrastum* are pleurisy, pestilence, fever, &c.

CA'HVEH, CA'HOÜA. See COFFEA.

CAI'RA, CAI'TCHU. See TERRA JAPONICA.

CAJAH'A'BA. An Indian plant which adheres to trees like ivy; the natives bruise it, and bind it upon fractures. Raii Hist.

CA'JAN, or CA'YAN. *Phaseolus erectus incanus siliquis torosis, thora parou, pisum arborescens; cytizus cajan* Lin. Sp. Pl. 1041. A shrubby plant, with pods containing four reddish peas. A decoction of the leaves restrains the hæmorrhoids when excessive. Raii Hist.

CA'JEPUTIO'LEUM. An oil distilled from the leaves of the *melaleuca leucandron* Lin. not included in his own edition of the species *plantarum*. The tree is of the na-

tural order, *myrtoïdes*, whose wood is useful from its not corrupting in sea water. Its bark is reproduced like cork. The oil is highly fragrant and aromatic, and a few drops of it inclosed in a box will destroy insects which infest the collections of natural historians, particularly among the papilios. It is of a green colour; its smell resembling turpentine, and its taste peppermint. It is considered as a stimulant, carminative and emmenagogue; is highly commended in flatulent colic, in spasms, and in paralysis. Externally it is applied to piles; to the mouth, in palsy of the tongue; and to diseased teeth, which it is said soon to destroy. In the Moluccas also, it is used externally as an aphrodisiac. The dose is from four drops to ten, frequently in a day, but it is seldom used in this country. It is said to dissolve very perfectly the caoutchouc.

CA'JOU, CA'JUM. See ACAJAIBA.

CA'LABA. INDIAN MASTICH TREE; *catophyllum inophyllum* Lin. Sp. Pl. 732. It hath rosaceous flowers, which are followed by a fleshy fruit that includes a nut. This tree is a native of the warm parts of America. From the trunk and branches a gum, called *tacamahac*, or green balm, resembling the gum mastich, issues, which is accounted vulnerary, resolvent, and anodyne. The *c. calaba* affords no balm of this kind, but the seeds are eatable.

CALAMARIE, (from *calamus*, a reed). An order of plants of the reed kind.

CALAMA'RY. See SEPIUM OS.

CALAM'BAC, CALAM'BOUR. (Indian.) See AGALLOCHUM.

CALA'MEDON, (from *καλαμος*, a reed). A species of fracture which runs along the bone in a right line, but is lunated in the extremity.

CALAMI'NA, CALAMINA'RIS LA'PIS, (from *calamus*, a reed; so called from its reed like appearance). CALAMINE STONE, CADMIA, or CATHMIA; also called *cadmia lapidosa ærosa*, *cadmia fossilis*, CALAMITE, CALAMY, and CALAMINARIS STONE.

It is a metallic mineral, of a whitish or yellowish colour, and, in a state of purity, transparent, variously mixed; it is heavy and hard; of a middle nature betwixt stone and earth, occurring in copper mines, and those of lead and iron; it is found in England, Germany, and other countries, either in distinct mines, or intermixed with the ores of lead or other metals. It is a calx of zinc, and sometimes contains a small portion of iron; its specific gravity 3.5236, electrical by heat, volatile, rising in whitish flowers, with a bluish flame. Dissolved in the nitrous acid, it becomes gelatinous. Haüy thinks the calamine a pure ore of zinc without any carbonic acid; but Mr. Smithson, in the Philosophical Transactions for 1803, analysed the calamine from Bleyberg, from Mendip hills in Somersetshire, and from Derbyshire. In each he found carbonic acid; viz. in the first 0.135; in the second 0.352; in the third 0.348. The calx of zinc was respectively 0.714, 0.648, and 0.652. The electric calamine from Hungary contained quartz and calx of zinc only. It is generally exposed to heat before it is brought into the shops, in order to separate some sulphureous and arsenical particles, which it is supposed to contain, and also to render it more easily reducible into powder.

If this ore is not already calcined, it must be heated

to a strong red heat, then quenched in water; and this process must be repeated three times. Before calcination it is frequently of a grey or red colour; but when calcined it is yellow.

It is an error of some writers to say that the *calamy* is a recrement of melted copper, and that tutty is a recrement of melted brass; though it is true that the best *calamine* is what sticks to the iron rods used in stirring the matter in the furnaces while brass is making.

Though the *calamine* stone is an ore of zinc, it is not the only one; for zinc is found in the ore of lead, and of other metals. The principal use of this mineral is for changing copper into brass, which it does by its metallic part mixing with the copper while it is in a state of fusion. See *Æs*.

For medicinal uses, the *calamine*, after being calcined, should be levigated to an impalpable powder; it is then called *lapis calaminaris*, ppt.; for the mode, see COMMUNITIO. When thus prepared, it is useful in collyria, as an astringent and corroborant, in defluxions of thin acrid humours on the eyes, in obfuscations of the cornea, and in ointments for cutaneous exulcerations. If it is exquisitely fine, it acts as an absorbent or desiccative; but if not, it is an escharotic. In the Medical Commentaries it is recommended, by Dr. Adair, in doses of from five grains to a scruple, in the diarrhœas of cachectic patients as a corroborant.

CERA'TUM EPULO'TICUM. CICATRISING CERATE of the London college, now called CERA'TUM LA'PIDIS CALAMINA'RIS. CALAMINE CERATE is made with olive oil, a pint; yellow wax, calamine prepared, of each half a pound: the wax is melted with the oil, and, as soon as the mixture begins to thicken, the *calamine* gradually added and stirred till it is quite cold. This hath been called *ceratum Turneri*. Dr. James says that he remembers to have met with a like cerate in a publication by an old English surgeon who preceded Dr. Turner. The Edinburgh college calls it *ung. lapidis calaminaris*.

The MAGISTRY OF CALAMINE consists of the muriated calamine, precipitated by the volatile alkali, and carefully washed. In doses from three to seven grains it is emetic and cathartic. See Neuman's Chemical Works. Lewis's Materia Medica, and the Dictionary of Chemistry, 4to.

CALAMI'NTHA, (from *καλα μινθη*, good mint). CALAMINT. *Melissa calamintha* Lin. Sp. Pl. 827. A perennial plant, that flowers in July and August.

CALAMI'NTHA ANGLICA. FIELD CALAMINT; called also *calamintha pulegii* odore, *nepeta agrestis*, *calam. fol. ovatis*, and SPOTTED CALAMINT. *Melissa nepeta* Lin. Sp. Pl. 828. The leaves have much of the smell of pennyroyal and spearmint, but hotter, and their virtues are similar to a mixture of both; water by infusion extracts all their virtue, and by evaporation it carries off all the flavour. By distillation with water they give out a large portion of essential oil, pungent to the taste, and strong of the herb: the decoction, after the oil is carried off, is rough, bitter, and aromatic. Rectified spirit of wine extracts the virtues of this herb the most completely.

CALAMINTHA HUMILIOR. GROUND IVY. See HEDERA TERRESTRIS.

CALAMI'NTHA MA'GNO FLO'RE. MOUNTAIN CALAMINT,

with a large flower; MOUNTAIN MINT, the GREATEST, and the more excellent CALAMINT. *Melissa grandiflora* Lin. Sp. Pl. 827. It is a native of the southern parts of Europe, and raised in our gardens; hath a moderately pungent taste, and a more agreeable one than any of the other *calamints*. It is a bitter stomachic.

CALAMINTHA MONTANA is the common *calamint*; named also *calamintha vulgaris, et officinarum Germaniæ*. *Melissa calaminta* Lin. Sp. Pl. 827.

It is found on the sides of the highways, but it is not so common as the field species, nor are its leaves so powerful in their medicinal qualities, not having the smell of pennyroyal. All the *calamints* are slightly aromatic, less so than the other mints, and are used as stomachic; sometimes, without, however, any foundation, as expectorants.

CALAMINTHA PALU'STRIS. See MENTHA CATARIA.

CALAMITA. See STYRAX and MAGNES.

CALAMITIS. A name of that factitious cadmia which, by fixing to iron rods, acquires the figure of a reed. See POMPHOLIX.

CALAMUS, (from the Arabic term *kalam*, or *kelemus*). The stalk of any plant. See CAUDEX.

CA'LAMUS AROMA'TICUS. SWEET SCENTED FLAG; also called *diringa, jacerantatinga, acorus verus, typha aromatica, clava rugosa*. It is the *acorus calamus* Lin. Sp. Plant. 463. Nat. order *typhoides* of Jussieu.

The names of *calamus aromaticus* and the *acorus* differ: the first is a stalk of an eastern reed, which is slender, hollow, white, and of a fragrant smell; it is also called *calamus odoratus*, and *arundo Syriaca*, but is probably only a variety of the *acorus calamus*,  $\beta$ . Lin. 463.

The sweet flag is a plant with long narrow pointed leaves, like those of the common iris, and of a bright green colour; they are divided by the longitudinal rib into two unequal proportions, one of which is smooth, the other transversely wrinkled; the flowers are imperfect, and stand thick together, forming an elegant spike; the root, which spreads obliquely under the surface of the earth, is long, crooked, full of joints, about an inch thick, somewhat flatted, externally of a greenish white colour, which changes in drying into a brownish yellow, internally white, and of a loose fungous texture. It is found in rivulets and marshy places in many parts of England and in Holland. The stalk dies in winter, but the root is perennial.

The dried roots are brought from the Levant, but those of our own growth are preferable. Dr. Alston says that this root is aromatic, stomachic, and carminative. As an *aromatic*, though not heating, like the spices, it promotes the fluid secretions, is of use in gangrenes, both internally and externally, agreeably stimulates, and produces a pleasant sensation in the mind. It has been deemed useful as a warm stomachic, and renders other bitters more grateful and carminative. It is recommended in vertigo proceeding from a weakened stomach, and has been said to have cured intermittent fevers after bark had failed: it seems to add to the efficacy of the bark, particularly where the stomach is in a torpid state. The aroma is fixed, and may be preserved many years. When fresh gathered, the scent is not agreeable, but somewhat like that of leeks; by dry-

ing, the alliaceous odour is lost. That which is sound, tough, and whitish within when broken, is best.

Water dissolves the bitter part of this root, and spirit the *aroma*. In distillation with water it sends up a very small portion of essential oil, leaving a nauseous bitter in the decoction.

More agreeable bitters supersede its use, but it is sometimes a substitute for gentian, and for other gently warm bitters.

CA'LAMUS AROMA'TICUS ASIA'TICUS is the ASIATIC SWEET FLAG; *acorus calamus verus, var.  $\beta$* . 436. It grows in both the Indies. Its root agrees in virtues with that of our own growth.

CA'LAMUS RO'TANG; *calamus rotang* Lin. Sp. Pl. 463. See SANGUIS DRACONIS.

CA'LAMUS ODORATUS. See CALAMUS AROMATICUS.

CA'LAMUS SCRIPTO'RIOUS. A cavity of the brain, near, or in the fourth ventricle, is thus named because it resembles a quill.

CALBIA'NUM. The name of a plaster in Myrepsus.

CALCA'DINUM. See VITRIOLUM.

CALCA'DIS. See VITRIOLUM ALBUM, and ALCALI. CALCA'NEUM, CA'LCAR, CA'LCIS OS, (from *calx*, the heel). PT'ERNA. The HEEL BONE. It is the largest bone in the foot, of which it is the posterior part, and in some measure the basis. The large tendon, called tendo Achillis, is inserted into this bone.

If injured in its fore part, it may safely be amputated.

CALCA'NTHOS, CALCANTHUM, (from *χαλκος*, brass, and *ανθος*, flores, flowers of brass). See VITRIOLUM.

CA'LCAR. See CALCANEUM.

CALCA'RIOUS LAPIS, (from *calx*, lime). See CALX.

CA'LCATAR. See VITRIOLUM.

CA'LCATON. See ARSENICUM ALBUM.

CALCATRE'POLA. See CALCITRAPA.

CALCE'NA, CALCENO'NIUS, CALCE'TUS. Paracelsus uses these words to express the tartarous matter in the blood; or that the blood is impregnated with tartarous principles.

CALC. MUS. An abbreviation of Museum Calceolarium Veronense.

CALCE'TUS. See CALCENA.

CA'LCEUM EQUINUM, (from *calceus*, a shoe, and *equus*, a horse; so called from the figure of its leaf). See TUSSILAGO.

CALCHI'THEOS, (from *καλλιον*, purple). See ÆRUGO ÆRIS.

CALCHOIDEA OSSICULA, (from *χαλιξ*, a chalk stone, and *ειδος*, forma). See CUNEIFORME OS EXTERNUM.

CALCI'DICUM. The name of a medicine in which arsenic is an ingredient.

CA'LCIFRAGA, (from *calx*, a stone, and *frango*, to break). BREAKSTONE. An epithet given to the herb *scolopendrium* or *spleenwort*, in Scribonius Largus. See LINGUA CERVINA.

CALCIGRADUS, (from *calx*, the heel, and *gradus*, a step). Hippocrates means by it, one who, in walking, lays much stress upon the heels.

CALCINATIO, (from *calx*, to burn to a calx or

*friable powder*). Also, *concrematio*, *deflagratio*, *combatio*, *combustura*, *ambatio*. The *calcination* of a body is, properly speaking, its exposure to the action of the fire which produces some change in it. This change is generally effected by separating the more volatile from the more fixed parts of any compound body; or the destruction of any principle capable of inflammation.

Bodies are deprived of their volatile parts by *calcination*, in the instances of burning calcareous stones to convert them into quick lime, which is effected by the separation of the carbonic acid and water; in the exposing gypsum, alum, borax, and several other salts, to the fire, which deprives them of the water that is necessary for their crystallization; and in the roasting of minerals, which carries off their sulphur, arsenic, and other volatile contents.

It was formerly supposed, that an inflammable principle gave to metals their distinguishing splendour, and other properties. As this was consumed in the fire, they were said to be reduced to the state of a calx. It is now, however, found, that the calx is the compound body containing air; but, as the change is produced by fire, we still use the term calcined.

There is an evaporation of volatile parts, and a change to the state of a calx, without any sensible combustion, in exposing imperfect metals, combined with vitriolic and nitrous acids, to a due degree of heat; in this process the acid rises, and is at the same time decomposed, giving to the metal the oxygen necessary to reduce it to a calx. In the same way acids act by solution, calcining metals without the aid of fire, by being themselves decomposed.

*Calcination* is said to be actual, when effected immediately, and only by the action of fire; and potential, when a solvent is used to corrode the metal.

To this head belongs the burnings of vegetable and animal matters; otherwise called *USTIO*, *INCINERATIO*, or *CONCREMATIO*.

There are several species of calcination, by which different degrees of the same effect are produced, and thus *calcination* is perfect or imperfect: the first is where the utmost change, except vitrification, is brought about; the second is where the circumstances of the process are limited in proportion to the change intended.

The *calcination* of metallic bodies, gold and silver excepted, is promoted by nitre. This salt exposed to the fire in conjunction with an inflammable substance, extricates the inflammable matter, but bursts with it into flame, accompanied with a hissing noise: this process is called *DEFLAGRATIO*, or *DETONATIO*. To understand the principle of this operation it must be observed, that the afflux of air is necessary to the support of fire; and that nitre, or any thing containing its acid, will supply the air.

The manner of operation varies according to the nature of the matter to be *calcined*, and may, according to the principle on which it is performed, be distinguished into three kinds, *COMBUSTION*, *CALEFACTION*, and *DETONATION*.

*CALCINATION* by *combustion* is where the body kindled supports, with the assistance of the air, the fire which *calcines* it, as in the instance of coals in the culi-

nary fire. Vegetables are thus *calcined*; and the operation is sometimes alled *INCINERATION*.

*CALCINATION* by *calefaction* is where the *calcining* heat is not generated in the body itself, but imparted to it from external fire. The methods are as various as the different kinds of matter thus treated; and in the management, regard must be had to the substance of the containing vessel, for some should be made of iron, others of glass or clay; and the heat must be differently regulated, or else vitrification, instead of *calcination*, may ensue. *Calcinations* of this kind are expedited by the increase of surface which is given to the calcined matter, and the copious admission of air through that part of the furnace where the matter is placed, by stirring it with a spatula, by previous pulverisation, and by raking off the calx from the surface of the metal, as fast as it appears. It should be further observed, that if any coal, or other inflammable matter, that does not contain a mineral acid, be suffered to fall on the calcining matter, *calcination* will be prevented; and part of what is calcined will be revived or reduced, that is, it will return into its metallic form again.

*CALCINATION* by *detonation* differs from combustion only in this: in the latter the assistance of air is necessary; in the former this want is supplied by the nitre that is added to the matter, which, producing a quicker and more intense fire, both shortens the operation, and, in some instances, renders it more perfect. Detonation is thus performed: a proper quantity of nitre is mixed with the matter to be calcined, a crucible is heated red-hot, then the matter thus mixed is gradually thrown in, an explosive effervescence soon follows. When it has ceased, another portion must be projected, till the whole is calcined. The crocus antimonii, and some other medicines, are thus prepared. A portion of the alkaline basis of the nitre sometimes joins with the calcined matter; but it may be separated by repeated washing with warm water: this is called *EDULCORATION*.

The metals which melt before ignition, are calcined by keeping them in fusion for some time. Those metals which require a strong fire to melt them, calcine with a much less heat than is sufficient to make them flow; hence the scorification, or burning, of such iron or copper vessels as are long exposed to a considerable fire without defence from the air.

In *calcination* the metals visibly emit fumes; yet the weight of the calx proves greater than that of the metal employed from the oxygen absorbed. Metallic calces are revived into their metallic state by fusion with any animal or vegetable inflammable matter.

Except those of lead and bismuth, all the metallic calces require an addition to make them melt in the strongest fire that can be made in common furnaces; and the additions, called fluxes, chiefly consist of a mixture of fixed alkaline salt with some inflammable matter. As these fluxes not only fuse the calx, but also revive it into metal, they are sometimes called reducing fluxes; of which the following is one of the chief, called the *BLACK FLUX*.

Take of nitre one part, and salt of tartar two parts; grind them well together, then set the mixture on fire, by throwing in a bit of red hot coal; cover the vessel, and suffer them to burn until the whole is changed into a black alkaline coaly mass.

R r

Metallic calces mixed with twice their weight of this black flux, and exposed to a proper fire in a close covered crucible, melt and resume their metallic form. But though the calx was heavier than the metal of which it was formed, on reviving to its original metallic state its weight is less than at the first.

See Newman's Chem. Works, Lewis's Materia Medica, the Dictionary of Chemistry.

**CALCINA'TUM**, also **CINIFICATUM**. Terms applicable to calcined substances.

**CALCINA'TUM MA'JUS**. This term is applied to whatsoever is dulcified by the chemical art, such as dulcified mercury, lead, and the like substances, which are very speedily consolidated.

**CALCINA'TUM MA'JUS POTERII**, is mercury dissolved in nitrous acid, and precipitated by salt water. Poterius used it in the cure of ulcers.

**CALCINATUM MINUS**. Any thing sweet by nature, as sugar, manna, tamarinds, &c.

**CALCINO'NIA**. See **CALCENA**.

**CAL'CEIS VITRIOLA'TÆ CATAPLA'SMA**. **CATAPLASM OF PLASTER OF PARIS**. Mix plaster of Paris with water to a proper consistence, and, whilst soft, apply it to the ulcer, where it will harden, and must be suffered to remain for two or three days before it is removed: where want of vigour is apparent in an ulcerated part, it is considered as useful. The principle upon which it is employed has never been well explained, nor has experience yet confirmed its utility.

**CAL'CEIS A'QUA**. See **CALX**.

**CAL'CEIS VIVÆ FLO'RES**. See **AQUA CALCIS**, under **CALX**.

**CAL'CEIS OS**. See **CALCANEUM**.

**CALCITA'RI**. See **ALCALI**.

**CALCITE'A**. See **VITRIOLUM**.

**CALCITEO'SA**. See **LITHARGYRUM**.

**CAL'CITHOS**. See **ÆRUGO ÆRIS**.

**CALCITRA'PA**. **COMMON STAR THISTLE**; **STAR Knapweed**; *carduus stellatus*, *jacea ramosissima*, *stellata*, *rupestris*; *centaurea calcitrapa* Lin. Sp. Pl. 1297.

It grows near highways, on commons, and flowers in June. The leaves are bitter; a drachm of the seed, in a glass of wine, is said to expel viscid matter which obstructs the urinary passages: the root is used against the gravel, and the stone in the bladder; and the bark of the root is extolled in the nephritic colic. It should be gathered about the end of September, and, when dried, the dose is a drachm. It scarcely differs, however, in its effect from other bitters, and is now little used. Dale.

**CALCITRA'PA OFFIC.** **ST. BARNABY'S THISTLE**; called also *carduus stellatus lutea*, *carduus solstitialis*, *spina solstitialis*, *jacea stellata*, *jacea lutea capite spinosa minori*, and *leucanthe veterum*. *Centaurea solstitialis* Lin. Sp. Pl. 1297.

It is commended as an anticteric, anti-cachectic, and lithontriptic, but is in reality only a weak tonic, perhaps an antacid. Dale.

**CALCOÏDEA OSSICULA**. The same as *chalcoides ossicula*. See **CUNEIFORME OS**.

**CAL'COTAR**. See **VITRIOLUM**.

**CALCULIFRAGUS**, and **CALCIFRAGUS**, (from

*calculus*, a stone, and *frango*, to break). The scolopendrium or the pimpnel is thus styled, but they have no lithontriptic power.

**CALCULO'SUS**. Afflicted with the stone.

**CALCULUS**, (from *calx*, a lime stone). **THE GRAVEL and STONE**. The Greeks call this disorder *lithiasis* and *adamitum*; the Latins name it *calculus*; and in English we understand by *gravel*, small stones that pass from the kidneys through the ureters in a few days; and by the *stone*, a calculus concretion in the kidneys, or in the urinary bladder, which is too large to pass, or at least without great difficulty. *Nephritis*, in modern practice, is confined to an inflammation of the kidneys. See **NEPHRITIS**.

When a disposition to form minute calculi exists, we often find nephritic paroxysms, as they are styled, which consist of pain in the back, shooting down through the pelvis to the thighs; sometimes a numbness in one leg, or a retraction of either testicle; symptoms arising from the irritation of a stone passing through the ureters as these cross the spermatic cord, or the nerves passing to the lower extremities. These pains, often violent, are terminated by the painful discharge of small stones through the urethra; and the patient is for a time easy. What, however, is meant by the **STONE**, is a more serious and violent disease. It is singular that these discharges of small gravel do not usually terminate in stone. Many have experienced them during a long life, without any more serious inconvenience: while the latter is a disease chiefly of the young, and seemingly depending on a seminum, not easily explained. If the stone attacks persons more advanced in age, it is often the consequence of paroxysms of gout, long protracted, and terminating imperfectly. Of nephritic paroxysms we must again speak, and shall now confine ourselves to *calculus*. It is not, like nephritis, usually attended with sickness of the stomach, unless the stone is confined in the cavity of the kidney, called its pelvis; for it is with affections of this part that the stomach seems to sympathise. Its commencement is marked only by frequent inclination to make water, pain during the discharge, and the stream often suddenly interrupted. It is a remark of Le Dran, that if there is pain while the first portion of the urine is discharged, the stone is small; if when the last, it is large: if, during the whole time, it does not proceed from a calculus. It is singular, also, that the pain is not in proportion to the size of a stone, for a small calculus will produce violent fits of pain; a large one often very inconsiderable inconvenience. The pain from calculus is by no means constant: it comes on in violent paroxysms, which induced Hoffman to suppose it owing to spasm. All the parts adjoining are forced down, particularly the rectum, giving the sensation of an urgent necessity of having a motion. In many instances the patient can lie most easily on one side, and on turning feels a weight rolling to the opposite side. In the intervals of the paroxysm he is often perfectly easy. These symptoms will generally ascertain the existence of a calculus; but we have often better evidence by the introduction of a catheter. With this instrument we can search through the bladder, and feel a stone. Yet it is sometimes so small as to escape it; and, by some unaccountable accidents, after many trials it is not

felt. It is then in a moment caught, again escapes, and can be discovered no more. It is equally singular that an inexperienced surgeon will sometimes discover it, when the most able operator has been foiled. The stone is sometimes covered with a membranous coat, and then the catheter does not convey the proper sensation to the operator's hand: and it has happened, that when the stone has been once felt, at the moment of the operation it could not be again discovered. This may have been owing to its having forced its way through the fibres of the bladder, carrying with it the internal coat, which thus formed a covering for it on the outside of its cavity: and this, we were informed by the late Dr. W. Hunter, was the case with one of the persons on whom Mrs. Steevens' medicine was tried, previous to her receiving the parliamentary reward. The stone, after taking the medicine, was not to be found; and, on the death of the patient, it appeared not to have been dissolved, but to have escaped detection in this way.

The nature and source of the calculus have been long unknown; nor, at this moment, is either indisputably ascertained. Calculi differ in all their external properties; they differ also in the facility with which they yield to different solvents, but their component parts are singularly uniform. The calculus, when single, is usually oval; when there are more, the shape is more irregular, and still more so in proportion to the number in the bladder. They are usually laminated; the laminæ of different thickness, and irregular in their direction. The colour is occasionally white or brown, or resembling that of a mulberry in this respect, as well as in irregular points. The white laminæ are usually on the outside, the brown in the middle, but the colours never alternate.

The calculus was always concluded to be sand or stone; nor was a hint beyond this idea started till the time of Van Helmont, who, catching a ray from the meteoric visions of Paracelsus, concluded it to be a coagulation of the urine by means of a volatile spirit. Hales undoubtedly threw a considerable light on its nature; but the first regular analysis was made by Scheele; and, about the same time, Bergman exerted his penetrating genius in the same pursuit. They were followed by Morveau, Fourcroy, Woolaston, and Pearson. To pursue the history, which, on the whole, would be neither unentertaining nor uninteresting, would, however, fill a disproportioned space in this work. We shall, therefore, give the analysis of Fourcroy as contained in the latest publication on the subject, the first volume of the *Annales du Museum National*, p. 93, &c. and add the experiments of Dr. Pearson, which differ from Fourcroy's in some essential respects.

M. Fourcroy found, on analysis, twelve different substances in the various calculi found in the body:—the lithic acid, first discovered by Scheele; urats of ammonia and soda; phosphat of lime; acid phosphat of lime; ammoniaco magnesian phosphat; oxalate of lime; carbonate of lime; flint; spermaceti; bezoardic animal resin; and gelatine. The *uric acid* is of a yellowish colour, from the light straw to the reddish yellow colour of bark. It is in fine laminæ, but brittle, though susceptible of a beautiful polish. It is pure only in human urine, and forms the red sediment de-

posited after fevers, paroxysms of gout, &c. It is insoluble in cold, scarcely soluble in hot, water; softened, and in part dissolved, by alkalis, at least with the assistance of a little water; but unaffected by acids, except that the oxygenated muriatic acid changes it into the malic acid.

The *urat of ammonia* was first discovered by Fourcroy: it differs little in appearance from the acid, except that its laminæ are less sensibly streaked. It sometimes forms the whole of a calculus. It is scarcely soluble in water, except with excess of ammonia, and is decomposed by all the acids, rapidly by the fixed caustic alkalis.

The *urat of soda* was first discovered by Mr. Tennant in arthritic concretions, but is not an ingredient in urinary calculi. It consists of friable fragments, without any regular arrangement, and certainly combines some animal and gelatinous matter.

*Phosphat of lime* is a very frequent component part of urinary concretions. It appears in three different forms, viz. a granulated, bony substance, susceptible of a fine polish, like the pretended calculi of the pineal gland, the salivary, lachrymal, or bronchial glands; secondly, in thin strata, which are concentric and of a dead white, friable like the urinary calculi themselves; thirdly, of a more uniform texture like ivory. This ingredient is not affected by acids; and, with the blow-pipe, exhales the smell of animal matter, becoming white and friable. It is soluble in the nitric and muriatic acids, but insoluble in the vitriolic. The solutions afford also a calcareous oxalate, from which the existence of the lime is ascertained.

The *acid phosphat of lime* is chiefly confined to the bezoars, of which it is the principal substance. It is formed in thin strata, with little adhesion, and very brittle. In fusion it gives out a slight aromatic odour.

The *ammoniaco magnesian phosphat* is most easily recognised among the ingredients of calculi, though for a long time unknown. It sometimes occurs in white prismatic crystals, semitransparent, or in tables whose edges project, and form the little points on the surface of some urinary calculi, as well as on the intestinal bezoars of the elephant and the horse. At other times it is in sparry, lamellated strata, semitransparent, of different thickness, covering another primitive calculus, consisting of the uric acid, or some other body. The resemblance to calcareous spar is so strong, that Daubenton and Vicq. d'Azyr had nearly confounded it with this fossil. This salt is smooth to the eye and to the touch, easily reduced to a white light powder of a sweetish, insipid taste, without the dryness of phosphat of lime. This ingredient is easily dissolved in acids and alkalis, but contains some animal matter; and, when decomposed, leaves some soft, light, transparent, membranous flakes, more nearly approaching the primitive forms of the calculous fragments than those from the phosphat of lime, which also contains, though less strongly marked, similar membranous substances. It generally forms the external strata of urinary calculi, and the greater proportion of the intestinal bezoars of the horse, the elephant, and the larger mammalia; but is never discovered in *their* urinary calculi. After having been ascertained in the analysis of calculi, it was found in the urine; at first in the form of the magnesian phosphat, and, when the urine began to purify,

in that of the ammoniaco magnesian phosphat. This is the triple salt, formed in hexaedra prisms on the sides of the vessels in which urine has been suffered to stand, till it undergoes a spontaneous decomposition.

The *oxalate of lime* long eluded the investigation of chemists; but it is constantly found in the mulberry calculi, so called from their resembling that fruit in colour and pointed projections. This substance is hard like ivory; and, when sawed, exhales the faint odour of bones rubbed against each other. It consists of concentric laminæ applied in rounded scales, or like caps; which, successively covering each other, produce the projecting points. It contains an animal jelly, and is exclusively discovered in human urinary calculi.

*Carbonate of lime*, long supposed to be the only basis of the human urinary calculi, is not found in them. It only occurs in the urinary calculi of the other mammalia, particularly, horses, oxen, and pigs. It is neither in strata nor in crystals, but in confused irregular masses, consisting of granulated molecules.

*Flint* occurs very rarely. M. Fourcroy only found it twice in six hundred calculi, and then in small quantities, mixed with other substances. It is apparently accidental.

The *spermaceti* Fourcroy calls *adipocire*, as a medium between fat and wax, but not perfectly the same with that from the whale, as it is more dry and fusible. This substance often occurs in pure white, shining, talcylaminæ, or covered with a brown colouring matter. It is sometimes found only like little straws, passing through these concretions, occupying their centre, or deposited, on cooling, by the alcohol, in which the calculi have been immersed. It is soft and fat to the touch. When rubbed and warmed, the smell resembles that of suet, or the spermaceti of the whale: it is very light and swims on water. It is fusible in nearly the same temperature as the spermaceti, resembling, when melted, a yellow oil. It sublimes, like wax, at a temperature above its melting point. By distillation it affords water and acetous and sebaceous acids, as well as carbonated hydrogenous gas. Its kind of fusibility renders it less readily decomposed in an open fire than fat. It is not affected by acids, but forms a soap with alkalis. It is insoluble in water, soluble in alcohol, and in a larger proportion in hot than in cold spirit. The solution of the adipocire separates in shining crystals when cooled, and is decomposed by the addition of water. It dissolves in fixed oils, and in volatile ones slightly warmed. It is found only in the biliary calculi of men; often separate and pure in those calculi which are white and crystalline. It is not discovered in the biliary calculi of the ox and other mammalia hitherto examined.

The *animal bezoardic resin* we have already noticed, as much as its importance in this work merits.

The *gelatine* accompanies almost every ingredient. It is the connecting medium of the other bodies mentioned; and is discovered by the fetid odour they exhale in the fire by forming carbon frothing in water, which thus acquires an animal smell, and in being precipitated by tannin.

We have given this abstract of the more important parts of M. Fourcroy's Memoir, not only to illustrate this subject by the latest chemical investigations, but to contrast it with the experiments of Dr. Pearson, perhaps to reconcile the discordant observations.

Dr. Pearson, neglecting the more violent methods of analysis, dissolved the calculi in caustic alkalis, and precipitated the dissolved portions by acids. The precipitate, when well washed and dried, was a light micaceous crystalline substance, consisting of nearly one-half of the original calculus. It is without smell or taste; scarcely soluble in cold water; does not unite to any alkaline substance, except when uncombined and caustic; it is at least not an acid. It cannot be sublimed without decomposition, and consequently cannot be the *lithic* or *succinic acid*. It does not form a viscid solution with water, and consequently cannot be an animal mucilage. As in every trial it shows marks of an animal nature, Dr. Pearson styles it an animal oxide: according to this author, it is not putrescent or crystallizable, insoluble in cold water, producing a pink or a red residuum on evaporating its solution in nitrous acid. As an oxide he attempted to acidify it, but could only change it into ammonia and carbonic acid. He found that when the nitric solution of this animal oxide was evaporated, the inflammation which took place was owing to the production of nitrat of ammonia. The white, impalpable, tasteless, heavy powder left on the filter after the union of caustic soda, contained  $\frac{1}{3}$  of animal oxide;  $\frac{2}{3}$  of phosphat of lime; of ammonia, perhaps with phosphoric acid, mucilage, &c.  $\frac{2}{3}$ . Dr. Pearson afterwards separated the lithic acid of Scheele, and found its properties wholly different from the animal oxide. On examining two hundred specimens of urinary calculi, thirty-two out of thirty-three contained this oxide, but its proportion varied usually from 0.40 to 0.70; and it sometimes was found in the exterior, sometimes in the interior, laminæ. It was not, however, found in the urinary concretions of any animal but man. It is found also in the human arthritic calculi, but not in the concretions of the teeth, stomach, intestines, lungs, or brain. This animal oxide Dr. Pearson calls uric oxide.
